THE ENCYCLOPÆDIA BRITANNICA

FOURTEENTH EDITION

VOLUME 20

SARSAPARILLA TO SORCERY

SARSAPARILLA, a popular drug, prepared from the fibrous roots of several species of the genus *Smilax,* indigenous to Central America from the southern and western coasts of Mexico to Peru. Only two species have been identified with certainty. These are *Smilax officinalis* and *S. medica,* which yield respectively the so-called "Jamaica" and the Mexican varieties. They are large perennial dioecious climbers growing from short thick underground stems, from which rise numerous semi-woody flexuous angular stems, bearing large alternate stalked long-persistent and prominently net-veined leaves, from the base of which spring the tendrils which support the plant.

When boiled in water the root affords a dark extractive matter; boiling alcohol extracts a neutral substance in the form of crystalline prisms, which crystallize in scales from boiling water. This body, which is named *parillin,* is allied to the saponin of quillaia bark, from which it differs in not exciting sneezing. Sarsaparilla has a popular reputation as an "alterative," but is professionally regarded as inert and useless.

The varieties of sarsaparilla met with in commerce are the following: Jamaica, Lima, Honduras, Guatemala, Guyaquil and Mexican. Of these, differing in their character, the first-named yields the largest amount of extract, viz. from 33 to 44%; it is the only kind admitted into the British pharmacopoeia. On the Continent, especially in Italy, the varieties having a white starchy bark, like those of Honduras and Guatemala, are preferred.

SARSFIELD, PATRICK (?–1693), titular earl of Lucan, Irish Jacobite and soldier, belonged to an Anglo-Norman family long settled in Ireland. He was born at Lucan, but the date is unknown. His father Patrick Sarsfield married Anne, daughter of Rory (Roger) O'Moore, who organized the Irish rebellion of 1641. Patrick, who was a younger son, entered Dongan's regiment of foot on Feb. 9, 1678. During the last years of Charles II. he served in the English regiments which were attached to the army of Louis XIV. of France. The accession of King James II. led to his return home.

He took part in the suppression of the Western rebellion at the battle of Sedgemoor on July 6, 1685. In the following year he was promoted to a colonelcy. King James had adopted the dangerous policy of remodelling the Irish army so as to turn it from a Protestant to a Roman Catholic force, and Sarsfield, whose family adhered to the church of Rome, was selected to assist in this reorganization. When the king brought over a few Irish soldiers to coerce the English, Sarsfield came in command of them. As the king was deserted by his army there was no serious fighting, but Sarsfield had a brush with some of the Scottish soldiers in the service of the prince of Orange at Wincanton. When King James fled to France, Sarsfield accompanied him.

In 1689 he returned to Ireland with the king. During the earlier part of the war he did good service by securing Connaught, and was promoted to brigadier, and then major-general. After the battle of the Boyne (July 1, 1690), and during the siege of Limerick, Sarsfield came prominently forward. His capture of a convoy of military stores at one of the two places called Ballyneety between Limerick and Tipperary, delayed the siege of the town till the winter rains forced the English to retire. This achievement made him the popular hero of the war with the Irish. When the cause of King James was ruined in Ireland, Sarsfield arranged the capitulation of Limerick and sailed to France on Dec. 22, 1691. He received a commission as lieutenant-general (maréchal de camp) from King Louis XIV. and fought with distinction in Flanders till he was mortally wounded at the battle of Landen (Aug. 19, 1693). He died at Huy two or three days after the battle. In 1691 he had been created earl of Lucan by King James. He married Lady Honora de Burgh, by whom he had one son James, who died childless in 1718.

See J. Todhunter, *Life of Patrick Sarsfield* (1895).

SARTHE, a department of France, formed in 1790 out of the eastern part of Maine, and portions of Anjou and of Perche. Pop. (1926) 387,482. Area 2,410 sq.m. It is bounded north by the department of Orne, north-east by Eure-et-Loir, east by Loir-et-Cher, south by Indre-et-Loire and Maine-et-Loire and west by Mayenne. The department includes the greater part of the basin of the Sarthe, which drains the large bay in the southern flank of the hills of Normandy, and the city of Le Mans is at the focus of this bay, where the Sarthe from the north-west joins the Huisne from the north-east. It is floored largely by Jurassic and Cretaceous rocks succeeding one another eastward, with the Armorican Palaeozoics on its western border. South-east of the Huisne the Eocene deposits stand out, forming a relatively poor territory. The Loir flows through the southern edge of the department to join the Sarthe in Maine-et-Loire; along its chalky banks caves have been hollowed out which, like those along the Cher and the Loire, serve as dwelling-houses and stores. The

mean annual temperature is 51° to 52° F. The rainfall is between 25 and 26 in.

The department is mainly agricultural. There are three distinct districts:—the corn lands to the north of the Sarthe and the Huisne; the region of barren land and moor, partly planted with pine, between those two streams and the Loir; and the wine-growing country to the south of the Loir. Sarthe produces much barley and hemp. The raising of cattle and of horses, notably those of the Perche breed, prospers, and fowls and geese are fattened in large numbers for the Paris market. Apples are largely grown for cider. The chief forests are those of Bercé in the south and Perseigne in the north; the fields in the department are divided by hedges planted with trees. Coal, marble and freestone are among the mineral products. The staple industry is the weaving of hemp and flax, and cotton and wool-weaving are also carried on. Paper is made in several localities. Iron-foundries, copper and bell foundries, factories for provision-preserving, marble-works at Sablé, potteries, tile-works, glass-works and stained-glass manufactories, curriers, machine factories, wire-gauze factories, flour-mills are also important. The department is served by the Ouest-État, the Orléans and the State railways, and the Sarthe and Loir provide about 100 m. of waterway, though the latter river carries little traffic.

The department forms the diocese of Le Mans and part of the ecclesiastical province of Tours, has its court of appeal at Angers, and its académie (educational division) at Caen, and forms part of the territory of the IV. army corps, with its headquarters at Le Mans. The arrondissements are named from Le Mans, the chief town, La Flèche and Mamers. There are 33 cantons and 386 communes. The chief towns are Le Mans, La Flèche, La Ferté Bernard, Solesmes (*q.q.v.*), and Sablé.

SARTS. The Sarts are an Iranian Turkish tribe, numbering about 2,000,000, who live in Ferghana and Syr Daria territories. They are highly organized, living in permanent villages, with a developed Sufi system of education. They practise a system of agriculture, using irrigation canals, and growing fruit and cotton. They are also accomplished traders. In religion they are Sunnites, many of them belonging to the Sufi order. They have mixed considerably with the Tadjiks, the remnant of the old non-Turkic population, and physically are largely of the Alpine type. In culture they differ widely from most of the tribes speaking cognate languages. (L. H. D. B.)

SARWAT PASHA, ABDEL KHALEK (1873–1928), Egyptian statesman, was educated in Cairo, and became secretary to the Legal Control Commission. In 1905 he became vice-president of the native courts of Kena Province, and judge in the Cairo children's correctional court. In 1907 he was appointed governor of Assiut Province and in 1908 procureur-general of the native courts, a post which had for many years been filled by European officials. In 1914 he was appointed minister of justice in Rushdi Pasha's cabinet, formed after the declaration of a British protectorate. He resigned with Rushdi in 1919. In 1921 he joined Adly Pasha's cabinet as minister of the interior, and acted as prime minister during the latter's absence in London during the negotiations with Lord Curzon. The declaration of 1922, recognizing the independence of Egypt as a sovereign State, which, with the help of Lord Allenby, he was instrumental in obtaining, was a great success for him, and on March 21, 1922 he became prime minister. He resigned in Nov. 1922, because King Fuad claimed a greater degree of power than Sarwat Pasha could reconcile with the terms of the Constitution.

As Government candidate for the presidency of the Chamber in March 1925, he was defeated, and only took office again in June 1926, as minister for foreign affairs in Adly Pasha's cabinet. On the fall of Adly Pasha in April 1927, Sarwat Pasha, an independent like Adly, formed a new ministry. He came into conflict from time to time with his Wafdist supporters, and within a month of his appointment had to face the serious Anglo-Egyptian crisis resulting in the despatch of three British battleships to Egypt. (*See* EGYPT: *History*.) It is sufficient evidence of Sarwat Pasha's tact and ability that in his statement on his correspondence with Lord Lloyd and the conclusion of the dispute he was able to carry with him a majority of the Wafdist chamber of Deputies. He accompanied King Fuad to England on his visit to Europe in 1927, but his visit was interrupted by the death of Zaghlul Pasha, which obliged him to return to Egypt.

For the history of the Anglo-Egyptian negotiations of 1927–28 *see* EGYPT, *History*. The negotiations, which Sarwat continued again in London and concluded in Cairo resulted in the proposal of a treaty of alliance. This was rejected by the Wafd leaders, whom Sarwat consulted, and he then resigned (March, 1928). The king entrusted the formation of a new cabinet to Nahas Pasha, Zaghlul's successor in the leadership of the Wafd party. Sarwat Pasha died in Paris on Sept. 22, 1928.

SARZANA, a town and episcopal see of Liguria, Italy, in the province of Genoa, 9 m. E. of Spezia, on the railway to Pisa, at the point where the railway to Parma diverges to the north, 59 ft. above sea-level. Pop. (1921) 11,236 (town); 13,153 (commune). The handsome cathedral of white marble in the Gothic style, dating from 1204, was completed in 1471. It has a fine 12th cent. crucifix and other works of art. The old citadel, built by the Pisans in 1263 was re-erected by Lorenzo de' Medici in 1488. The castle of Sarzanello was built by Castruccio Castracani (d. 1328), whose tomb by the Pisan Giovanni di Balduccio is in S. Francesco. Glass bottles and bricks are made here.

Sarzana was the birthplace of Pope Nicholas V. Its position at the entrance to the valley of the Magra (anc. *Macra*), the boundary between Etruria and Liguria in Roman times, gave it military importance in the middle ages. It arose as the successor of the ancient Luna, 3 m. S.E.; the first mention of it is found in 983, and in 1202 the episcopal see was transferred hither.

SĀSANA VAMSA, a history of the Buddhist order in Burma, which was composed, in that country, by Paññā-sāmi in 1861. It is written in Pali prose; and is based on earlier documents, in Pali or Burmese, still extant, but not yet edited. The earlier part of the work deals with the history of Buddhism outside of Burma. This is based on the Mahāvamsa (*q.v.*) and other well-known Ceylon works; and has no independent value. The latter part of the work, about three-fifths of the whole, deals with Buddhism in Burma, and contains information not obtainable elsewhere. It was edited for the Pali Text Society in 1897 by Dr. Mabel Bode.

SASARAM, a town of British India, in the Shahabad district of Behar and Orissa, with a station on the East Indian railway. Pop. (1921), 22,308. It is famous as containing the tomb of the emperor Sher Shah (1540–1545). The tomb, which is the finest example of Pathan architecture in India, with a dome 101 ft. high, stands on an island in the middle of an artificial lake. The town also contains the tomb of Sher Shah's father, another fine specimen of Pathan art; a building called the Kila, or fort, said to have been his palace; and the grave and unfinished tomb of Sher Shah's son, the emperor Salim Shah. Outside is the ruined tomb of Alawal Khan, the reputed architect of Sher Shah's and his father's tomb. A rock edict of Asoka is inscribed on the Chandan Pir Shahid hill, close to the town.

SASKATCHEWAN. The middle member of the three Prairie Provinces of Canada, lies between 60° N. and 49° N. and 110° W. and 102° W. Physiographically it is divisible into two main areas by a line from about 53° 30′ N. on the eastern border (just south of Cumberland Lake) to 56° 30′ N. (just south of Buffalo Lake), on the west, *i.e.*, a line running somewhat to the south of the course of the Churchill River within the Province. The area to the north of this line comprising about one-third of the Province is a lowland—mostly over 1,000 ft. but under 1,200 ft.—developed upon Pre-Cambrian Rocks, with a narrow border of Palaeozoic sedimentaries along its southern margin. The Pre-Cambrian, *i.e.*, Laurentian Shield area is a hummocky wilderness of rock, lake, forest and swamp, with drainage to the Mackenzie system in L. Athabasca to the north, and to the Hudson Bay system via the Churchill River, to the south. This northern area has a wealth of timber, pulp wood, water power and probably metallic minerals at present untouched. Surface, and to some extent, climatic conditions, are such as to preclude any immediate likelihood of farming development, and north of

the Churchill River—if we except a limited quantity of merchantable timber in the valley of the Clearwater and about the shores of L. Athabasca—even the forests have at present little value except as a game and fur-bearing animal reserve. South of the Churchill River to the latitude of Prince Albert, there is on the Saskatchewan a commercial forest belt which, because of muskeg and fires, contains little saw timber, but is about 25% covered with potential pulp wood. This commercial timber belt overlaps the southern physiographic division which differs from the northern, (i.) in being higher (1,700 ft–2,000 ft. in the north to over 3,000 ft. in the extreme south-west); (ii.) in being developed on little disturbed sedimentaries of Cretaceous age, with some plateau-like tertiary residuals; (iii.) in the tabular nature of its major land forms.

The rise from the northern limits of this Cretaceous tableland is not quite gradual to the south-west, but is interrupted by extensive plateau masses rising some 500 ft.–800 ft. above the general levels. Such are Moose Mts., Beaver Hills and Bear Hills. An irregular but generally perceptible low scarp facing north-east runs from Estevan on the United States border to about Battleford—a continuation of the Missouri *coteau* of the United States. South-west of this line the plateau is higher—a part of the so-called third prairie steppe—and in the extreme south is itself overtopped by Cypress Hills and Wood Mts., scrub-covered plateau-like masses developed on tertiary sedimentaries. Apart from these last and a belt of grove country in the north, the land south of the north Saskatchewan river is unforested. The larger rivers, *e.g.*, the north and south Saskatchewan, flow in trench-like courses and glaciation has left its trace in innumerable lakes, abandoned *coulées*, and a general mantle of drift which thins out on the higher plateau.

Precipitation over most of the Province is between 13 in.–18 in. and over 60% occurs in the growing season (May–September). In the south-west of the Province—between the south Saskatchewan and the Cypress Hills—precipitation is, relative to evaporation, too low for effective farming. Here and on the Wood and Cypress Hill areas, open land is best used for ranching. However, the larger part of the prairie area has proved abundantly suitable for wheat farming, while mixed farming and dairy farming are developing in the northern parts of the prairie and in the grove belt. Saskatchewan leads the Prairie Provinces in agricultural production, including dairy farming, which has now assumed a very great importance. In the prairie belt the summers are a little hotter than in south-east England, but drier and much brighter. The winters are intensely cold, but dry, bright and invigorating. Rapid variations in temperature are frequent, especially in winter. The snow cover is very light.

Lignite is mined (472,000 tons in 1925) near Estevan in S. Saskatchewan. The Province has 1,087,756 h.p. water power (undeveloped) chiefly on the Lower Churchill, Saskatchewan, Reindeer and Black rivers, all in the Northern unpopulated part of the Province and too remote for immediate development.

In the settled prairie portion of the Province there is now a fairly dense network of railway.

Statistics of Principal Crops

	1920		1926		1927 (estimated only)	
	Area 000 ac.	Yield 000 bu.	Area 000 ac.	Yield 000 bu.	Area 000 ac.	Yield 000 bu.

History, Administration, Etc.—In 1905 the Dominion Government created out of the North West Territories the Provinces of Alberta and Saskatchewan. In the decade 1911–21 population in Saskatchewan increased 439%—representing one of the greatest rushes for farm lands in the history of the world. The Provincial Government is vested in a Lieutenant-Governor and a Legislative Assembly of 63 members elected for five years. Women are enfranchised and eligible for election to the Legislature. Regina is the seat of Government. The Province is represented by six Senators and twenty-one members of Parliament in the Dominion Government.

Population and Racial Origin, 1926.—British, 416,721; German, 96,498; Scandinavian, 63,370; Ukrainian, 51,474; French, 47,030; Russian, 36,208; others, 109,437; total, 820,738; in 1931 the population was 921,785. (*See* also CANADA.)

SASKATCHEWAN ("Rapid River"), a river of Alberta and Saskatchewan provinces, Canada. Two large streams known as the North and South Saskatchewan unite near Prince Albert, and thence flow east into Lake Winnipeg. The North Saskatchewan rises in the Rocky Mountains in 52° 07′ N. and 117° 06′ W., and flows east, receiving several important tributaries, including the Clearwater, Brazeau and Battle. The South Saskatchewan is formed by the union of the Bow and the Belly, the former and larger of which rises in western Alberta in one of the highest districts of the Rockies. Flowing east it receives the waters of the Red Deer, and farther on turns abruptly north to its junction with the other branch. The length of the united Saskatchewan is about 300 m. It is little used now for navigation.

SASKATOON, second largest city of the Province of Saskatchewan, Canada, is situated on the bank of the South Saskatchewan river, 160 m. N.W. of Regina and 466 m. W. of Winnipeg. From a population of 113 in 1900 it increased to 25,739 in 1921 and 43,291 in 1931. It is an important railway centre for the Canadian Pacific and Canadian National railways and the mid-western headquarters of the latter line. Its central geographical position in the province gives it freight control of about 47,000 sq.m. of distributing territory. It is the seat of the University of Saskatchewan (1,330 regular students in 1927), of the provincial agricultural school and experiment farm, and of a newly built provincial normal school. There are 12 large public schools (attendance 8,645 in 1926), 17 churches, 5 banks, a court house, customs house, Dominion land office, land title office and 2 hospitals. The city owns electric light and power, street railway, water and sewerage systems. The assessed value of taxable property in 1926 was $28,327,600. The city is the second largest manufacturing city in the province with 47 establishments in 1925 producing goods valued at $7,184,543. The chief industries were the manufacturing of flour, breakfast foods, tractors, garments, beer, bricks and cement blocks. There are also a number of large wholesale houses, the Dominion interior elevator (capacity, 3,500,000 bu.), and two daily and one weekly newspapers.

SASSAFRAS (*Sassafras variifolium*), a North American tree of the laurel family (Lauraceae), called also ague-tree, with aromatic bark and foliage. It is native to sandy soils from Maine to Ontario and Iowa and south to Florida and Texas. While usually a small tree, it sometimes attains a height of 80 ft. or more. It has furrowed bark, bright green twigs and entire, mitten-shaped or three-lobed leaves, the three forms often on the same twig. The yellow flowers, borne in small clusters, are followed by dark blue berries. The root, especially its bark, is used in household medicine; it yields oil of sassafras, used in perfumery. (*See* OREGON MYRTLE; SPICE-BUSH.)

SASSANID or SASSANIAN DYNASTY (or SASANIAN), the ruling dynasty of the neo-Persian empire founded by Ardashir I. in A.D. 226 and destroyed by the Arabs in 637. The dynasty is named after Sāsān, an ancestor of Ardashir I. *See* PERSIA: CALIPHATE.

SASSARI, a town and archiepiscopal see of Sardinia, capital of the province of Sassari, situated in the N.W. corner of the island, 12½ m. by rail S.E. of Porto Torres on the north coast, and 21½ m. N.W. of Alghero on the west coast, 762 ft. above sea-level. Pop. (1921) 36,807 (town); 42,946 (commune). The town has a modern aspect, with spacious streets and squares. S. Maria di Betlemme has a good façade and Romanesque portal of the end of the 13th century. The museum in the university has an interesting collection of antiquities from all parts of the

island, and belonging to the prehistoric, Phoenician and Roman periods. Sassari is connected by rail by a branch (28½ m. E.S.E. to Chilivani) with the main line from Cagliari to Golfo degli Aranci, and with Porto Torres and Alghero. Eleven m. to the east is the Trinità di Saccargia (12th cent.) with a lofty campanile, one of the finest Pisan churches in the island.

The name, in the form Thatari, first occurs in the 12th century A.D. when a church of S. Nicola is mentioned. The town was in existence in 1217, when a body of Corsicans, driven out of their island by the cruelties of a Visconti of Pisa, took refuge there, and gave their name to a part of it. In 1288, four years after the defeat of Meloria, Pisa ceded Sassari to Genoa; but Sassari enjoyed internal autonomy, and in 1316 published its statutes (still extant), which are perhaps in part the reproduction of earlier ones. In 1323, however, Sassari submitted to the Aragonese king. The episcopal see was transferred here from Porto Torres in 1441. It was sacked by the French in 1527.

See P. Satta-Branca, *Il Comune di Sassari nei secoli XIII. e XIV.* (Rome, 1885).

SASSINA (mod. *Sarsina*), an ancient town of Umbria, Italy, on the left bank of the river Sapis (Savio), 16 m. S. of Caesena (Cesena). In 266 B.C. both consuls celebrated a triumph over the Sassinates, and in the enumeration of the Italian allies of the Romans in 225 B.C. the Umbri and Sassinates are mentioned, on an equal footing, as providing 20,000 men between them. The poet Plautus was a native of Sassina (b. 254 B.C.). An episcopal see was founded here in the 3rd century A.D. and still exists. The present town has 1,751 inhabitants (commune, 4,431).

SASSOON, SIR ALBERT ABDULLAH DAVID, Bart, cr. 1890 (1818–1896), British Indian philanthropist and merchant, was born at Baghdad on July 25, 1818, a member of a Jewish family settled there since the beginning of the 16th century, and previously in Spain. His father, a leading Baghdad merchant, was driven by repeated Anti-Semitic outbreaks to remove from Baghdad to Bushire, Persia, and, in 1832, he settled in Bombay where he founded a large banking and mercantile business. Albert Sassoon was educated in India, and on the death of his father became head of the firm. He was a great benefactor to the city of Bombay, among his gifts being the Sassoon dock, completed in 1875. He died at Brighton, England, on Oct. 24, 1896.

SASTRI, V. S. SRINIVASA (1869–), Indian statesman, was born of poor Brahmin parents at Valangiman, near Kumbakonam, Madras, on Sept. 22, 1869. He started life as a schoolmaster, but, deeply impressed by the rules of the Servants of India Society which G. K. Gokhale founded in 1905, on a basis of self-sacrifice, purity and poverty, he was admitted to membership early in 1907. On Gokhale's nomination, made before his death in 1915, Sastri succeeded to the presidentship. Elected to the viceregal legislative council in 1916, he soon came to the front as the greatest Indian orator of his day. He gave discriminating support to the Montagu-Chelmsford reforms, being a member of the Moderate deputation to England in 1919 and serving on Lord Southborough's Franchise committee; he was elected a member of the new Council of State when the reforms took effect. In 1921 he served on the Indian Railway committee; represented India at the Imperial Conference in London, at the League of Nations Assembly at Geneva, and at the Washington Conference on the reduction of naval armaments. The same year he was called to the privy council, being the third Indian to receive this distinction, and was made a freeman of the City of London. In 1922 he was deputed to Australia, New Zealand and Canada to confer with the respective governments as to the best methods of practical interpretation of the resolution of the 1921 Imperial Conference on the rights of citizenship of lawfully domiciled Indians, and he achieved definite results. He was chairman of a deputation of non-official members of the Indian legislature to London in 1923 to support representations made by the Indians of Kenya on their disabilities, and certain disappointments led him some way in the direction of aloofness; but in 1926 he accepted an invitation of the Government of India to be a member of the Indian delegation to South Africa for a round table conference with the Union Government.

A settlement was reached and with the hearty approval of Gandhi, Sastri accepted early in 1927 appointment as the first agent-general to the Government of India in South Africa. He showed great judgment and skill in promoting good will and concord during the two years to which he limited his acceptance.

(F. H. Br.)

SATARA, a town and district of British India, in the Central division of Bombay, 10 m. from Satara Road station on the Madras and Southern Mahratta railway. The name is derived from the "seventeen" walls, towers and gates which the fort was supposed to possess. The town is 2,320 ft. above sea-level, near the confluence of the rivers Kistna and Vena, 56 m. S. of Poona. Pop. (1921) 22,454.

The District of Satara has an area of 4,916 sq.m. It contains two hill systems, the Sahyadri, or main range of the Western Ghats, and the Mahadeo range and its offshoots. The former runs through the district from north to south, and the latter from east to south-east. The Mahadeo hills are bold, presenting bare scarps of black rock. There are two river systems—the Bhima system in a small part of the north and north-east, and the Kistna system throughout the rest of the district. The hill forests have a large store of timber and firewood. The soil is a black loamy clay containing carbonate of lime, which is very fertile when well watered. Satara contains some important irrigation works, including the Kistna canal. In some of the western parts of the district the average annual rainfall exceeds 200 in.; but on the eastern side water is scanty. The population in 1921 was 1,026,259. The principal crops are millet, pulse, oil-seeds and sugar-cane. The only manufactures are cotton cloth, blankets and brass-ware. The district is traversed from north to south by the Madras and Southern Mahratta railway, passing 10 m. from Satara town. The Satara agency comprises the two feudatory states of Phaltan and Aundh (*q.v.*).

On the overthrow of the Jadhav dynasty in 1312 the district passed to the Mohammedan power, which was consolidated in the reign of the Bahmani kings. On the decline of the Bahmanis towards the end of the 15th century the Bijapur kings finally asserted themselves, and under these kings the Mahrattas arose and laid the foundation of an independent kingdom with Satara as its capital. The Peshwas, who removed the capital to Poona and degraded the raja, got the ascendancy in the 18th century, but after the war of 1817 the British restored the raja, and assigned to him the principality of Satara, with an area much larger than the present district. In consequence of political intrigues he was deposed in 1839, and his brother, who took his place, died without male heirs in 1848, when the state was resumed by the British government.

SATEEN, a term of modern usage derived from "satin" (*q.v.*). The term "sateen" is employed more especially to distinguish cotton textures that are based on the satin weave principle of fabric structure from those of the true "satin" fabrics produced from pure silk.

SATELLITE, in astronomy, a small opaque body revolving around a planet, as the moon around the earth (*see* Planet and the articles on individual planets). In the theory of cubic curves, Arthur Cayley defined the satellite of a given line to be the line joining the three points in which tangents at the intersections of the given (primary) line and curve again meet the curve.

SATIE, ERIK LESLIE (1866–1925), French composer, was born at Honfleur on May 17, 1866 (his mother being an Englishwoman), and studied at the Paris conservatoire. His early works proclaimed a persistent determination to be original, and were followed by a series of equally eccentric pianoforte pieces. He exercised influence, none the less, upon many of his younger French contemporaries of the "advanced" school, who hailed him as a prophet. But the public at large saw in him something of the *farceur,* and his interesting attempts to be daring did not seem to be accompanied by any commensurate genuine talent.

See A. Coeuroy, *La Musique française moderne* (Paris, 1922).

SATIN, a term strictly denoting a true silk texture developed with a perfectly even, smooth and glossy or lustrous surface on which either warp or weft threads preponderate and

thus entirely obscure the other series of threads. The principle of fabric structure observed in the construction of satin fabrics is that known as the "satin" weave, which constitutes one of the simplest elementary weaves in which the intersections of the warp and weft threads are so evenly and perfectly distributed that there are no pronounced textural features discernible in the fabric, as the threads, either of warp or of weft only, are displayed on the surface with the least possible amount of deflection by their interlacement with the threads of the other system.

A true silk satin fabric may be produced either with a warp surface or a weft surface of pure silk, with the reverse side of cotton or other textile material. In either case, the silk requires to be of the best quality and perfectly even.

The term "satin," however, is now applied as a general description for many fabrics (other than those composed of pure silk), constructed on the principle of the satin weaves. For example, cotton fabrics constructed on the satin-weave basis are described as "satin" or "sateen" according to whether they are developed with a warp surface or a weft surface, respectively. It is also applied indiscriminately to many other varieties of fabrics having a smooth and lustrous finish. (For Satinet *see* SATEEN.) (H. N.)

SATIN-SPAR, a name given to certain fibrous minerals which exhibit, especially when polished, a soft satiny or silky lustre, and are therefore sometimes used as ornamental stones. Such fibrous minerals occur usually in the form of veins or bands, having the fibres disposed transversely. The most common kind of satin-spar is a white finely-fibrous gypsum not infrequently found in the Keuper marls of Nottinghamshire and Derbyshire, and used for beads, etc. Other kinds of satin-spar consist of calcium carbonate, in the form of either aragonite or calcite, these being distinguished from the fibrous gypsum by greater hardness and effervescence with acids and from each other by specific gravity and optical characters. The satin-spar of Alston, Cumberland, is a finely-fibrous calcite occurring in veins in a black shale of the Carboniferous series.

SATIN-WOOD, a beautiful light-coloured hard wood, having a rich, silky lustre, sometimes finely mottled or grained, the produce of a moderate-sized tree, *Chloroxylon Swietenia* (family Meliaceae), native of India and Ceylon. A similar wood, known under the same name, is obtained in the West Indies, the tree being probably a species of *Xanthoxylum* (family Rutaceae). Satin-wood was in request for rich furniture about the end of the 18th century, the fashion then being to ornament panels of it with painted medallions and floral scrolls and borders. It is used for inlaying and small veneers.

SATIRE, in its literary aspect, may be defined as the expression in adequate terms of the sense of amusement or disgust excited by the ridiculous or unseemly, provided that humour is a distinctly recognizable element, and that the utterance is invested with literary form. Without humour, satire is invective; without literary form, it is mere clownish jeering. The first exercise of satire no doubt consisted in gibing at personal defects. To dignify satire by rendering it the instrument of morality or the associate of poetry was a development implying considerable advance in the literary art. In the accounts that have come down to us of the writings of Archilochus, the first great master of satire, we seem to trace the elevation of the instrument of private animosity to an element in public life. Simonides of Amorgus and Hipponax were distinguished like Archilochus for the bitterness of their attacks on individuals, with which the former combined a strong ethical feeling and the latter a bright active fancy. The loss of their writings, which would have thrown great light on the politics as well as the manners of Greece, is to be lamented. With Hipponax the direct line of Greek satire is interrupted; but two new forms of literary composition, capable of being the vehicles of satire, almost simultaneously appear. Although the original intention of fable does not seem to have been satirical its adaptability to satiric purposes was soon discovered. A far more important step was the elevation of the rude fun of rustic merrymakings to a literary status by the evolution of the drama from the Bacchic festival. The means had now been found of allying the satiric spirit with exalted poetry, and their union was consummated in the comedies of Aristophanes.

A rude form of satire had existed in Italy from an early date in the shape of the Fescennine verses, the rough and licentious pleasantry of the vintage and harvest. As in Greece, these eventually were developed into a rude drama. Verse, "like to the Fescennine verses in point of style and manner," was added to accompany the mimetic action, and these probably improvised compositions were entitled *Saturae,* a term denoting *miscellany,* and derived from the *satura lanx,* "a charger filled with the first-fruits of the year's produce."

The Roman people thus had originated the name of satire, and, in so far as the Fescennine drama consisted of raillery and ridicule, possessed the thing also; but it had not yet assumed a literary form among them. The real inventor of Roman satire is Gaius Lucilius (148–103 B.C.). The fragments of Lucilius preserved are scanty, but the verdict of Horace, Cicero and Quintilian demonstrates that he was a considerable poet. It is needless to dwell on compositions so universally known as the *Satires* of Lucilius's successor Horace, in whose hands this class of composition received a new development, becoming genial, playful and persuasive. The didactic element preponderates still more in the philosophical satires of Persius. Yet another form of satire, the rhetorical, was carried to the utmost limits of excellence by Juvenal, the first example of a great tragic satirist. Nearly at the same time Martial, improving on earlier Roman models now lost, gave that satirical turn to the epigram which it only exceptionally possessed in Greece, but has ever since retained. About the same time another variety of satire came into vogue, destined to become the most important of any. The Milesian tale, a form of entertainment probably of Eastern origin, grew in the hands of Petronius and Apuleius into the satirical romance, immensely widening the satirist's field and exempting him from the restraints of metre. Petronius's "Supper of Trimalchio" is the revelation of a new vein, never fully worked till our days. As the novel arose upon the ruins of the epic, so dialogue sprang up upon the wreck of comedy. In Lucian comedy appears adapted to suit the exigencies of an age in which a living drama had become impossible. With him antique satire expires as a distinct branch of literature.

In the Byzantine empire, indeed, the link of continuity is unbroken, and such raillery of abuses as is possible under a despotism finds vent in pale copies of Lucian. The first really important satire, however, of the middle ages, is a product of western Europe, recurring to the primitive form of fable, upon which, nevertheless, it constitutes a decided advance. *Reynard the Fox* (*see* FABLE), a genuine expression of the shrewd and homely Teutonic mind, is a landmark in literature. It gave the beast-epic a development of which the ancients had not dreamed. About the same time, probably, the popular instinct, perhaps deriving a hint from Rabbinical literature, fashioned Morolf, the prototype of Sancho Panza, the incarnation of sublunar mother-wit contrasted with the starry wisdom of Solomon; and the *Till Eulenspiegel* is a kindred Teutonic creation, but later and less significant. *Piers Ploughman,* the next great work of the class, adapts the apocalyptic machinery of monastic and anchoritic vision to the purposes of satire. The clergy were scourged with their own rod by a poet and a Puritan too earnest to be urbane. The Renaissance, restoring the knowledge of classic models, enlarged the armoury of the satirist. Partly, perhaps, because Erasmus was no poet, the Lucianic dialogue was the form in the ascendant of his age. Erasmus not merely employed it against superstition and ignorance with infinite and irresistible pleasantry, but fired by his example a bolder writer, untrammelled by the dignity of an arbiter in the republic of letters. The ridicule of Ulric von Hutten's *Epistolae obscurorum virorum* is annihilating, and the art of putting the ridicule into the mouth of the victim, is perhaps the most deadly shaft in the quiver of sarcasm. It was afterwards used with even more pointed wit though with less exuberance of humour by Pascal. Sir Thomas More cannot be accounted a satirist, but his idea of an imaginary commonwealth embodied the germ of much subsequent satire.

In the succeeding period politics take the place of literature and

religion, producing in France the *Satyre Ménippée*, elsewhere the satirical romance as represented by the *Argenis* of Barclay, which may be defined as the adaptation of the style of Petronius to State affairs. In Spain, where no freedom of criticism existed, the satiric spirit took refuge in the *novela picaresca,* the prototype of Le Sage and the ancestor of Fielding; Quevedo revived the mediaeval device of the vision as the vehicle of reproof; and Cervantes's immortal work might be classed as a satire were it not so much more. About the same time we notice the appearance of direct imitation of the Roman satirists in English literature in the writings of Donne, Hall and Marston. The prodigious development of the drama at this time absorbed much talent that would otherwise have been devoted to satire proper. Most of the great dramatists of the 17th century were more or less satirists, Molière perhaps the most consummate that ever existed; but, with an occasional exception like *Les Précieuses ridicules,* the range of their works is too wide to admit of their being regarded as satires. The next great example of unadulterated satire is Butler's *Hudibras.* Dignified political satire, bordering on invective, was carried to perfection in Dryden's *Absalom and Achitophel.* In France Boileau was long held to have attained the *ne plus ultra* of the Horatian style in satire and of the mock-heroic, but Pope was soon to show that further progress was possible in both. The polish, point and concentration of Pope remain unsurpassed, as do the amenity of Addison and the daring yet severely logical imagination of Swift; while the *History of John Bull* places their friend Arbuthnot in the first rank of political satirists.

The 18th century was, indeed, the age of satire. Serious poetry had for the time worn itself out; the most original geniuses of the age are decidedly prosaic, and Pope, though a true poet, is less of a poet than Dryden. In process of time imaginative power revives, but meanwhile Fielding and Smollett have fitted the novel to be the vehicle of satire and much beside, and the literary stage has for a time been almost wholly engrossed by a colossal satirist, a man who has dared the universal application of Shaftesbury's maxim that ridicule is the test of truth. The world had never before seen a satirist on the scale of Voltaire, nor had satire ever played such a part as a factor in impending change. As a master of sarcastic mockery he is unsurpassed; his manner is entirely his own; and he is one of the most intensely national of writers, notwithstanding his vast obligations to English humorists, statesmen and philosophers. English humour also played an important part in the literary regeneration of Germany, where Lessing, imbued with Pope but not mastered by him, showed how powerful an auxiliary satire can be to criticism. Another great German writer, Wieland, owes little to the English, but adapts Lucian and Petronius to the 18th century with playful if somewhat mannered grace. Goethe and Schiller, Scott and Wordsworth, are now at hand, and as imagination gains ground satire declines. Byron, who in the 18th century would have been the greatest of satirists, is hurried by the spirit of his age into passion and description, bequeathing, however, a splendid proof of the possibility of allying satire with sublimity in his *Vision of Judgment.* Two great satiric figures remain—one representative of his nation, the other most difficult to class. In all the characteristics of his genius Thackeray is thoroughly English; his satire is a thoroughly British article, a little solid, a little wanting in finish, but honest, weighty and durable. But Heine hardly belongs to any nation or country, time or place. In him the satiric spirit, long confined to established literary forms, seems to obtain unrestrained freedom.

In no age was the spirit of satire so generally diffused as in the 19th century, but many of its eminent writers, while bordering on the domains of satire, escape the definition of satirist. The term cannot be properly applied to Dickens, the keen observer of the oddities of human life; or to George Eliot, the critic of its emptiness when not inspired by a worthy purpose; or to Balzac, the painter of French society; or to Trollope, the mirror of the middle classes of England. If *Sartor Resartus* could be regarded as a satire, Carlyle would rank among the first of satirists; but the satire, though very obvious, rather accompanies than inspires the composition. The number of minor satirists of merit, on the other hand, is legion. James Russell Lowell's *Biglow Papers* represent perhaps the highest moral level yet attained by satire. Mallock, in his *New Republic,* made the most of personal mimicry, the lowest form of satire; Samuel Butler (*Erewhon*) holds an inverting mirror to the world's face with imperturbable gravity; the humour of Bernard Shaw has always an essential character of satire—the sharpest social lash. One remarkable feature of the modern age is the union of caricature (*q.v.*) with literature.

(R. G.; X.)

SATISFACTION, reparation for an injury or offence; payment, pecuniary or otherwise, of a debt or obligation; particularly, in law, an equitable doctrine of much importance. In English law, as between strangers, it was laid down in *Talbot* v. *Duke of Shrewsbury,* 1714, Pr. Ch. 394, that where a debtor bequeaths to his creditor a legacy as great as, or greater than the debt, the legacy shall be deemed a satisfaction of the debt. If the debt was incurred after the execution of the will, there is no satisfaction, nor is there where the will giving the legacy contains a direction to pay debts. As between parent and child, the doctrine operates (*a*) in the satisfaction of legacies by portions, and (*b*) of portions by legacies. In the case of (*a*), it has been laid down that where a parent, or one acting *in loco parentis,* gives a legacy to a child, without stating the purpose for which he gives it, it will be understood as a portion; and if the father afterwards advance a portion on the marriage, or preferment in life, of that child, though of less amount, it is a satisfaction of the whole, or in part. This application of the doctrine is based on the maxim that "equality is equity," as is also the rule (*b*) that where a legacy bequeathed by a parent, or one *in loco parentis,* is as great as, or greater than, a portion or provision previously secured to the child, a presumption arises that the legacy was intended by the parent as a complete satisfaction. In the United States some jurisdictions refuse to presume that a gift to a creditor is intended as a satisfaction of a debt. The testator's intention that the bequest shall operate as a satisfaction of the debt must appear upon the face of the will. A few States have abolished the doctrine of satisfaction by statute. (*See* Accord and Satisfaction; Legacy. For the theological meaning *see* Atonement.)

SATPURA, a system of hills in the centre of India. Beginning at the lofty plateau of Amarkantak, the range extends westward almost to the west coast. From Amarkantak an outer ridge runs south-west for about 100 m. to the Saletekri hills in Balaghat district. As it proceeds westward the range narrows from a broad tableland to two parallel ridges enclosing the valley of the Tapti, as far as the famous hill-fortress of Asirgarh. Beyond this point the Khandesh hills, which separate the valley of the Narbada from that of the Tapti, complete the chain as far as the Western Ghats. The mean elevation is about 2,500 ft.; but the plateaux of Amarkantak and Chauradadar in the east of Mandla district rise to nearly 3,500 ft., and many of the peaks and some of the tablelands exceed this altitude. Just east of Asirgarh there is a break in the range, through which passes the railway from Bombay to Jubbulpore, the elevation at this point being about 1,240 ft. The length of the system is about 600 m.

SATRAE, in ancient geography, a Thracian people, inhabiting part of Mount Pangaeus between the rivers Nestus (Mesta) and Strymon (Struma). According to Herodotus (vii. 110–112), they were independent in his time, and had never been conquered within the memory of man. They dwelt on lofty mountains, and on the highest of these was an oracle of Dionysus, whose utterances were delivered by a priestess. They were the chief workers of the gold and silver mines in the district. Herodotus is the only ancient writer who mentions the Satrae, and Tomaschek regards the name not as that of a people but of the warlike nobility among the Thracian Dii and Bessi. J. E. Harrison and others identify them with the Satyri (Satyrs), the attendants and companions of Dionysus, and also with the Centaurs.

See J. E. Harrison, *Prolegomena to the Study of Greek Religion* (1903), p. 379; W. Tomaschek, *Die alten Thraker* (1893).

SATRAP, in ancient history, the name given by the Persians to the governors of the provinces; Pers. *Khshatrapāvan, i.e.,* "protector (superintendent) of the country (or district)," Heb. *sakhshadrapan,* Gr. ἐξαιτράπης (insc. of Miletus, *Sitzungsber.*

Berl. Ak., 1900, 112), ἐξαιτραπεύων (insc. of Mylasa, Dittenberger, Sylloge, 3rd ed., 167) ἐξατράπης (insc. of Mylasa, Lebas, iii. 388, Theopomp, p. 111), shortened into σατράπης. By the earlier Greek authors (Herodotus, Thucydides, and often in Xenophon) it is rendered by ὕπαρχος "lieutenant, governor," in the documents from Babylonia and Egypt and in Ezra and Nehemiah by *pakha*, "governor"; and the satrap Mazaeus of Cilicia and Syria in the time of Darius III. and Alexander (Arrian, iii. 8) calls himself on his coins "Mazdai, who is [placed] over the country beyond the Euphrates and Cilicia." Cyrus the Great divided his empire into provinces; a definitive organization was given by Darius, who established twenty great satrapies and fixed their tribute (Herodot. iii. 89, sqq.). The satrap was the head of the administration of his province; he collected the taxes, controlled the local officials and the subject tribes and cities, and was the supreme judge of the province to whose "chair" (Nehem. iii. 7), every civil and criminal case could be brought. He was responsible for the safety of the roads (*cf.* Xenophon, *Anab.*, i. 9. 13), and had to put down brigands and rebels. He was assisted by a council of Persians, to which also provincials were admitted; and was controlled by a royal secretary and by emissaries of the king (esp. the "eye of the king"). The regular army of his province and the fortresses were independent of him and commanded by royal officers; but he was allowed to have troops in his own service (in later times mostly Greek mercenaries). The great provinces were divided into many smaller districts, the governors of which are also called satraps and hyparchs. The distribution of the great satrapies was changed occasionally, and often two of them were given to the same man. When the empire decayed, the satraps often enjoyed practical independence, especially as it became customary to appoint them also as generals-in-chief of their army district, contrary to the original rule. Hence rebellions of satraps became frequent from the middle of the 5th century; under Artaxerxes II. occasionally the greater part of Asia Minor and Syria were in open rebellion. The last great rebellions were put down by Artaxerxes III. The satrapic administration was retained by Alexander and his successors, especially in the Seleucid empire, where the satrap generally is designated as *strategus;* but their provinces were much smaller than under the Persians.

See further PERSIA: *Ancient History*, from the Achaemenid period onwards, and works there quoted. (ED. M.)

SATRICUM (mod. *Conca*), an ancient town of Latium, situated on a low hill surrounded by cliffs, some 30 m. to the S.E. of Rome, in a low-lying region to the south of the Alban hills, to the north-west of the Pomptine marshes. It was accessible direct from Rome by a road running more or less parallel to the Via Appia, to the south-west of it. It was a member of the Latin league of 499 B.C. and became Volscian in 488.

SATUN or SETUL, a small Siamese State in the Malay peninsula. Area 1,000 sq.m.; pop. 25,000. The principal production is pepper. (*See* also MALAY STATES: *Siamese.*)

SATURN, SATURNUS, SAETURNUS, a Roman god of sowing, or of seed-corn (*Satus*), identified with Cronos (*q.v.*), for reasons no longer apparent. His cult was so over-laid with Greek features that almost nothing is known of its original form. His cult-partner was the very obscure goddess Lua (*lues*, plague or destruction); she was amongst other things a fire-goddess in whose honour spoils were sometimes burned (*see* Rose in *Class. Rev.*, xxxvi., p. 15 *et seq.*). But, since for some reason Ops, the cult-partner of Consus (*q.v.*) became identified with Rhea, Saturn is often associated with her.

His temple stood at the foot of the *clivus Capitolinus* leading from the Forum, where the ruins of a late restoration of it are still visible. It contained the Republican treasury (*aerarium Saturni*). The statue had woollen bands around its feet, probably to keep it from running away (so at Sparta the statue of Enyalius the war-god was fettered, and there are plenty of savage parallels), *see* Macrob. *Saturn*, i. 8, 5; this too is Greek, for cult-statues are not native Roman. Also the worship was *Graeco ritu, i.e.*, with the head uncovered, not wrapped in the toga as was the Roman custom. His great festival was the Saturnalia, originally Dec. 19, but gradually extended to seven days. We may conjecture that it was connected with the winter sowing, which in modern Italy lasts in various districts from October to January. Be that as it may, in historical times it was a most lively popular festival, probably modelled on the Greek *Kronia* (*see* CRONUS). All business, public and private, was at a standstill; schools were closed, executions and military operations did not take place, slaves were temporarily free, feasting with and even waited on by their masters, and saying what they chose. All and sundry were greeted with *io Saturnalia*, and presents were freely exchanged, the traditional ones being wax candles and little clay dolls. Concerning these, the antiquaries had a quaint story that an old prophecy bade the earliest inhabitants of Latium send φῶτα to Saturn and heads to Pluto; that they interpreted this as meaning human sacrifices, but that Hercules (*q.v.*) advised them to use lights (the word ΦΩΣ means "light" or "man" according to accentuation) and not human "heads" (Macrob., *op. cit.*, i. 7, 31). Gambling with dice, generally forbidden, was allowed, a custom which is exactly paralleled from Nepal (Oldfield, *Sketches from Nepal*, ii. p. 353 *et seq.*). Saturnus himself was untied, presumably to come out and join in the fun.

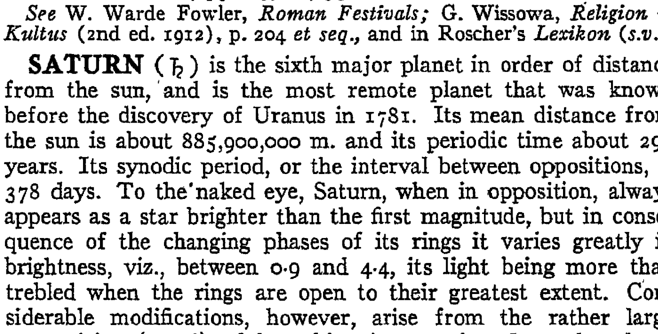
Saturni dies (Saturday) occurs first in Tibullus, I., 3, 18, *see* Colson, *The Week*, pp. 15, 16, 35.

See W. Warde Fowler, *Roman Festivals;* G. Wissowa, *Religion u. Kultus* (2nd ed. 1912), p. 204 *et seq.*, and in Roscher's *Lexikon* (*s.v.*).

SATURN (♄) is the sixth major planet in order of distance from the sun, and is the most remote planet that was known before the discovery of Uranus in 1781. Its mean distance from the sun is about 885,900,000 m. and its periodic time about 29½ years. Its synodic period, or the interval between oppositions, is 378 days. To the naked eye, Saturn, when in opposition, always appears as a star brighter than the first magnitude, but in consequence of the changing phases of its rings it varies greatly in brightness, viz., between 0·9 and 4·4, its light being more than trebled when the rings are open to their greatest extent. Considerable modifications, however, arise from the rather large eccentricity (0·056) of its orbit. As regards colour, the planet shines with a warm, yellowish light not unlike that of Arcturus.

The Globe.—In telescopic appearance the globe of Saturn exhibits strong resemblances to Jupiter. It is even more flattened at the poles, its polar and equatorial diameters being respectively about 67,000 and 75,000 m.; it is less bright near the margin than at the centre of the disc; and its surface is marked by dusky belts with light intermediate zones, but whereas these cloudlike bands are very conspicuous on Jupiter, they are usually feeble and ill-defined—partly in consequence of the planet's greater distance—in the case of Saturn.

The volume of Saturn is about 750 times that of the earth, but the periodic times of its satellites show that it exceeds the earth



FROM STEWART, "ASTRONOMY" (GINN & CO.)

PHASES OF SATURN'S RINGS

only about 95 times in mass. Its mean density, therefore, is but 0·13 of that of the earth, or over 0·7 times that of water.

Rotation.—Owing to the difficulty of detecting individual features of a sufficiently definite nature, the rotation of the planet has been observed only on comparatively rare occasions. The first determination was made in 1794 by the elder Herschel, who derived a rotation period of 10 h. 16 m. In Dec. 1876 a bright spot appeared near the equator which was observed by Asaph Hall, at Washington, for more than a month, and which showed a rotation in 10 h. 14 m. 24 s. In 1893 and 1894 A. S. Williams deduced from

observations of dark spots in the northern hemisphere mean rotation periods of 10 h. 14 m. 45 s. and 10 h. 15 m. 10 s. respectively, and in the same two years periods of 10 h. 12 m. 52 s. and 10 h. 12 m. 36 s. from a number of white equatorial spots. A further series of spots appeared in the planet's north temperate regions in 1903, and from the recorded observations of these objects Denning found a mean period of about 10 h. 38 m. It seems certain, therefore, that, as in the case of Jupiter, there are variations in the motions of the spots from year to year, and also that the rotation period is shorter near the equator than in higher latitudes.

Physical Condition.—It is further clear that what we see of Saturn is not a solid surface, but a layer of cloudlike or vaporous matter; the mean density of the globe is, indeed, less than that of any other major planet, and it is further to be noted that considerations based on the large ellipticity of the disc, which is greater than would be assumed by such a globe of anything like uniform density rotating with the angular velocity of Saturn, indicate that the larger part of the planet's mass must be strongly concentrated towards the centre.

The radiometric observations of Coblentz and Lampland suggest a surface temperature which, though considerably higher than can be accounted for by solar radiation, is a good deal lower than was formerly supposed to characterize the greater planets of the outer group. Conclusions based on such measurements, however, appear by themselves to be somewhat unreliable in consequence of the absorption of certain long-wave radiations by the earth's atmosphere, but a comparatively low temperature is supported by the theoretical work of Jeffreys. For further references to this interesting problem, and the observational evidences of considerable energy presented by the surface features of the great planets, *see* the articles PLANET and JUPITER.

There are several strong bands in the spectrum of Saturn, due to absorption in the planet's atmosphere. They are identical with those shown by the spectra of Jupiter, Uranus and Neptune, though of greater intensity than in the spectrum of the former and of less intensity than in those of the two last-mentioned planets. Their origin is still unknown.

The Rings.—But Saturn's most remarkable feature, and that which renders it unique, so far as our knowledge goes, is the magnificent system of rings by which it is surrounded. That Saturn differs in appearance from other bodies was seen at once by Galileo when he turned his little telescope towards it in 1610, but his instrument was not sufficiently powerful to show clearly what it was that he saw. He noticed that the planet had a small attendant on each side, and accordingly represented it as a triple body. But during the next few years the appendages dwindled and finally disappeared, greatly to his perplexity and chagrin, as he feared he must have been misled by some kind of illusion. When they subsequently reappeared they continued to present a difficult problem to the telescopic observers of the day—sometimes seeming like arms stretching out on each side of the central body, and sometimes like curved handles—and a number of curious drawings have come down to us which show how puzzled the observers were, but how near some of them came to the solution of the mystery. The true explanation was ultimately arrived at by Huyghens in 1655, but, wishing for further time to make sure of his solution and yet secure himself against the possible loss of priority in the discovery, he published the following series of letters:—aaaaaaa ccccc d eeeee g h iiiiiii llll mm nnnnnnnnn oooo pp q rr s ttttt uuuuu; which, when properly arranged, form the sentence:—*"Annulo cingitur, tenui, plano, nusquam cohaerente, ad eclipticam inclinato"* (It is girdled by a thin flat ring, nowhere touching, inclined to the ecliptic). These last few words explain the various appearances which so sorely puzzled the earlier observers with their imperfect instruments. The plane of the ring is inclined about 27° to the planet's orbit, and about 28° to the ecliptic, and keeps parallel to itself throughout the planet's revolution. There are accordingly two opposite portions of the orbit, viz., near longitudes 172° and 352°, where Saturn is in Leo and Aquarius respectively, at which the ring can be presented edgewise to the earth, and when this event happens (as it does either once or three times during each passage of the ring plane across the earth's orbit) the ring—owing to its thinness—disappears from view even in powerful instruments. At intermediate positions, viz., when the planet is in Taurus and Gemini and in Sagittarius, it appears opened out at an angle of 27°, and is then seen to project slightly beyond the polar diameter of the planet's globe.

The next important telescopic discovery as regards Saturn was the detection by G. D. Cassini, in 1675, of a black line or gap dividing the ring into two concentric rings. This is generally known as "Cassini's division." The ring exterior to this division is narrower and less bright than the inner ring, while the outer portion of the latter is the most brilliant part of the whole system. Within the second ring is yet another feature of great interest, viz., a third ring, commonly known as the Crape ring, of which the brightness is so feeble that it long escaped detection. It was first recorded by Galle, at Berlin, in 1838, but its existence was strangely forgotten till it was independently rediscovered, in 1850, by G. P. Bond at Harvard and W. R. Dawes in England. It can be readily traced with a comparatively small telescope as a dusky band where it crosses the planet's globe, but is not so easily seen in the portions projected against the dark sky. The three rings are often denoted by the letters A, B and C. From time to time other divisions besides that of Cassini have been reported, but they seem to have been merely partial and temporary, except that known as "Encke's division," in ring A, which is, perhaps, permanent, though probably not really a complete division. It usually appears as a pencil-like shading rather than a sharp black line, and sometimes merely as the boundary of the darker outer portion of the ring. The figures given by different authorities for the dimensions of the ring system differ somewhat, but the following are approximately correct:

Ring	Exterior diameter in miles	Breadth of ring in miles
A . . .	170,000	10,000
B . . .	145,000	16,000
C . . .	113,000	11,000

The breadth of the Cassini division is probably rather over 2,000 miles. The thickness of the rings is apparently between 20 and 40 m. only. It is noteworthy that all three are at least partly transparent; Saturn itself can be distinctly seen through the Crape ring, and on some recent photographs it also shows through the outer ring. Moreover, on Feb. 9, 1917, M. A. Ainslie, at Blackheath, and J. Knight, at Rye, observed that a seventh magnitude star (B.D. + 21° 1714), remained visible during its occultation by the outer ring, though Ainslie considered that it lost something like three-fourths of its light; it appeared to travel some distance along the Cassini division but did not pass behind ring B; and on March 14, 1920, during the occultation of Lalande 20,654 (Mag. 7·3), the star remained conspicuously visible in a 6-in. refractor at W. Reid's observatory, Rondebosch, South Africa, even when behind the brightest part of ring B, and despite the fact that, in consequence of the obliqueness of the line of sight, its light had to traverse a distance through the ring equal to eight times its real thickness.

The translucency of the ring system is also shown by the fact that it can be faintly seen against the sky as a narrow line of light on the occasions—sometimes extending over several weeks near the time of disappearance—when the plane of the rings passes between the sun and the earth. On this line of light two condensations are seen on each side of the planet, corresponding in position with the Cassini division and the Crape ring. They are apparently caused by the larger amount of sunlight transmitted at those places where the ring material is absent or relatively thin. The ring, as a whole, however, is sufficiently dense to cast a strong shadow, which is seen at such times as a narrow black band across the planet's equatorial regions.

The physical constitution of the rings is unlike that of any other object in the solar system. They are not formed of a continuous mass of solid or liquid matter, but of discrete particles

of unknown minuteness, probably widely separated in proportion to their individual volumes, yet so close as to appear continuous when viewed from the earth. This constitution was first divined by J. Cassini early in the 18th century. But, although the impossibility that a continuous ring could surround a planet without falling upon it was shown by Laplace, and must have been evident to all investigators in celestial mechanics, Cassini's explanation was forgotten until 1857. In that year James Clerk Maxwell, in an essay which was the first to gain the newly-founded Adams prize of the University of Cambridge, made an exhaustive mathematical investigation of the satellite constitution, showing that it alone could fulfil the conditions of stability. Although this demonstration placed the subject beyond doubt, it was of great interest when J. E. Keeler, at the Allegheny Observatory, proved this constitution by spectroscopic observation in 1895. He found, by measuring the velocity of different parts of the ring to or from the earth, that, as we pass from its outer to its inner regions, the velocity of revolution around the planet increases, each concentric portion having the speed belonging to a satellite revolving in a circular orbit at the same distance from the planet. The relative velocities of different parts of the system are beautifully shown by the slope of the lines in a spectrogram of Saturn made by V. M. Slipher of the Lowell Observatory.

Satellites.—Saturn is attended, so far as at present known, by nine satellites. A tenth (Themis) was announced by W. H. Pickering in 1905, but its actual existence has not been satisfactorily confirmed.

Details of the satellites are given in the following table:

Name	Distance in equatorial radii of Saturn (1=37·500 m.)	Period of revolution		Inclination of orbit to Saturn's orbit		Eccentricity	Stellar mag. at mean opposition	Discoverer	Date of discovery
		d	h	°					
Mimas	3·1	0	22·6	26	44·7	0·0190	12·1	W. Herschel	1789, Sept. 17
Enceladus	3·9	1	8·9	26	44·7	0·0001	11·6	W. Herschel	1789, Aug. 28
Tethys	4·9	1	21·3	26	44·7	0·0000	10·5	G. D. Cassini	1684, March
Dione	6·3	2	17·7	26	44·7	0·0020	10·7	G. D. Cassini	1684, March
Rhea	8·7	4	12·4	26	41·9	0·0009	10·0	G. D. Cassini	1672, Dec.
Titan	20·2	15	22·7	26	7·1	0·0289	8·3	Huyghens	1655, March
Hyperion	24·5	21	6·6	26	0·0	0·1043	13·0	Bond	1848, Sept. 16
Iapetus	58·9	79	7·9	16	18·1	0·0284	10·1 to 11·9	G. D. Cassini	1671, Oct.
Phoebe	214·2	550	10·6	174°.7		0·1659	14·5	W. H. Pickering	1898, Aug.

The diameters assigned by observers to the smaller and fainter satellites are necessarily very uncertain, but that of Titan is probably not far from 3,000 miles. The diameter of Phoebe is, perhaps, only about 150 miles.

The five inner satellites seem to form a class by themselves. Their orbits are nearly circular and their planes coincide exactly or very nearly with that of the ring system and the planet's equator. Thus, so far as the position of the planes of rotation and revolution are concerned, the system keeps together as if it were rigid. This results from the mutual attraction of the various bodies. A remarkable feature of this inner system is the near approach to commensurability in the periods of revolution. The period of Tethys is very nearly double that of Mimas, and the period of Dione about double that of Enceladus. The result of this near approach to commensurability is a wide libration in the longitudes of the satellites, having periods very long compared with the times of revolution.

Each of the four outer satellites has some special feature of interest. Titan is much the brightest of all; Hyperion is so small as to be visible only in a powerful telescope, and has a quite eccentric orbit; its time of revolution is almost commensurable with that of Titan, the ratio of the periods being 3 to 4, with the result that the major axis of the orbit of Hyperion has a retrograde motion of 18° 40′ annually, of such a character that the conjunction of the two satellites always occurs near the apocentre of the orbit, when the distance of the orbit from that of Titan is the greatest. This is among the most interesting phenomena of celestial mechanics. Iapetus has the peculiarity of always appearing brighter when seen to the west than to the east of the planet; this is explained by the supposition that, like our moon, this satellite always presents the same face to the central body.

Phoebe, the outermost satellite, is more than three and one-half times as remote from Saturn as Iapetus, and the circumstances of its discovery are interesting. In studying photographs of the neighbourhood of Saturn taken at Arequipa Observatory, Peru, Pickering found on each of three plates a very faint star which was missing on the other two. He concluded that these were the images of a satellite moving around the planet, which was then entering the Milky Way, where minute stars were so numerous that it was not easy to confirm the discovery. When Saturn began to emerge from the Milky Way no difficulty was found in relocating the object and proving that it was a ninth satellite. Its motion, however, was found to be retrograde or in a contrary direction to that of the other satellites. This difference of motion in a single system was, according to the knowledge of that time, a unique phenomenon, for although the satellite of Neptune and those of Uranus were known to have retrograde motions, they are the only satellites of those planets hitherto discovered. But more recently the eighth and ninth satellites of Jupiter have been found, and the motion of these, like that of Phoebe, is retrograde. (T. E. R. P.)

SATURNIAN METRE [Lat., *Saturnius, see* SATURN], a native Italian metre, used in some of the oldest known Latin compositions. It was in later times wholly displaced by Greek metres, and but few specimens survive. These are (1) inscriptions, notably some of the epitaphs of the Scipios, (2) fragments of Livius Andronicus's translation of the *Odyssey*, and of Naevius's *Bellum Punicum*, with a very few remnants of other authors. The following are specimens of this verse:

Dabunt malum Metelli/ Naevio poetae
Quamde mare saevom/ vis et quoi sunt magnae.

The scansion is very doubtful; on the whole it is more likely that it is accentual[1] than that it is quantitative. Some account of it will be found in Lindsay, *Early Latin Verse*, p. 9.

Nothing resembling the Saturnian exists in English; the example given by Macaulay ("The queen was in the parlour eating bread and honey") is not in the least like it.

SATURNINUS, LUCIUS APPULEIUS, Roman politician. Quaestor in 104 B.C., he superintended the importation of corn at Ostia, but was removed by the Senate, apparently without any charge against him being made, and so went over to the popular party. Tribune in 103, he made an arrangement with Marius for the allotment of 100 *iugera* of land to each of Marius' veterans. It was probably at this time also that he introduced his law on *maiestas* (treason), which seems to have been designed to increase the power of the tribunes. In 101 he was tried for violating the law of nations in connection with the embassy of Mithridates. The envoys had arrived with large sums of money to bribe the Senate, and Saturninus exposed the affair and insulted the ambassadors. He escaped by appealing to the people. He further

[1]On this theory, in its most probable form, the line has 3+2 accents, and usually consists of 7+6 syllables, as "quóius fórma virtútei parísuma fúit."

cultivated popularity by supporting the claims to citizenship of a freedman, Equitius, who posed as a son of Tiberius Gracchus (*q.v.*). Saturninus allied himself with C. Servilius Glaucia, and the two of them acted as Marius' political agents after his return from the war with the Cimbri. By bribery and murder Marius was elected consul for the sixth time in 100, Glaucia praetor and Saturninus tribune again. Saturninus then brought forward an extension of the African agrarian scheme, which included the distribution of the land north of the Po, taken from the Cimbri, among Marius' veterans, and the foundation of a number of new citizen colonies, to which Italians were to be admitted, a feature which caused a good deal of opposition. A further clause provided that every Senator should swear to observe it within five days of its becoming law. Metellus Numidicus, Saturninus' chief enemy, alone refused, and went into exile. The law was passed eventually after considerable disorder. At last Saturninus and Glaucia found themselves in danger of being disowned by Marius, and their only hope of safety lay in retaining office. In the elections at the end of 100 Saturninus was again elected tribune, and Glaucia stood for the consulship. During the voting their partisans beat C. Memmius, the senatorial candidate, to death. The Senate declared them public enemies, and called on Marius to take up arms against them. Saturninus was defeated in a battle in the forum, and took refuge in the Capitol (Dec. 10). Forced to surrender, he and Glaucia and their followers were imprisoned in the *Curia Hostilia,* and some of the opposite party tore off the roof and stoned them to death.

SATYRS, in Greek mythology, spirits half-man, half-beast. They are not mentioned in Homer; in a fragment of Hesiod they are called brothers of the mountain nymphs and Curetes, an idle and worthless race. They were a roguish but faint-hearted folk, lovers of music, wine and women, dancing with the nymphs or pursuing them, and striking terror into men. They had a special form of dance called *Sikinnis.* In early Attic art they were represented as grotesque men with horses' tails; later they approached the type of Pan (q.v.). A famous statue, supposed to be a copy of a work of Praxiteles, represents a graceful satyr leaning against a tree with a flute in his hand. In Attica there was a species of drama known as the satyric; it treated its themes in a half-comic manner and the chorus was composed of satyrs. Sophocles's *Ichneutai* and Euripides's *Cyclops* are the only extant examples. In Italy, the satyrs are often identified with the fauni (*see* FAUNUS).

In the Authorized Version of Isa. xiii. 21; xxxiv. 14 the word "satyr" is used to render the Hebrew *sĕ'īrīm,* "hairy ones." A kind of demon or supernatural being known to Hebrew folk-lore as inhabiting waste places is meant; a practice of sacrificing to the *sĕ'īrīm* is alluded to in Lev. xvii. 7, where the English version has "devils." They correspond to the "shaggy demon of the mountain-pass" (*azabb al-'akaba*) of old Arab superstition.

See also SILENUS. For similar modern Greek beliefs, *see* Lawson, *Modern Greek Folk-lore,* p. 190.

SAUCE, a flavouring or seasoning for food, usually in a liquid or semi-liquid state, either served separately or mixed with the dish. The preparation of suitable sauces is one of the essentials of good cookery. The word comes through the Fr. from the Lat. *salsa,* salted or pickled food (*salire,* to season or sprinkle with *sal,* salt). The colloquial use of "saucy," impertinent, "cheeky" is an obvious transference from the tartness or pungency of a sauce.

Hot Sauces.—These may be divided into *White* and *Brown,* and from them many hundreds of sauces are made. Variations from a plain white sauce are egg sauce, onion sauce, anchovy sauce, parsley sauce, caper sauce, oyster sauce, celery sauce, etc. A blending of fat and flour, known in the culinary world as a *roux,* is the foundation of nearly every sauce. The fats used may be butter, oils, clarified fat, a blend of lard and butter, or margarine, or dripping. The fat is first melted and sufficient flour is stirred into it to absorb it; equal quantities of fat and flour are usual. Liquids for white sauces may be water, milk and water, milk, white stock, milk and stock. Cream may be added if liked, also beaten eggs and any flavouring such as sherry, vanilla, vinegar, lemon juice. Brown stock, water, or stock and water, are the liquids used for brown and fawn sauces. Lumpy sauces are caused by insufficient stirring which causes unequal bursting and thickening of the starch grains in the flour. Sauces must boil for 8 to 10 minutes. Espagnole, Béchamel and Velouté are white sauces used as a foundation in many variations.

Cold Sauces.—(*1*) *The Mayonnaise Class.* A simple mayonnaise is made from raw yolk of egg, salad oil, tarragon and white wine vinegars, mustard, pepper and salt. One yolk of egg will blend with as much as ½pt. oil if the oil is stirred in very gradually, drop by drop, to the yolk: the vinegar can be added from time to time as the mixture gets thick and the quantity can be left to the taste of the cook. A good mayonnaise should not taste too acid or too oily. Additions of chopped capers or gherkins to this make Tartare sauce.

2. Chaudfroid Sauces, for coating meat, poultry, fish. These may be brown, fawn, white, red, green, the foundations being a good brown or white sauce, tomato sauce, cucumber sauce. To these sauces are added aspic jelly, gelatine and a little cream.

Miscellaneous Sauces.—(a) those made from purées, some of which are thickened with cornflour, *i.e.* tomato, cucumber, spinach, apple, celery, (b) custard sauces made from eggs and milk and flavoured with vanilla, lemon or wine, *i.e.,* sherry sauce, (c) those made from syrups, *i.e.,* jam, lemon, marmalade, (d) mint, horseradish. (E. G. C.)

SAUGERTIES, a village of Ulster county, New York, U.S.A., on the west bank of the Hudson river, at the mouth of the Esopus, 100 m. N. of New York city, near the base of the Catskill mountains. It is on Federal highway 9 W. and is served by the West Shore railroad and river steamers. Pop. 1930, 4,060 Federal census. It is in the midst of picturesque scenery and there are many summer homes along the Hudson and elsewhere in the vicinity. The village of Woodstock (incorporated 1787) with its colony of artists and summer art school is 10 m. W., and 4 m. S. of Woodstock is the Ashokan reservoir. Saugerties has several paper and paper-products mills, limestone and bluestone quarries, brickyards and other industries. The village was settled about 1710 by Germans, and several houses date from the 18th century. It was incorporated in 1831.

SAUGOR or SAGAR, so named after its beautiful lake, a town and district of British India in the Jubbulpur division of the Central Provinces. The town, in a picturesque situation on a spur of the Vindhyan hills about 1,700 feet above sea level, has a station of the Indian Midland section of the G.I.P. Railway. Population (1921) 39,319. It has ceased to be a growing place, though it is still fourth in importance in the province. The town is handsomely built and the cantonment well wooded. It has no factories and its old industries, which included the manufacture of gold and silver ornaments, are not very flourishing. There is an old Mahratta fort, now used as a police school, which was held for several months by the Europeans in the Mutiny until relieved by Sir Hugh Rose.

The district of Saugor has an area of 3,962 square miles. It is an extensive, and in parts fairly level, plain, broken in places by low stony hills of Vindhyan sandstone. It is traversed by numerous streams, of which the Sunar, Beas, Dhasan and Bina are the principal, flowing in a central direction and being affluents of the Ganges. In the southern and central parts the soil is black, formed by decaying trap. In the north and east it is reddish-brown alluvium. The population in 1921 was 528,380, or some 60,000 less than in 1891, but it is likely to recover if seasons are good.

The district contains five small towns and 1,830 villages. The chief land-holding classes are Brahmins, Dangis, Lodhis and Bundela Rajputs. Mohammedans are only 5% of the population. Government forests cover 750 sq.m. but are not of great value. There is good iron ore in the Shahgarh tract smelted in small

furnaces and some fine sandstone quarries.

SAUGUS, a town of Essex county, Massachusetts, U.S.A., adjoining Lynn on the west. It is served by the Boston and Maine railroad. Pop. (1920) 10,874 (23% foreign-born white); 1930 Federal census 14,700. Saugus is now primarily a residential town, but in early times it was important industrially. It was one of the first New England towns to engage in the manufacture of shoes and woollen goods, and was the site of the first iron works, where the die for the Pine-Tree shilling was cast. Settlement dates from 1629. The town was incorporated in 1815.

SAUJBULAQ (sowj-boo-lahk′), chief town of that part of the Persian province of Azerbaijan south of Lake Urmia. Ethnographically, the district forms part of Persian Kurdistan. The town stands in a remarkably fertile valley, in 36° 45′ N., and 45° 47′ E., at an elevation of 4,272 ft. The population, till the outbreak of the World War, was about 7,000, chiefly of settled Kurds of the Mukri tribe of which it may be regarded as the local capital. The town is connected with Tabriz by a road passable for motors, via Urmia, Khoi and Julfa.

There are many more localities named Saujbulaq (Turkish, meaning "cold stream," or "cold spring") in Persia, the most notable, after the above-mentioned Kurdish city, being a district of the province of Tehran, with many villages.

SAUK and **FOX.** These two closely related Algonkin tribes were encountered west of Lake Michigan by the French in the second half of the 17th century. The Sauk (or Sac) had been driven there from Michigan by Iroquoian and Algonkin foes not long before; the Fox, probably somewhat earlier. The friendship of the French for these foes rendered the Fox, and finally the Sauk, enemies of the French. They were the only Algonkin so to align themselves; and in the end withdrew from Wisconsin to Iowa, where they found shelter in territory of the Siouan tribe of that name. This change removed them from the timber to the prairies, and their culture began to be characteristic of the open spaces. They remained restless and aggressive, and in 1832, with the Kickapoo, engaged in the Black Hawk war. The two tribes probably never numbered much more than 3,000 each, and were often considerably reduced by warfare. A total of 1,000 remain on reservations in Iowa, Kansas and Oklahoma.

SAUL, son of Kish, a Benjamite, was the first king of Israel. He began to reign *c.* 1025 B.C. The traditions as to his history are closely interwoven with those concerning Samuel and David. Various views may be taken of these records, among the most dramatic in sacred literature but, by scholars, it is generally recognized that the stories of 1 Samuel preserve two different traditions about the rise of the monarchy in Israel. In each there is an account of Saul's election; each relates that he was anointed by Samuel and records his rejection. It is probable that two distinct continuous histories have been combined in the existing text of Samuel. According to the later of the two traditions the elders of Israel, seeing that the sons of Samuel, who are destined to succeed him, are corrupt, demand that he shall make them a king "to judge them like all the nations." Samuel is displeased, but Yahweh reluctantly—for such a request was a grave affront to the deity, the true king of Israel—bids him concede the demand. The seer points out to the people that a king will oppress them, but fails to dissuade them (1 Samuel viii.). He summons a solemn assembly at Mizpah, and, once more reminding them of their folly, chooses Saul, by lot under Yahweh's direction (x. 17–24). In an elaborate sermon (xii.), he succeeds in convincing the people that their action has been sinful. And hardly has Saul seated himself upon the throne when Yahweh rejects him, and bids Samuel anoint David to succeed him in due time (xvi. 1–13). *See* SAMUEL.

The earlier tradition, which is distinctly more primitive in its religious ideas, contributes other sidelights on the matter. Samuel, to whom Saul comes seeking the seer's help in the finding of some lost asses, is previously warned by Yahweh that the suppliant is the divinely chosen saviour who is to deliver Israel from Philistine oppression. With whole-hearted enthusiasm Samuel anoints Saul to be "prince over Yahweh's inheritance" (ix.–x. 1). Saul and his son Jonathan achieve notable victories over the Philistines (xiii.). According to this tradition Saul is a God-given saviour, like the heroes in Judges, who rescues his people from the grievous domination of the Philistines. An appropriate introduction to this narrative is missing from 1 Samuel, but the introduction to the story of Jephthah (Judges x. 6–16)—to which what follows is certainly not the obvious sequel—would very well fit it. The suggestion has therefore been made that possibly according to an old tradition Saul was the immediate successor of Jephthah (*cf. Cambridge Ancient History,* vol. ii. p. 371 *seq.*).

Though the reign of Saul was marked by considerable successes he was hampered by friction within as well as by foes without. Comparatively early his relations with Samuel seem to have become strained, and his declining years were embittered by the growing importance of his rival, David. Finally he fell a victim to his ancient enemies, the Philistines, who inflicted a heavy defeat on Israel in the battle of Mount Gilboa, where his sons were slain, and he himself perished. Here, again, we have two distinct accounts. According to one, being "greatly distressed by reason of the archers," he implored his armour-bearer to kill him, that he might not be slain by uncircumcised Philistines, and when his armour-bearer refused fell upon his own sword (1 Samuel xxxi. 1–7). The other story (2 Samuel i. 1–10), represents him as making a similar request to an Amalekite camp-follower, who, unlike the armour-bearer, complies. It is possible that this is a fiction on the part of the Amalekite, though the context hardly suggests such a view.

According to one estimate of the documents, the character of Saul was depreciated by Judaean historians anxious to exalt David and by anti-monarchists whose ideal was Samuel. Others have found in the narrative an ethical significance of perpetual value. However, Saul played a considerable part in the freeing of Israel from the Philistine yoke. Though his reign ended in the gloom of tragedy he achieved notable successes on the battle-field, and was a greater king than the existing narratives would lead us to suppose. This is borne out by the ascription to him of important victories (*cf.* 1 Samuel xiv. 42–51) and even more by the ancient lament from the "book of Jashar" (2 Samuel i. 19–27), which paints the fallen king as "mighty," a warrior whose "sword returned not empty," "swifter than an eagle," "stronger than a lion," who brought good spoil to his people, and whose death was to the Philistines a source of exultation. That he maintained his position despite the popularity of David, and that his kingdom endured for a time after his death even with a weakling like his son Ishbosheth as its nominal head, point in the same direction. In short, we may discern in the Scriptural narratives the figure of a brave, impulsive, superstitious man, whose contribution towards the building up of the kingdom has been underestimated.

(W. L. W.)

SAULT SAINTE MARIE (sōō-sānt-mạ-rē′), a city of Michigan, U.S.A., at the east end of the Upper Peninsula, on St. Mary's river, the outlet from Lake Superior into Lake Huron; a port of entry and the county seat of Chippewa county. It is on Federal highway 2 and is the northern terminus of the Dixie highway; and is served by the Canadian Pacific, the Duluth, South Shore and Atlantic and the Soo Line railways, and lake steamers. A railway bridge and ferries connect it with the Canadian town of the same name in Ontario on the north side of the river. The population was 12,096 in 1920 (31% foreign-born white, chiefly from Canada) and was 13,755 in 1930 by Federal census. The river here drops ("leaps") 20 ft. in less than a mile, which explains the name given to the falls by the early French missionaries. The two canals, with their five great locks (four on the American side, one on the Canadian), are the greatest ship highway in the world. An average of 100 ships a day pass through during the navigation season of eight months, and the total traffic in 1928 amounted to 86,992,927 tons, valued at $1,183,123,800. The Davis and the Sabin locks (1,350 ft. long and 80 ft. wide) are the longest in the world. Two large hydro-electric plants generate current from the falls. The city is the centre of a summer-resort region abounding in beautiful scenery, good fishing and hunting, with a climate especially favourable to cases of hay fever. It has a considerable lake traffic (760,926 tons in

1925), chiefly in coal and limestone; is a shipping point for farm, forest and dairy products by rail; and has various manufacturing industries, with an output in 1927 valued at $8,950,416. Since 1917 it has had a commission-manager form of government.

Sault Sainte Marie is the oldest settlement in Michigan. The place was a favourite fishing-ground of the Chippewa Indians. It was visited in succession by Étienne Brule (some time between 1611 and 1623), Jean Nicollet (1634), Jogues and Rambault, who gave it its name (1641), Radisson and Groseilliers (1658), and in 1668 Father Marquette founded a mission here. In 1671 the governor-general of New France called a great council of the Indians at this spot, and in the name of the king of France took formal possession of all the country south to the Gulf of Mexico and west to the Pacific. The British flag flew over the American Sault from 1762 until June 15, 1820, when Governor Lewis Cass raised the Stars and Stripes. The first Ft. Brady was built in 1822 and was occupied until 1893, when the post was rebuilt on its present site. The village was incorporated in 1879 and was chartered as a city in 1887. St. Mary's river was navigated by the canoes and bateaux of the Indians and early *voyageurs,* who made a portage around the falls. The North West Fur company built a lock on the Canadian side of the river in 1797–98. The state lock and canal (later widened and deepened by the Federal government) were opened in 1855. The Weitzel lock (515 ft. long) was completed in 1881; the Canadian (900 ft.) in 1895; the Poe (800 ft.) in 1896; the Davis in 1914; and the Sabin in 1919. Previously to 1929 the maximum traffic passing "the Soo" in a year was 91,888,219 net tons in 1916.

SAUMAREZ, JAMES SAUMAREZ [or Sausmarez], Baron de (1757–1836), English admiral, was born at St. Peter Port, Guernsey, on March 11, 1757. He entered the navy as midshipman at the age of thirteen. For his bravery at the attack of Charleston in 1776, on board the "Bristol" he was raised to the rank of lieutenant, and he was promoted commander for his gallant services off the Dogger Bank, Aug. 5, 1781, when he was wounded. In command of the "Russell" (70), he contributed to Rodney's victory over De Grasse (April 12, 1782). For the capture of "La Réunion," a French frigate, in 1793, he was knighted. He took part in the defeat of the French fleet off Lorient, (June 22), distinguished himself in the battle of Cape St. Vincent in Feb. 1797, and was present at the blockade of Cadiz (Feb. 1797–April 1798), and at the battle of the Nile, where he was wounded. On his return from Egypt he received the command of the "Caesar" (84), with orders to watch the French fleet off Brest during the winters of 1799 and 1800. Between July 6 and 12, 1801, he routed a superior combined force of French and Spanish ships at Algeciras. On the outbreak of the war with Russia in 1809 he was given command of the Baltic fleet. He held it during the wars preceding the fall of Napoleon, and his tact was conspicuously shown towards the government of Sweden at the crisis of the invasion of Russia. At the peace of 1814 he attained the rank of admiral; Charles XIII. (Bernadotte) bestowed on him the grand cross of the military order of the Sword. He was raised to the peerage in 1831, and died at Guernsey on Oct. 9, 1836.

See *Memoirs of Admiral Lord de Saumarez,* by Sir John Ross (2 vols., 1838).

SAUMUR, a town of western France, capital of an arrondissement in the department of Maine-et-Loire, 28 m. S.E. of Angers on the railway to Tours. Pop. (1926) 13,776. The Saumur caves along the Loire and on both sides of the valley of the Thouet must have been occupied at a very remote period. The Tour du Tronc (9th century), the old stronghold of Saumur, served as a place of refuge for the inhabitants of the surrounding district during foreign invasions (whence perhaps the name Saumur, from *Salons Murus*) and became the nucleus of a monastery built by monks from St. Florent le Vieil. On the same site rose the castle of Saumur two hundred years later. The town fell into the hands of Foulques Nerra, duke of Anjou, in 1025, and passed in the 13th century into the possession of the kings of France. After the Reformation the town became the metropolis of Protestantism in France and the seat of a theological seminary which, as opposed to that of Sedan, represented the more liberal side of French Protestantism (Cameron, Amyraut, etc.). In 1623 the fortifications were dismantled; and the revocation of the edict of Nantes reduced the population by more than one half. In June 1793, the town was occupied by the Vendéens, against whom it soon afterwards became a base of operations for the republican army.

Saumur stands on the left bank of the Loire, which here receives the Thouet, and on an island in the river. A large metal bridge connects the Tours-Angers railway with that of Montreuil-Bellay, by which Saumur communicates with Poitiers and Niort. Two stone bridges (764 and 905 ft. long) unite the town on the island with the two banks of the river. The church of St. Pierre, of the 12th century, has a 17th-century façade and a Renaissance nave; and Notre-Dame of Nantilly has a remarkable façade, a doorway and choir of the 12th century, and a nave of the 11th. St. Jean is a 12th-century building in the purest Gothic style of Anjou. St. Nicolas-du-Chardonnet, 12th century Gothic, has a fine modern spire. The *hôtel de ville* is a 16th century building and the town has many houses of the 15th, 16th and 17th centuries, notably that known as the Maison de la Reine Cécile (15th century), built by René, duke of Anjou. The castle was built between the 11th century and the 13th, and remodelled in the 16th. There is also an interesting almshouse, with its chambers in part dug out in the rock. The famous cavalry school of Saumur was founded in 1768 and was used for the special training of young officers appointed to cavalry regiments on leaving the cadet school of St. Cyr. Saumur is the seat of a sub-prefect, and of a tribunal of commerce, a chamber of commerce, and a horticultural garden, with a school of vines. Saumur prepares and carries on a large trade in the sparkling white wines made in the neighbourhood, as well as in brandy, and it manufactures enamels and rosaries and carries on liqueur-distilling.

SAUNDERSON or Sanderson, **NICHOLAS** (1682–1739), English mathematician, was born at Thurlstone, Yorkshire, in Jan. 1682. When about a year old he lost his sight through smallpox; but this did not prevent him from acquiring a knowledge of Latin and Greek, and studying mathematics. In 1707 he began lecturing at Cambridge on the principles of the Newtonian philosophy, and in Nov. 1711 he succeeded William Whiston, the Lucasian professor of mathematics in Cambridge. He was admitted F.R.S. in 1736 and died on April 19, 1739.

Saunderson devised a calculating machine or abacus, by which he could perform arithmetical and algebraical operations by the sense of touch; this method is sometimes termed his *palpable arithmetic,* an account of which is given in his elaborate *Elements of Algebra* (2 vols., Cambridge, 1740).

SAUROPSIDA, a term introduced by T. H. Huxley to designate a province of the Vertebrata formed by the union of the Aves with the Reptilia. Ichthyopsida, including the Pisces and Amphibia, was used by Huxley as an antithesis. Both terms and the idea which underlay them are obsolete.

SAUSAGES are mentioned by Athenaeus in the *Deipnosophists,* A.D. 228, the oldest cookery book that has come down to us; he says "Epicharmus mentions sausages, calling them *oryae,* a name by which he even entitles one of his plays, the *Orya*"; this was written about 500 B.C. Again: "Aristophanes says in the *Clouds* (423 B.C.): 'Let them make sausages of me and serve me up to the students.'" Charles Lamb in the *Essays of Elia* (1823) mentions them "as the savouriest part, you may believe, of the entertainment" given "at the annual feast of chimney-sweepers . . . held in Smithfield, upon the yearly return of the fair of St. Bartholomew"; and Professor George Saintsbury in 1922 laments the disappearance of "that most admirable variety the Oxford Sausage" and the decadence of others.

Technically a sausage is a mixture of meat minced, seasoned, and stuffed into casings which originally consisted of the intestines of hog, sheep or cattle, those of sheep being the most delicate or tender; they are properly cleansed, soaked in lime water or lye, then washed again, and salted or soaked in brine, by specialized firms of cleaners who carry on the business in the vicinity of the abattoirs. Home-produced supplies of casings do not, however, form more than 10 per cent of total supplies of Great Britain, the bulk being received from the United States.

Manufactured casings are sold by the bundle of 100 yards, home-produced supplies fetching from 7/6d. to 10/– per bundle. As a result of research in the manufacture of synthetic sausage skins, which was begun in 1916, the American Chemical Society in 1928 announced the invention of a sausage casing made from cellulose, which may be manufactured in any size, is more quickly filled, and has none of the imperfections that are said to spoil the animal casings.

Dr. Tibbles in "Foods, their origin, composition and manufacture" (1912), remarks, "It is said that horse-flesh is sometimes used in the manufacture of German sausages," and adds that it is difficult to detect the various kinds of flesh except by microscopical and chemical examinations, as the muscular fibres are much alike. Bread and other materials are also used, and in the *Report on the Pork and Bacon Trades in England and Wales* issued by the British Ministry of Agriculture and Fisheries early in 1928 the suggestion is put forward that "from the point of view of the consumer, it is a disadvantage not to know the composition of the food which he buys. Trade organizations might, therefore, consider whether it would not be in their interests to adopt grade specifications for pork sausages according to the proportions of pork and other materials which they contain." There are considerably over one hundred varieties, some of which are further varied in different districts.

Some Well-known Varieties.—*Boudins* or *boudins noir* or *black puddings* as they are called in England, are made in some parts of Scotland of hog's blood, shredded suet, dried oatmeal and minced onions with plenty of pepper and salt; as Hudibras says:

"Fat Black Puddings—proper food
For warriors who delight in blood,"

but their seasoning varies in different localities. In England for example caraway and coriander are used in Cheshire, but the Shropshire variety has none of the former and very little of the latter; in Staffordshire the seasoning consists of equal quantities of salt, pepper, marjoram, and pimento with twice as much thyme; in Yorkshire twice as much marjoram and thyme as pepper and salt, also a little savoury and lemon thyme may be used; whilst the Stretford variety is highly seasoned with equal proportions of salt, pepper, marjoram mint and thyme. In France beetroot leaves and garlic are sometimes used; in Spain fennel may be added; in Germany thyme and marjoram.

In some parts of France it is the custom to eat black puddings on Christmas Eve after returning from midnight mass. They are always boiled directly they are made and are then kept in a cool place; when served they may be either boiled up again or grilled. In Flanders they are accompanied by a dish of baked apples.

In addition to Scottish black puddings there are Scottish white puddings made of good beef-suet minced and mixed with a third of its weight in highly toasted oatmeal, seasoned with salt and pepper stuffed into skins and boiled. Liver puddings are made in the same way with the addition of one-fourth the quantity of parboiled liver grated, and some shredded onions.

The French *Boudins Blancs* are most superior. They are made of the white parts of raw chicken finely minced, yolk of eggs, onions, breadcrumbs, salt and spices mixed with cream or milk, stuffed into skins and boiled in milk and water; when served they are grilled. Other French *boudins* are made of game, fish, etc.

Sausages are technically described as "dry" or "fresh and wet"; they may be made of raw or cooked material, and the "dry" varieties may be boiled, smoked, pickled or air-dried.

Italy and Germany vie with each other in the varieties they produce. *Salami*, a popular Italian, Hungarian and German sausage, is generally made of pork, beef, bacon, highly seasoned, coloured with red wine, and finally pickled and dried; *Bologna*, a large sausage made of finely chopped bacon, veal and pork, is sold ready to serve without further preparation; and *Mortadella* made at Florence and Bologna from the flesh of pigs which feed on the chestnuts and acorns in the surrounding forests, and seasoned with wine, garlic and spices, are all popular as hors d'oeuvre.

Frankfurt and Vienna sausages are about the length of a finger and are composed of raw lean pork and beef, well smoked; they should be eaten hot; if kept too long they get dry and are liable to turn sour. They have become increasingly popular.

Bockwürst is a small sausage at one time served with Bock beer.

The Spanish *Chorizos* is similar to the Frankfurt but very highly seasoned and air-dried.

Polony is a corruption of Bologna whose sausages it resembles. Sheffield is more celebrated for them than any other town in England.

Saveloys (Fr. *andouilles*) are short thick sausages originally made from pigs' brains and called "cervelas" of which word saveloy is a corruption; they are now made of cooked pork highly seasoned, stuffed into red skins and sold ready to eat; some varieties are smoked.

Oxford sausages, "much herbed, skinless, are moulded into sausage shape only just before cooking."

Hamburg is not only famous for its sausages but has also a special reputation for casings. "The running intestine is used for *Bolognas*, the middle for ham and chicken sausage and for *Leberwürst* or liver sausage and the larger for the full-sized German sausage.

For sausage poisoning *see* BOTULISM. (F. WH.)

The United States.—Sausage making is an important part of the meat industry in the United States. Figures published by the U.S. Department of Agriculture Bureau of Animal Industry indicate that during the Government fiscal year ending June 30, 1928, the amount of sausage chopped in establishments operating under Federal inspection amounted to 779,983,976 lb. This total compares with 679,314,965 lb. for 1923, 624,826,613 lb. for 1918 and 531,626,284 lb. for 1913, definite indication that the sausage industry in the United States is showing substantial growth. In addition to the quantities of sausage made in establishments operating under Federal inspection, large quantities are made by concerns doing an intrastate business, the maintenance of Federal inspection in such establishments not being required.

More than 100 varieties of sausage are made and sold in the United States. These may be divided into two main classes, "domestic" and "dry." Domestic sausage includes such well-known varieties as pork sausage, frankfurters, Bologna, head cheese, liver sausage, blood sausage, blood and tongue sausage and luncheon specialities. Dry sausage includes cervelat, salami, frisses, Genoa, peperoni, mortadella, capicolli, farmer, Holsteiner, Goteborg and chorizos. (R. H. GI.)

SAUSSURE, HORACE BENEDICT DE (1740–1799), Swiss physicist and Alpine traveller, was born at Geneva on Feb. 17, 1740. From 1762 to 1786 he was professor of philosophy at the academy of Geneva. He became F.R.S. in 1768, and in 1772 founded the *Société pour l'Avancement des Arts* at Geneva. His health began to fail in 1791, but he was able to complete his great work in 1796. He died on Jan. 22, 1799.

His early devotion to botanical studies led him to undertake journeys among the Alps, and from 1773 onwards he devoted his attention to the geology and physics of that great chain. He applied chemistry and physics to his studies of the geology and meteorology of the district. He examined the strata, nature of the rocks, the fossils and minerals. De Saussure designed a number of new instruments, notably his hair hygrometer with which he examined atmospheric conditions; he also made observations on the temperature of the earth and of deep water. These observations he published in *Essai sur l'hygometrie* (1783).

Among his most famous ascents were Mont Blanc (1787), Col du Géant (1788), Crammont (1784, 1788), St. Theodule pass to Zermatt (1789) Klein Matterhorn (1792).

The descriptions of seven of his Alpine journeys were published as *Voyages dans les Alpes* (4 quarto vols. 1779–96 and 8 octavo vols. 1780–96). The non-scientific portions of the work were first published in 1834, and have often been republished, under the title of *Partie pittoresque des ouvrages de M. de Saussure.*

See Lives by J. Senebier (Geneva, 1801), by Cuvier in the *Biographie universelle,* and by Candolle in *Décade philosophique,* No. xv. (trans. in the *Philosophical Magazine,* iv. p. 96); articles by E. Naville in the *Bibliothèque universelle* (March, April, May 1883), and chaps. v.–viii. of Ch. Durier's *Le Mont-Blanc* (various editions between 1877 and 1897).

SAUTERNES are white wines made in the vineyards of Sauternes and of the adjoining parishes of Bommes, Barsac, Preignac and Fargues in France. In all these parishes, which form the Sauternes district, the soil and subsoil are entirely different from the soil and subsoil of the Graves district, which it adjoins. Entirely different species of grapes are grown in the Sauternes district, species particularly well suited to the soil which produces a naturally sweet wine of unsurpassed excellence. The sweetness of Sauternes is the sweetness of the grape which is retained without the fermentation having been checked by added brandy, as is the case with sweet "fortified" wines.

The finest estate of the Sauternes district, the one which produces by far the finest Sauternes wine and usually also a far greater quantity than any other, is Château Yquem. The wines of Yquem possess both freshness and richness, a combination which is as admirable in a wine as it is rare; they have body, bouquet, breed, and, when of a good vintage, they will not only last but improve for a considerable time. The other Sauternes vineyards which produce the finest wines are those of the following châteaux: La Tour Blanche, Peyraguey, Vigneau, Rabaut, in the parish of Bommes; Suduiraut and Rieussec in the parish of Preignac; Coutet and Climens in the parish of Barsac; Guiraud and Filhot, in the parish of Sauternes.

Although part of the Sauternes district, the parish of Barsac produces wines which are quite distinctive, possessing a characteristic bouquet, and not being quite so sweet as the majority of Sauternes wines, but distinctly richer than Graves. (*See* WINE.)

(A. L. S.)

SAVAGE, RICHARD (d. 1743), English poet, was born about 1697, probably of humble parentage. A romantic account of his origin and early life, for which he at any rate supplied the material, appeared in Curll's *Poetical Register* in 1719. On this and other information provided by Savage, Samuel Johnson founded his *Life of Savage*, one of the most elaborate of the *Lives*. It was printed anonymously in 1744, and has made the poet the object of an interest which would be hardly justified by his writings. In 1698 Charles Gerrard, 2nd earl of Macclesfield, obtained a divorce from his wife, Anna, daughter of Sir Richard Mason, who shortly afterwards married Colonel Henry Brett. Lady Macclesfield had two children by Richard Savage, 4th earl Rivers, the second of whom was born at Fox Court, Holborn, on the 16th of January 1697, and christened two days later at St. Andrews, Holborn, as Richard Smith. Six months later the child was placed with Anne Portlock in Covent Garden; nothing more is positively known of him.

In 1718 Richard Savage claimed to be this child. His statements were suspicious, and Mrs. Brett always maintained that he was an impostor. The matter was thoroughly investigated for the first time by W. Moy Thomas, who published the results of his researches in *Notes and Queries* (second series, vol. vi., 1858). Savage, impostor, or not, blackmailed Mrs. Brett and her family with some success, for after the publication of *The Bastard* (1728) her nephew, John Brownlow, Viscount Tyrconnel, purchased his silence by taking him into his house and allowing him a pension of £200 a year. Savage wrote two successful plays: *Love in a Veil* (1718), adapted from the Spanish, and *Sir Thomas Overbury* (1724). His *Miscellaneous Poems* were published by subscription in 1726. In 1727 he was arrested for the murder of James Sinclair in a drunken quarrel, and only escaped the death penalty by the intercession of Frances, countess of Hertford (d. 1754).

Savage was at his best as a satirist, and in *The Author to be Let* he published a quantity of scandal about his fellow-scribblers. Proud as he was, he was servile enough to supply Pope with petty gossip about the authors attacked in the *Dunciad*. His most considerable poem, *The Wanderer* (1729), shows the influence of Thomson's *Seasons*, part of which had already appeared. Savage tried without success to obtain patronage from Walpole, and hoped in vain to be made poet-laureate. In 1732 Queen Caroline settled on him a pension of £50 a year. Meanwhile he had quarrelled with Lord Tyrconnel, and at the queen's death was reduced to absolute poverty. Pope had been the most faithful of his friends, and had made him a small regular allowance. With others he now raised money to send him out of reach of his creditors. Savage went to Swansea, but he resented bitterly the conditions imposed by his patrons, and removed to Bristol, where he was imprisoned for debt. All his friends had ceased to help him except Pope, and in 1743 he, too, wrote to break off the connection. Savage died in prison Aug. 1, 1743.

See Johnson's *Life of Savage*, and *Notes and Queries* as already quoted. He is the subject of a novel, *Richard Savage* (1842), by Charles Whitehead, illustrated by John Leech. *Richard Savage*, a play in four acts by J. M. Barrie and H. B. Marriott-Watson, was presented at an afternoon performance at the Criterion theatre, London, in 1891. The dramatists took considerable liberties with the facts of Savage's career. *See* also S. V. Makower, *Richard Savage, a Mystery in Biography* (1909).

SAVAGE ISLAND (NIUE): *see* PACIFIC ISLANDS.

SAVANNA or **SAVANNAH,** originally a meadow land or large, grassy, treeless tract, but now also including level areas with tall grasses and isolated clumps of trees, as in Nigeria, where the more appropriate name would be *park savanna*. It has also been commonly applied to the grassy plains south of the centre of North America, and is here the equivalent of prairie (*q.v.*).

SAVANNAH, a city of south-eastern Georgia, U.S.A., on the Savannah river, 18 m. from the Atlantic ocean; a port of entry and the county seat of Chatham county. It is on Federal highways 17 and 80; has a municipal airport; and is served by the Atlantic Coast Line, the Central of Georgia, the Savannah and Atlanta, the Seaboard Air Line and the Southern railways, and by steamship lines operating to both American coasts and to foreign ports. Pop. 83,252 in 1920 (47% negroes); and 85,024 in 1930.

The city occupies 7.4 sq.m. on a plateau 42 ft. above the river. It has retained and extended the original ground plan (designed by Oglethorpe) of broad, straight streets, interspersed at frequent and regular intervals with grassy squares and parks, which now cover altogether 898 acres. Many dwellings of colonial architecture and buildings of historic interest still remain; there are numerous statues and monuments to local and national heroes; and charm is added by thousands of shade trees and many sub-tropical plants. A granite seat marks the spot where Oglethorpe first pitched his tent. Gen. Nathanael Greene is buried under a monument erected to his memory in 1829. Christ church, now occupying its third building (erected 1838), was organized by George Whitefield in 1740, and its third rector was John Wesley, who established here the first Protestant Sunday-school in America. The First African Baptist church dates its history from 1788. Ten miles south of Savannah is Bethesda, the oldest orphan asylum in the United States, founded by Whitefield in 1740. "The Hermitage," 5 m. N., is a 500 ac. plantation on the river, settled in 1783, with many of the slave huts and other ante-bellum buildings still standing. "Wormsloe," at the south end of Isle of Hope, is occupied by lineal descendants of Capt. Noble Jones, to whom it was originally granted by George II. At "Mulberry Grove," the estate given by Congress to Gen. Greene, Eli Whitney invented the cotton gin while he was a guest there in 1793. Bonaventure cemetery, with its winding avenues of live-oaks draped with Spanish moss, is one of the country's most beautiful burial-grounds. Savannah has the oldest theatre in the United States still in active use (established 1818), the oldest golf club (1811), and the oldest brick house in the State. The city itself is a favourite winter resort for many Northerners, and there are many bathing beaches, fishing grounds and other pleasure resorts near by, including Tybee island (5 sq.m.) at the mouth of the Savannah river, Montgomery, Thunderbolt and Isle of Hope (where there is a diamond-back terrapin farm). The United States Department of Agriculture has an experimental bamboo farm 12 m. from the city.

Savannah is one of the leading South Atlantic ports. Its water-borne commerce in 1927 amounted to $517,497,229, of which $115,118,264 represented foreign trade, largely exports of raw cotton and naval stores. In 1927 the output of 101 manufacturing establishments situated within the city was valued at $13,573,168. Its cotton warehouses can store 1,000,000 bales, and the two fuel-oil storage plants have a capacity of 16,000,000 gallons. Chief among the manufactures are fertilizers, rosin and turpentine, cotton-seed products and sugar. Bank debits exceed $1,000,000,000 annually. The assessed valuation of the city's taxable property for 1927 was $77,879,118.

The first European settlement in Georgia was made at Savannah in Feb. 1733, by James Edward Oglethorpe. Charles and John Wesley arrived in 1735, and George Whitefield was here in 1738 and 1740–42. Until its capture by the British in 1778, Savannah was the seat of government of Georgia. The first legislature met here on Jan. 1, 1755; the first Provincial Congress on Jan. 18, 1775 and a second on July 4, soon after which the royal Government collapsed and the city was administered by a Council of Safety. Loyalist sentiment was strong, and many families were divided among themselves. From Oct. 1776 to Feb. 1777, the convention which framed the first State Constitution of Georgia was in session in Savannah, and the first State legislature assembled here in May 1778, but on Dec. 9, the British captured the city, and the seat of government was then transferred to Augusta. In May 1782 the British evacuated, after a short siege by Gen. Anthony Wayne, and Savannah was again the capital for a few months. It was chartered as a city in 1789, and soon became a commercial rival of Charleston. In 1819 the first steamship to cross the Atlantic (the "Savannah," built by Savannah capital in the North) sailed from Savannah to Liverpool in 25 days. The convention which adopted Georgia's Ordinance of Secession met here in 1861. The port was blockaded by the Federal Government early in the war, and on Dec. 12, 1862, Ft. Pulaski, commanding the channel at the mouth of the river, was forced to capitulate. Savannah was the objective of Sherman's "march to the sea," and surrendered to him on Dec. 21, 1864.

SAVANTWADI, a native state of Bombay, India. Area, 926 sq.m. Pop. (1921) 206,440. The surface is broken and rugged, interspersed with densely-wooded hills; in the valleys are gardens and groves of cocoa-nut and betel-nut palms. Savantwadi has no considerable rivers; the chief streams are the Karli on the north and the Terakhol on the south. The climate is humid and relaxing, with an average annual rainfall of 150 in. The chief, whose title is *sar desai*, is a Mahratta of the Bhonsla family, who traces back his descent to the 16th century. The town of SAVANTWADI is picturesquely situated on the bank of a large lake, 17 m. E. of the seaport of Vengurla. Pop. (1921) 7,811.

Before the establishment of Portuguese power Savantwadi was the highway of a great traffic between the coast and the interior; but during the 16th and 17th centuries trade suffered much from the rivalry of the Portuguese, and in the disturbances of the 18th century it almost entirely disappeared. In consequence of piracy, the whole coast-line (including the port of Vengurla) was ceded to the British in 1812.

SAVARY, ANNE JEAN MARIE RENÉ, DUKE OF ROVIGO (1774–1833), French general and diplomatist, was born at Marcq in the Ardennes on April 26, 1774. He was educated at the college of St. Louis at Metz and entered the royal army in 1790. He served under Custine on the eastern frontier in 1792, then under Pichegru and Moreau, and in 1798 under Desaix in Egypt, and in Italy. After Marengo Bonaparte gave him command of the gendarmes charged with the duty of guarding the First Consul. In the discovery of the various ramifications of the Cadoudal-Pichegru conspiracy Savary showed great skill and activity. He was in command of the troops at Vincennes when the duc d'Enghien (*q.v.*) was executed. In Feb. 1805 he became general of division. Shortly before the battle of Austerlitz (Dec. 2, 1805) he was sent by Napoleon with a message to the emperor Alexander I. with a request for an armistice, a device which precipitated the attack which brought disaster to the Russians. After the battle Savary again took a message to Alexander, which induced him to treat for an armistice. In the campaign of 1806 Savary showed signal daring in the pursuit of the Prussians after the battle of Jena. Early in the next year he received command of a corps, and gained a success at Ostrolenka (Feb. 16, 1807).

After the treaty of Tilsit (July 7, 1807) Savary proceeded to St. Petersburg as the French ambassador, but was soon replaced by General Caulaincourt (*q.v.*), another accessory to the execution of the duc d'Enghien. But Napoleon needed him in Madrid. With the title of duke of Rovigo, Savary set out for Spain. With Murat Savary made skilful use of the schisms in the Spanish royal family (March–April 1808), and persuaded Charles IV., who had recently abdicated under *duresse*, and his son Ferdinand VII., the *de facto* king of Spain, to refer their claims to Napoleon. Savary induced Ferdinand to cross the Pyrenees and proceed to Bayonne—a step which cost him his crown and his liberty until 1814. In September 1808 Savary accompanied the emperor to the famous interview at Erfurt with the emperor Alexander. On the disgrace of Fouché (*q.v.*) in the spring of 1810, Savary received his appointment, the ministry of police. This office now became a veritable inquisition. Savary was among the last to desert the emperor at the time of his abdication (April 11, 1814) and among the first to welcome his return in 1815, when he became inspector-general of gendarmerie and a peer of France. After Waterloo he accompanied the emperor to Rochefort and sailed with him to Plymouth on H.M.S. "Bellerophon." He was not allowed to accompany him to St. Helena, but underwent several months' "internment" at Malta. Finally he was allowed to return to France and regained civic rights; later he settled at Rome. The July revolution (1830) brought him into favour and in 1831 he received the command of the French army in Algeria. Ill-health compelled him to return to France, and he died at Paris in June 1833.

Lacroix (5 vols., Paris, 1900); *Extrait des mémoires de M. le duc de Rovigo concernant le catastrophe de M. le duc d'Enghien* (London, 1823); *Le Duc de Rovigo jugé par lui-même et par ses contemporains*, by L. F. E. . . . (Paris, 1823); and A. F. N. Macquart, *Réfutation de l'écrit de M. le duc de Rovigo* (1823).

SAVE or **SAVA,** a river of Yugoslavia and an affluent of the Danube. It runs almost parallel with the Drave, both having about the same length. The Save rises in the Triglav group in Carniola from two sources, the Wurzener Save and the Wocheiner Save, which join at Radmannsdorf. It then flows through Carniola and Croatia-Slavonia and joins the Danube at Belgrade. The Save has a length of 442 m., the area of its basin being 34,000 square miles. It is navigable for river steamers from Sisak to its mouth, a distance of 360 miles. (*See* DANUBE.)

SAVERNE or **ZABERN,** a town of France, capital of an arrondissement in the department of Bas-Rhin, on the Rhine-Marne canal and the Zorn, at the foot of a pass over the Vosges, and 27 m. N.W. of Strasbourg by rail. Pop. (1926) 6,954. Saverne (*Tres Tabernae*) was an important place in the times of the Romans, and, after being destroyed by the Alamanni, was rebuilt by the emperor Julian. It is interesting that, being an important point in the line of communications, it early became an ecclesiastical lordship, at first of the bishops of Metz, but from the 13th century to 1793 of the bishops of Strasbourg. It suffered much during the Thirty Years' War, but the episcopal castle, then destroyed, was rebuilt later. There is a 15th century church of a former Franciscan convent. The parish church has a 12th century tower, and 14th century Gothic choir. Saverne is the seat of a sub-prefect and of a cantonal tribunal.

In November 1913 Zabern was the scene of a fracas which caused great bitterness in France and assumed the proportions of an international incident. A German lieutenant named Forstner grossly insulted Alsatian recruits, and a street riot followed. Twenty-nine persons were arrested. On Dec. 2 Forstner caused the arrest of a boy at Zettweiler and struck him with his sabre. The affair led to a vote of censure on Bethmann-Hollweg in the Reichstag, but the military party secured the acquittal of Forstner on appeal to the war council.

SAVIGNY, FRIEDRICH KARL VON (1779–1861), German jurist, was born at Frankfort-on-Main on Feb. 21, 1779. Left an orphan at the age of 13, he was brought up by his guardian until, in 1795, he entered the university of Marburg. After the fashion of German students, Savigny visited several universities, notably Jena, Leipzig and Halle; and returning to Marburg, took his doctor's degree in 1800. In 1803 he published his famous treatise, *Das Recht des Besitzes* (the rights of possession). In 1804 Savigny married Kunigunde Brentano, the sister of Bettina von Arnim and Clemens Brentano the poet, and the same year started on an extensive tour through France and south Germany in search of fresh sources of Roman law.

In 1810 he was called, chiefly at the instance of Wilhelm von Humboldt, to fill the chair of Roman law at the new university of Berlin. Here one of his services was to create, in connection with the faculty of law, a "Sprach-Collegium," an extraordinary tribunal competent to deliver opinions on cases remitted to it by the ordinary courts; and he took an active part in its labours. This was the busiest time of his life. He was engaged in lecturing, in the government of the university, and as tutor to the crown prince in Roman, criminal and Prussian law. In 1814 appeared his pamphlet *Vom Beruf unserer Zeit für Gesetzgebung und Rechtswissenschaft* (new edition, 1892), a protest against the demand for codification.

In 1815 he founded, with Karl Friedrich Eichhorn, and Johann Friedrich Ludwig Göschen (1778–1837), the *Zeitschrift für geschichtliche Rechtswissenschaft,* as the organ of the new historical school. In 1815 appeared the first volume of his *Geschichte des römischen Rechts im Mittelalter,* the last of which was not published until 1831. This work was originally intended to be a literary history of Roman law from Irnerius to the present time. As eventually completed, it left the narrative at the 16th century and the separation of Europe into national States.

In 1835 Savigny began his elaborate work on contemporary Roman law, *System des heutigen römischen Rechts* (8 vols., 1840–1849). In March 1842, he was appointed "Grosskanzler" (High Chancellor), the title given by Frederick II. in 1746 to the official at the head of the juridical system in Prussia, and he carried out several important law reforms in regard to bills of exchange and divorce. In 1848 he resigned and returned to jurisprudence. In 1850 appeared his *Vermischte Schriften,* consisting of a collection of his minor works published between 1800 and 1844. In 1853 he published his treatise on Contracts (*Das Obligationenrecht*), a supplement to his work on modern Roman law, in which he clearly demonstrates the necessity for the historical treatment of law. Savigny died at Berlin on Oct. 25, 1861.

Savigny belongs to the so-called historical school of jurists, though he cannot claim to be regarded as its founder, an honour which belongs to Gustav Hugo. In the history of jurisprudence Savigny's great works are the *Recht des Besitzes* and the *Vom Beruf* above referred to. The former marks an epoch in jurisprudence. Professor Jhering says: "With the *Recht des Besitzes* the juridical method of the Romans was regained, and modern jurisprudence born." Savigny sought to prove that in Roman law possession had always reference to "usucaption" or to "interdicts"; that there is not a right to continuance in possession but only to immunity from interference; possession being based on the consciousness of unlimited power.

The *Beruf unserer Zeit,* in addition to the more specific object the treatise had in view, which has been already treated, expresses the idea, unfamiliar in 1814, that law is part and parcel of national life, and combats the notion, too much assumed by French jurists, especially in the 18th century, and countenanced in practice by Bentham, that law might be arbitrarily imposed on a country irrespective of its state of civilization and past history.

See Biographies by Stinzing (1862); Rudorff (1867); Bethmann-Hollweg (1867); and Landsberg (1890). *See* also ROMAN LAW.

SAVILE, SIR GEORGE (1726–1784), English politician, was the only son of Sir George Savile, Bart. (d. 1743), of Rufford, Nottinghamshire, and was born in London on July 18, 1726. He entered the House of Commons as member for Yorkshire in 1759. In general he advocated measures of relief to Roman Catholics and to Protestant dissenters, and he defended the action of the American colonists. He refused to take office and in 1783 he resigned his seat in parliament. He died unmarried in London on Jan. 10, 1784. Horace Walpole says Savile had "a large fortune and a larger mind"; Burke also had a very high opinion of him.

SAVILE, SIR HENRY (1549–1622), warden of Merton College, Oxford, and provost of Eton, was the son of Henry Savile of Bradley, near Halifax, in Yorkshire. He was educated at Brasenose College, Oxford, where he matriculated in 1561. He became a fellow of Merton in 1565, proceeded B.A. in 1566, and M.A. in 1570. He established a reputation as a Greek scholar and mathematician by voluntary lectures on the *Almagest,* and in 1575 became junior proctor. In 1578 he travelled on the continent of Europe, where he collected manuscripts. On his return he was named Greek tutor to the queen, and in 1535 was established as warden of Merton. He proved a successful and autocratic head under whom the college flourished. A translation of four Books of the Histories of Tacitus, with a learned *Commentary on Roman Warfare* in 1591, enhanced his reputation. On May 26, 1596 he obtained the provostship of Eton, the reward of persistent begging. In February 1601 he was put under arrest on suspicion of having been concerned in the rebellion of the earl of Essex. He was soon released and his friendship with the faction of Essex brought him the favour of James I.

In 1604 Savile was knighted, and in that year he was named one of the body of scholars appointed to prepare the authorized version of the Bible. He was entrusted with parts of the Gospels, the Acts of the Apostles and the Book of Revelation. His edition of Chrysostom (8 vols., fol. 1610–13) was printed by the king's printer, William Norton, in a private press erected at the expense of Sir Henry, who imported the type. At the same press he published an edition of the *Cyropaedia* in 1618. In 1619 he founded and endowed the Savilian professorships of geometry and astronomy at Oxford. He died at Eton on Feb. 19, 1622.

See W. D. Macray, *Annals of the Bodleian Library* (1868); Sir N. C. Maxwell-Lyte, *History of Eton College* (3rd ed., 1899); and John Aubrey, *Lives of Eminent Men* (1898).

SAVINGS BANKS. In any consideration of the dimensions of savings bank deposits, it is impossible to divorce the problem from the effects of the World-War and the post-war period. The general table given below takes this all-important point into account, for it is designed to include 1913, the year immediately preceding the war; 1920, the first year for which comparable figures were available after the war; and 1925, the latest year for which general information was at the time of writing available.

As shown in the articles MONEY and CURRENCY, the general effect of the war and its results was to cause widespread currency depreciation. This had several, and to some extent contradictory, results in the field of savings. To mention the first, which is partly of a theoretical character, if a uniform depreciation of the currency occurs, so that all prices, salaries and wages are doubled, each individual's margin of savings should equally be doubled. Thus if, before the war, a man earned £300 a year, spent £250 a year, and saved £50 a year, after the war, when prices were double, he should, in theory, have earned £600 a year, spent £500 a year and saved £100 a year. Hence it would be natural to find a post-war increase in the total volume of savings, and this, to some extent, the table shows. At the same time, post-war savings are in depreciated money, for even gold has lost one-third of its pre-war purchasing power. To crystallise this argument, the increases in post-war over pre-war savings, as shown by savings bank deposits, do not necessarily prove that the peoples of the world are saving a larger proportion of their income, or that the cult of thrift is increasing. They rather suggest that, as money is worth less to-day than before the war, people have to save more units of money to-day to equal in purchasing power their savings of before the war.

The next general point is the check imposed on savings by a currency in the act of depreciation. This is of a twofold character. Currency depreciation is expressed in rising prices and wages, but every wage-earner and housewife knows that prices rise first, and wages only a considerable time afterwards; so much so that,

as a rule, wages never overtake prices. So long as they lag behind, any margin in the household budget available for savings inevitably disappears, and in many cases past savings have to be drawn upon. This is the check in its first manifestation. The second is that when a currency is depreciating rapidly, saving becomes the act of a fool. What is the use of saving 10,000 marks in a year, only to find, at the end of it, that it takes a million marks to buy a dollar's worth of goods? There is the classic story from Germany of the wastrel who spent his inheritance upon champagne, and then sold the empty bottles for more marks than the champagne had originally cost him, and whether or not this is true, it is obvious that currency depreciation is a serious enemy of thrift. So long as a currency is falling in value, the exercise of thrift is not only an impossibility, but also an act of folly. Hence, while, in such countries, savings bank deposits, measured in worthless paper currency, may apparently be growing, so soon as they are reduced to gold values, they shrink to nothing. As shown later, German deposits in savings banks at the end of 1923 were, measured in paper currency, 100,000,000,000,000,000,000 marks. Reduced to gold marks, they were only 100 millions as against 19,700 millions before the war.

Only when the collapse ends in the stabilisation and revaluation of the currency, is it possible to obtain a true picture, and wherever the collapse has been a severe one, some shrinkage in the nation's savings from pre-war figures is inevitable. Thus, for all practicable purposes, the French franc had been stabilised by the end of 1926. At that date, the total volume of savings was Frs. 15,969,000,000, as against Frs. 5,829,000,000 in 1913. Superficially that suggests a great increase in the traditional thrift of the French nation, but during the intervening period, the franc had fallen to a fifth of its original gold value. To allow for this, the 1926 figure should be divided by five, reducing it to Frs. 3,194,000,000. Finally, gold itself had lost one-third of its pre-war purchasing power, so that even this last figure should be reduced by one-third to Frs. 2,129,000,000. A comparison of this last figure of two milliards with the 1913 figure of nearly six milliards shows the real inroad on French savings bank deposits made by the war and the post-war inflation.

Democratic Banking.—Two other important war tendencies affecting savings banks must also be mentioned. Neither of these is connected with currency depreciation, but both show the way in which new and formidable competitors to the savings banks have come into existence. The first is the gradual democratisation of the ordinary banking system. Fifty years ago, only the rich had banking accounts, but to-day the use of the banks has spread not only to the middle-classes but also to some extent to the artisan classes. Many banks have opened special savings banks departments, and instances of this will be found in the main table; but, in addition, in a large number of cases, people keep their savings on deposit at a bank and not in a special savings bank or savings bank account.

Next come the huge loans raised to finance the war. The belligerent governments had to draw upon the last penny of the nations' capital, and no sum was too small to escape their notice. In fact, most countries issued special forms of loans, designed to appeal to the small investor, who formed the main support of the savings banks. The outstanding example was the British war savings certificate. Sold at 15/6d., it rose to £1 in five years, and to 26/– in ten years, and as no one could hold more than 500, it was limited to the small man. The net equivalent rate of interest on these was over 5%, whereas the British post office savings bank and the Trustee savings banks (*v. infra*) only paid 2½%. The greater appeal of the savings certificate is shown clearly by the fact that, at the end of 1925, 24/– was invested in certificates to every pound deposited at the savings banks.

Finally, the economic losses of the war were reflected in a post-war period of relatively high interest rates, while interest upon savings bank deposits remained unchanged. The disparity in England between the return from savings bank deposits and savings certificates has already been noted. The same applies to interest allowed on deposits by the joint-stock banks. This is two points below bank-rate, and since the war has consequently been

For the value of the various units of currency, *see* separate articles, FRANC, MARK, etc.

*End March, 1927: the total, therefore, cannot legitimately be given.

†In 1913, 1 krone = 20·263 cents. In 1925, 1 schilling = 14.071 cents. Kronen were converted to schillings at the rate of 10,000 "paper" or depreciated kronen to 1 schilling. (*See* KRONE.)

**In 1923, 10·3 millions; in 1924, 14·5 millions.

as high as 5%, and has rarely been below 2%. During most of 1927, it was 2½%. As deposits are accepted in sums as low as £1 and are withdrawable at seven days' notice, the extent of the ordinary bank's competition with the savings bank will be apparent.

This completes the general survey of the post-war position, and will enable the table to be appreciated. The figures are taken from the League of Nations publication, "International Statistical Year-Book, 1926," published in England by Constable and Company, and so may be regarded as being derived from official sources. The writer wishes to place on record the great obligation which he and many others are under to the League Statistical Department for the wealth of information which they made available.

Great Britain.—Apart from deposits in the joint-stock and other banks and in building and co-operative societies, and investments in securities and property of all sorts and descriptions, British savings are held in three main forms, namely, deposits at the Trustee Savings Banks, the Post Office Savings Bank, and holdings of Savings Certificates. Trustee Savings Banks date from the beginning of the nineteenth century, or even earlier (*see* BANKS, HISTORY OF), while the Post Office Savings Bank dates from the middle of the nineteenth century. Savings Certificates, as explained above, were instituted during the war.

The following table shows changes in these three forms of savings, and in the proportion in which the total of savings is divided between them. Amounts are in millions of pounds.

Year	Post office		Trustee banks		Savings certificates		Total £
	£	%	£	%	£	%	
End of							
1913	187·2	73	68·5	27	..	..	255·7
1920	266·5	40	91·3	13	314·9	47	672·7
1921	264·2	38	92·3	14	336·1	48	692·6
1922	268·1	34	98·2	12	413·8	54	780·1
1923	273·1	33	103·1	13	447·5	54	823·7
1924	280·4	33	107·0	13	454·4	54	841·8
1925	285·5	33	110·4	13	472·8	54	868·7
1926	283·7	33	113·9	13	466·0	54	863·6

In analysing this table, it should be noted that the Post Office pays 2½% upon deposits, the Trustee Banks 2½% upon deposits in the ordinary section, and a rather high rate (in 1927, this rate was raised from a maximum of 3½% to one of 4%) on those in the special investment departments of the banks, while, from their institution during the war until March 1922, savings certificates were sold at 15/6d. per one pound certificate, repayable at £1 five years, and at 26/– ten years after the date of purchase. The yield on the last, if held the full time, was about 5½%, and this explains the growth in popularity of the savings certificate, as shown by the changes in the percentage columns. In March 1922, the purchase price was raised to 16/–, and in the autumn of 1923 the 10-year redemption price was reduced to 24/– corresponding to a yield of 4¾%. This rate was more consonant with those allowed by both classes of savings bank, and this explains why, since 1923, the three classes of savings increased proportionately, the percentages remaining unchanged.

In addition to holding deposits, both the Post Office and Trustee Savings Banks purchase and sell gilt-edged stocks and shares on behalf of their depositors and collect the interest thereon. The Post Office has also acted with the Bank of England as joint-issuers of big Government loans, such as 5% War Loan and Funding Loan, to the investing public, and subsequently as registrar of such loans. Stock issued by the Post Office cannot be sold on the market, but must be sold through the Post Office at the market price of the day. The Post Office is also responsible for the administration of Savings Certificates, and will issue annuities to and effect life insurance for the public.

Deposits in the Post Office and Trustee Savings Banks, and holdings of Savings Certificates are limited to £500 (par value in the case of certificates) for each individual. An exception is that when an ex-service man took his war gratuity in the form of savings certificates, they did not count as part of his maximum holding of five hundred.

The following table shows the balance-sheet of the Post Office Savings Bank, as of December 31, 1926. The figures are taken from the official "white paper," which leaves the reader to detect for himself the existence of the surplus of £33,479,180.

Post Office Savings Bank: Balance Sheet, Dec. 31, 1926

LIABILITIES to Depositors		£283,797,505
ASSETS:		
(a) British Government Stock:		
(1) Pre-war stocks . . .	34,546,045	
(2) Long-dated war & post-war stocks . . .	29,651,672	
(3) Short-term stocks (Treasury Bonds, etc.) . .	26,862,919	
(4) Treasury Bills . . .	10,000	
(5) Annuities	86,681,944	177,752,580
(b) Empire Stocks, guaranteed by British Government		71,987,053
(c) Foreign Stocks, guaranteed by British Government		2,136,400
(d) Local Loans Stock, and advances to Local Loans Fund		43,500,686
(e) Advances in relief of trade and unemployment (to Unemployment Fund and under Trade Facilities Act)		17,939,453
(f) Accrued interest and cash balances . .		3,960,513
TOTAL ASSETS . . .		£317,276,685
Surplus of Assets over Liabilities . . .		£ 33,479,180

The final comment on Great Britain must relate to the steady post-war growth in savings, despite bad trade and wide-spread unemployment. Even the coal stoppage of 1926, and its aggravation of an already serious economic and social situation did not cause more than a drop of five millions in total savings, while the Trustee Savings Banks actually improved their position.

(N. E. C.)

UNITED STATES

The name savings banks is differently applied in various parts of the United States but the typical savings bank is a mutual corporation intended to serve as a benevolent institution. In certain States savings banks are conducted as profit-making enterprises by stock corporations. In addition to the specialized savings banks there are many commercial banks maintaining thrift departments which in their functions are similar to savings banks.

The confusion of name between what are strictly savings banks conducted for profit and general banks bearing the title of savings banks makes it difficult to determine from available statistics the exact amount on deposit in stock savings banks, but the figures as of June 30, 1928, for 791 stock savings banks were approximately $1,561,218,000.

Earlier History.—The savings banks in America were adapted from similar enterprises in Great Britain. Groups of persons, usually men of substance and public spirit, secured charters for the purpose of establishing banks for the savings of the poor, the earliest being the Provident Institution for Savings in the Town of Boston, chartered on Dec. 13, 1816. There were in 1928 616 institutions whose avowed purpose was to encourage savings, and without profit to their sponsors. It can no longer be said this appeal is exclusively to the very modestly circumstanced since in New York State as much as $7,500 may be deposited by a single individual and the average amount on deposit per account in that State on June 30, 1928, was $870.96, and in the United States $739.24.

Institutions originally established to serve a particular class early found it advisable to receive deposits from all comers but it is a matter of comparatively recent development that the savings banks seek to serve their depositors with the same business-like deference which well-managed commercial undertakings have found it profitable to employ in dealing with customers. Conversely, commercial banks conducting thrift and savings departments do so as a rule in a spirit of effective service and with no intention to exploit their depositors.

The Mutual Savings Bank.—The operation of a mutual

savings bank is strictly limited by law to the receipt, investment and return of deposits with interest, in addition to minor auxiliary functions performed as services to depositors. The law also strictly limits the type of investment which may be made by such institutions with a view to the greatest possible security of depositors' funds.

The importance of the mutual savings bank in the national economy of the United States is indicated by the fact that according to reports made by the Comptroller of the Currency, on June 30, 1927, the total deposits in such banks were $8,077,099,000, and the total depositors 11,337,398. These banks are situated principally in the New England States, middle Atlantic States, New York, Pennsylvania, Delaware, Ohio and Washington, D.C.

The legal structure and general administrative features of mutual savings banks in the State of New York may be taken as indicating the mutual type of institution of which savings banks of that State are fairly representative.

Organization.—Specific requirements are laid down by statute governing the incorporation of savings banks. Not only must these requirements be met but approval must be obtained from the official having general supervision over the banking institutions in the State. A person is ineligible for election to a board of trustees of a savings bank in New York if by his election a majority of the board shall be members of the boards of commercial banks, trust companies or national banking associations operating a special interest department, or of a mortgage or title company organized under the banking law or insurance law. From time to time, and now usually every three months, the trustees of the bank declare and credit to the depositors dividends at the rate which under the law may not exceed a maximum percentage of 5%.

Savings banks are conceived of as neighbourhood institutions, and in New York State they may have only one branch and only in cities of the first class. In Massachusetts a savings bank may establish one or more branches in the town where the main office is situated and in towns not more than 15 m. distant therefrom where there is no savings bank, but only with the written permission of the commissioner of banks.

All of the earnings and surplus of a savings bank belong exclusively to depositors. In New York, when the undivided profits and guaranty fund as determined under the law amount to more than 25% of the money due depositors, the trustees must at least once in three years divide the accumulation in excess of 25% as an extra dividend to depositors. In Massachusetts such division must be made where the guaranty fund and undivided profits amount to 10½% of the deposits, after an ordinary dividend is declared.

The investments of all savings banks are governed by the law of the States in which they are situated. In New York State, savings banks may invest in the stocks and bonds of the United States, of any State of the Union, the District of Columbia, and of the cities of such States which meet certain tests as to size and powers and record of responsibility in the payment of its debts. They may invest in the mortgage bonds of railroad corporations meeting certain fiscal qualifications and which have regularly and punctually paid the maturities of principal and interest on their indebtedness for a fixed period preceding the date of the investment, and also in certain other bonds specifically named in the statute. In 1928 they were authorized to invest in the securities of public utility corporations and in railway equipment trust certificates under specific restrictions. They may invest in bankers' acceptances eligible for purchase by the Federal Reserve Bank, in promissory notes secured by collateral eligible for savings bank investments and in loans secured by the pass-books of depositors.

On Jan. 1, 1929, 63% of the combined assets of the mutual savings banks of the State of New York were invested in bond and mortgage on real estate.

Supervision.—Semi-annually a New York savings bank is required to make a written report to the superintendent of banks on a form prescribed by the superintendent, covering full details of the transactions of the bank. There is a drastic penalty imposed for the failure of the bank to make such reports. Supplementing these reports the superintendent from time to time makes unannounced examinations of the records and transactions of the bank.

Similar although not identical provisions are contained in the laws of other States. Thus once a year in Massachusetts a thorough examination and audit of the bank must be made by a certified public accountant, not connected with the bank, selected by the auditing committee of the trustees and approved by the bank commissioner. In the event that the committee fails to have such an examination made, the commissioner must have one made and the bank must pay for it.

These rigid restrictions, on the operation of mutual savings banks with a view to maintaining their integrity, arose out of early disastrous experiences with irresponsibly managed banks. The steady improvement in the standards of business morality, the effect of supervision by State officials, advances in methods of accounting and internal administration, and also the growth of competition between banks for the business of the public have all contributed to the present general high level of efficiency and responsibility of the management of banks, only emphasized by occasional individual lapses.

A considerable number of banks organized under State charters have established thrift departments. Commercial banks have accumulated in the State of New York alone upwards of $2,817,882,000 of thrift deposits (1928). These funds are not subject to segregation for special investment and may be commingled with the general funds of the bank and used in any manner in which such general funds may be used. The growth of deposits of this character is a reflection of the increased public confidence with which banks generally are held by the working class.

Extended Facilities.—Savings banks maintain and are increasingly establishing service departments to give counsel on investments, to help in the preparation of family and individual budgets, to advise regarding the use of funds, and to explain the functions of the savings bank not only to depositors but to such part of the public as comes within the walls of a bank seeking information. The progressive savings banks responding to the modern spirit of business are reaching out to encourage the public to make a maximum use of the institutions which have achieved prestige and stability, and therefore have it within their power to serve a large number of individuals satisfactorily. Some of these banks now have individually several hundred thousand depositors. Through educational publicity special forms of accounts intended to stimulate regular savings, promotion of savings for specific objects such as the purchase of a home, making of investments or the accumulation of funds for life insurance, have been developed, showing marked ingenuity in enlarging the use of the savings bank.

Stock Savings Banks.—Stock Savings Banks are organized for the purpose of making profit for their owners and are conducted by boards of directors selected by the stockholders. These banks generally exist in States where mutual savings banks have not been established. In certain cases they perform a savings bank business exclusively. In other cases the savings department is conducted as a part of the general operation of a commercial bank. These banks are organized and carried on in certain States under the general banking laws, in others under special laws regulating the operation of a savings bank.

School Savings.—The school savings bank is an imported idea brought to the United States by John H. Thiry, a savings bank official of Long Island city, and was modelled after those of France, Belgium and Germany. As a trustee of the public schools of Long Island city, Thiry found no difficulty in gaining the consent of his fellow trustees to try the experiment in those schools. From that experiment which proved successful the school savings bank idea spread until it received the general endorsement of educators as well as bankers. It has been legalized in numerous States and in the principal individual States school savings have assumed impressive proportions. There are several plans of operating a school savings bank but they are alike in that they are subsidiary to a savings or other bank in which

money collected from the children is ultimately deposited. The essential idea is that each child should be dealt with as an individual depositor, with the customary evidence of his or her status as such, as, for example, the possession of a pass book in which his or her transactions with the bank are recorded. Children taught to save in school savings banks become users of savings banks after school years. In June 1928 there were in the United States 13,835 schools with savings plans; 3,980,237 children were reported participating in them with deposits of $26,005,138.04 and net savings of $9,476,391.32.

Postal Savings System.—Under a board of trustees consisting of the postmaster general, the secretary of the Treasury and the attorney general, acting ex officio, the U.S. Government since 1910 has maintained postal savings depository offices. Accounts as low as $1.00 may be opened by persons over ten years of age. Interest at 2% per annum is allowed and is credited once a year. Individual balances may not exceed $2,500. Deposits in sums of $20 or multiples thereof may be converted by the depositor into U.S. Government bonds bearing interest at 2½%. At the close of the fiscal year 1928, there were 6,683 depositories in operation; $152,143,349 was on deposit to the credit of 412,250 depositors with an average balance per depositor of $369.06.

The system is self-supporting showing a profit of $618,602.32 in 1928.

Postal savings banks, being backed by the pledged credit of the U.S. Government, were intended to encourage thrift, supplementing the activity of banking institutions. It was expected that they would keep in the country part of the money previously sent abroad on international money orders, bring hoarded money into circulation, and offer facilities to the timid and fearful in times of financial stress.

For the first 17½ years of its operation the postal savings system received on deposit $1,586,498,397, of which $1,252,326,472 had been repaid. While it is to be doubted that the postal savings system has accomplished all that was expected of it, it is unquestioned that the system is now regarded as a permanent part of the financial machinery of the nation. (H. Bru.)

FRANCE AND GERMANY

France.—Two classes of savings banks exist, namely, the "Caisses d'Epargne Ordinaires," or private institutions, and the Caisse Nationale or Caisse d'Epargne Postale, this being the state savings bank administered by the Post Office. As is shown by the following table, the major part of the nation's savings is deposited in the private banks. The table also shows the post-war increases in nominal savings, and their actual decrease when reduced to gold values. Figures are in millions of francs (franc= $0·0392).

Year	Deposits in		Total* deposits	Total deposits (reduced to gold values)
	Caisses* ordinaires	Caisse* nationale		
End of 1913	4,011	1,818	5,829	5,829
" " 1920	5,795	2,353	8,148	2,500
" " 1921	6,884	2,697	9,581	3,960
" " 1922	7,796	3,051	10,848	4,078
" " 1923	8,286	3,271	11,558	3,066
" " 1924	8,577	3,419	11,996	3,374
" " 1925	9,831	3,937	13,768	2,705
" " 1926	†	†	15,969	3,258

*These statistics are taken from *La France Economique en 1926*, p. 247.
†Not available.

The net result is a fall in the gold value of French savings bank deposits from 5,829 millions at the end of 1913 to 3,258 millions at the end of 1926. This bears out the general theory enunciated in the first section of this article.

The results for 1926 illustrate, in striking fashion, the extent of the blow dealt to thrift by a depreciating currency. It will be remembered that, at the opening of the year, the franc stood at 3·70 cents, or 130 francs to the pound, and then fell steadily until, in July, it fell as low as 2·03 cents, or 240 francs to the pound. In July alone it fell from 2·67 to 2·03 cents, or by 24%. The result was that this month witnessed a sudden rush on the part of the public to withdraw their savings, and in this month the Caisse Nationale lost 133·7 million francs, and the Caisses Ordinaires lost 53 millions. The run on the latter institutions continued into August, possibly because of the time that elapses between a depositor giving notice of withdrawal and the actual withdrawal, and in the first ten days of that month as many as 88 millions were withdrawn. By September, the financial situation was in hand, and confidence was restored. The result was a steady increase in deposits.

The depreciation of the franc has rendered necessary large increases in the maximum sum permitted to be held by any single depositor. Before the war, it was only 1,500 francs. This limit was raised in 1916, 1919, 1925 and again in 1926, and in accordance with the provisions made in the last year, it stands at 12,000 francs for an individual, and at 50,000 for a "society." As 1,500 francs pre-war equal 7,500 francs to-day, it will be seen that the limits have been raised by a far greater extent than was required by the depreciation of the franc.

Germany.—German Savings Banks are organised into thirteen District Associations, together with two separate banks owned by the provinces of Rhineland and Westphalia. Prior to the war, deposits therein amounted to 19,700 million marks. The post-war position is shown in the following table. All figures are in millions of marks.

Year	Savings banks deposits	
	Actual	Gold equivalent
End of		
1913	19,700	19,700
1917	25,403	21,200
1918	31,834	16,400
1919	36,981	3,105
1920	44,563	2,575
1921	*	*
1922	*	*
1923	*	100
1924	608	608
1925	1,694	1,694
1926	3,091	3,091
1927	4,665	4,665

*Owing to the depreciation of the mark, the figures became meaningless. 1923 is given as the anticlimax. The actual total was 100,000,000,000,000,000 paper marks. The figures for 1924 and onwards are in new Reichsmarks. (*See* Mark.)

These statistics afford a clear example of the way in which savings lose their real value when the currency collapses. The real shrinkage began in the closing year of the war, and continued until, with the final disappearance of the old mark in 1923 as a result of inflation, savings had fallen to one-twentieth of their pre-war volume.

Following the revaluation of the mark at the ratio of one new Reichsmark to one billion paper marks, legislation was passed to determine the amounts due by savings banks to their depositors. It was obviously impossible to reach an arrangement that was both equitable and practicable. The following provisions were made:—

Savings accounts in public savings institutions or in savings banks under Government supervision were revalued by dividing the Estate "available for distribution," *i.e.*, the revalued assets of the savings banks and other available assets of the debtor. The amount so distributed was to aggregate not less than 12½% of the gold mark value of such deposits. (Authority, *Moody's Manual of Investments*, 1928.) In other words, every attempt was to be made to secure for depositors one-eighth of their original savings.

Once confidence was restored by the revaluation of the mark, savings again began to accumulate. By the end of January, 1928, they had reached 5,094 million marks. It will clearly be a long process to overcome the destructive effects of the war and the subsequent period of inflation, so as to restore savings bank deposits to the pre-war level. (N. E. C.)

SAVINKOV, BORIS (pen-name, Ropshin) (d. 1925), Russian revolutionary, joined the Russian socialist-revolutionary party at the beginning of the 20th century and reached a high position in the councils of the party, becoming one of the five members of its "Militant Organisation" and thus jointly responsible with the other members of that committee for the planning and execution of numerous terrorist assassinations. During the years immediately preceding 1914 he withdrew from active membership of the party, and in his novel *The White Horse* revealed a deeply pessimistic view of the position of the "intelligentsia" in pre-war Russia. From 1914 onwards he took a strongly pro-war attitude, and after the February 1917 revolution he became Kerensky's able assistant, holding the position of vice-minister for war in the 2nd coalition government of August. He played an equivocal part in the Kornilov affair, and after the Bolshevik revolution devoted himself to anti-Soviet activities. He was caught by the G.P.U. secretly entering Soviet Russia for purposes never clearly elucidated, was brought to trial in Moscow for his anti-Soviet activities, and was sentenced to ten years' imprisonment. He died in prison in 1925.

SAVOFF, MICHAEL (1857–1928), Bulgarian general and statesman, after three years in the Russian Staff Academy in St. Petersburg, became a captain in the Bulgarian army when, on the outbreak of war with Serbia, he commanded one wing of the Bulgarian army at their brilliant victory of Slivnitza. In 1887 he was appointed assistant to the Minister of War, and in 1891 minister. He resigned in 1897, but after a further period in the army, and as commandant of the Military Academy at Sofia, he again held the same office in 1902 in Petroff's cabinet. The military law of 1904 was largely due to him. He retired into private life in 1908, but was appointed commander-in-chief of the Bulgarian army during the 1st and 2nd Balkan wars (1912–13). Savoff signed the orders of June 29, 1913, commanding the Bulgarian Fourth Army to attack the Greek and Serbian force, thus opening the second Balkan War. For this he was recalled and an enquiry opened which was, however, never concluded; Savoff declared that the order had been given him by King Ferdinand. Although holding no command in the World War, owing to ill health, he strongly urged that Bulgaria join the Central Powers in order to recover Macedonia from Serbia. In Sept. 1918 he returned to Bulgaria from abroad in an attempt to overthrow the Malinoff Cabinet, and keep Bulgaria in the War, but found that King Ferdinand had already abdicated. On Oct. 22, 1922, he was appointed Bulgarian minister in Paris, but retired after the anti-Agrarian *coup d'état* of June 9, 1923. He died on July 22, 1928, at Vallier-de-Thiey, Alpes-Maritimes.

SAVOIE, a department of France, formed in 1860 of the old provinces of Haute Savoie, Savoie, the Tarentaise and the Maurienne, which constituted the southern portion of the duchy of Savoy. It is bounded north by the department of Haute Savoie, east and south-east by Italy, south-west by the department of the Hautes Alpes, and west by those of the Isère and the Ain. Pop. (1926) 231,210; area 2,388 sq.m. It is mainly made up of the basin of the Isère. Probably the Isère formerly communicated with the Rhone past Chambéry and the Lac du Bourget. The sources of the Isère and of the Arc are separated by the ridge of the Col du Mont Iseran (9,085 ft.). The loftiest points are the Grande Casse (12,668 ft.), the culminating summit of the Vanoise group, the Mont Pourri (12,428 ft.), the Pointe de Charbonel (12,336 ft.), the Aiguille de la Grande Sassière (12,323 ft.), the Dent Parrachée (12,179 ft.), the Levanna (11,943 ft.) and the Aiguilles d'Arves (11,529 ft.). A small portion of the department (including both shores of the Lac du Bourget) is in the part of the duchy of Savoy neutralised in 1815. The chief products are cattle and dairy-products and wine. There are general manufactures and tobacco is grown. It is divided into 3 arrondissements (Chambéry, the chief town, Albertville and St. Jean de Maurienne), 29 cantons and 330 communes. It forms the dioceses of Chambéry (an archbishopric), Moutiers-Tarentaise, St. Jean de Maurienne and Anneçy, it is in the XIVth military region (Lyons), and is in the académie (educational division) of Chambéry, where is its court of appeal. There are mineral springs at Aix-les-Bains (*q.v.*), while other sulphur springs rise at Marlioz and at Challes, those of Salins being saline, and those of Brides (the best known after Aix) alkaline. For the history of the district *see* SAVOY, HOUSE OF.

See J. J. Vernier, *Dict. top. du dèp. dé la Savoie* (Chambéry 1897).

SAVONA, a seaport and episcopal see of Liguria, Italy, the capital of the province of Savona, 27 m. W.S.W. of Genoa by rail, 33 ft. above sea-level, and after Genoa and Nice the most important of the cities of the Riviera. Pop. (1921) 53,063, town; 58,711, commune. The greater part of the town is now modern with fine streets with porticoes. It is surrounded with green-clad hills and luxuriant orange groves. Near the shore stands the castle built by the Genoese in 1542, on the area of the old cathedral, and now occupied by large iron-works. The cathedral (1589–1604) is a late Renaissance building with a 12th century font, fine choir-stalls and pulpit (1500). In the Cappella Sistina, to the north, stands the finely carved tomb erected by Sixtus IV. to his parents. Facing the cathedral is the Della Rovere palace erected by Cardinal Giulio della Rovere (Julius II.) from the plans of Giuliano da Sangallo, now occupied by various public buildings, the prefecture, the post-office and law-courts. The municipal picture gallery is interesting, and there are some fine old buildings in the town. Good majolica was made in the 16th, 17th and 18th centuries. The Teatro Chiabrera was erected in 1853 in honour of the lyric poet Chiabrera (1552–1637). The harbour, dating from 1815, has since 1880 been provided with a dock excavated in the rock, 986 ft. long, 460 ft. wide and 23 ft. deep. Savona is one of the chief seats of the Italian iron industry, having iron-works and foundries, shipbuilding, railway workshops, a railway signal factory, engineering shops, brass foundry, tinplate works, sulphur mills and glass-works. In 1926 1,610 vessels of 1,251,207 tons entered and cleared the port, dealing with 1,301,070 tons of merchandise, of which 1,202,967 tons were imports, almost entirely foreign coal and petrol. The coal is dealt with by an extensive telferage system. There is a railway through the mountains from Savona to Turin (91 m. N.N.W.).

Savona is the ancient *Savo,* a town of the Ingauni (*see* ALBENGA), but less important than Vada Sabatia (Vado), 4 m. to the W., up to which the coast road from Rome was reconstructed in 109 B.C., from which a road diverged across the Apennines to Placentia. In 1191 Savona bought up the territorial claims of the marquesses Del Carretto. Its whole history is that of a long struggle against the preponderance of Genoa. As early as the 12th century the Savonese built themselves a sufficient harbour; but in the 16th century the Genoese, fearing that Francis I. of France intended to make it a great seat of Mediterranean trade, rendered it useless by sinking at its mouth vessels filled with large stones.

SAVONAROLA, GIROLAMO (1452–1498), Italian monk and reformer, born at Ferrara on Sept. 21, 1452, was the third child of Michele Savonarola and his wife Elena Bonaccossi of Mantua. Elena was tenderly loved by her famous son, and his letters prove that she retained his fullest confidence through all the vicissitudes of his career. Girolamo was intended for the medical profession, but even as a boy he had intense pleasure in reading St. Thomas Aquinas and the Arab commentators of Aristotle, was skilled in the subtleties of the schools, wrote verses and studied music and design. To the mystic young student all festivities were repulsive, and although reared in a courtier-household he early asserted his individuality by his contempt for court life. At the age of 19 he was passionately in love with the daughter of a neighbour, a Strozzi exiled from Florence, but his suit was repulsed with disdain and this probably decided his career. He was full of doubt and self-distrust, but in 1474 his doubts were dispelled by a sermon heard at Faenza and he entered the monastery of St. Domenico at Bologna, where his novitiate was marked by a fervour of humility. He passed six quiet years in the convent, but his poems written during that period are expressive of burning indignation against the corruptions of the church.

In 1482 he reluctantly accepted a mission to Ferrara, and later he was sent to the convent of St. Mark in Florence. In 1483 he was Lenten preacher in the church of St. Lorenzo, but his plain,

earnest exhortations attracted few hearers. His first success as a preacher was gained at San Gimignano (1484–85), but it was only at Brescia in the following year that his power as an orator was fully revealed. In a sermon on the Apocalypse he shook men's souls by his terrible threats of the wrath to come, and drew tears from their eyes by the tender pathos of his assurances of divine mercy. Soon, at a Dominican council at Reggio, Savonarola had occasion to display his theological learning and subtlety. The famous Pico della Mirandola was particularly impressed by the friar's attainments, and is said to have urged Lorenzo de' Medici to recall him from Lombardy. When Savonarola returned to Florence in 1490, his fame as an orator had gone there before him, and on Aug. 1, 1490, he first preached in the church of St. Mark.

Prior of St. Mark's.—In 1491 he was invited to preach in the cathedral, and his rule over Florence may be said to begin from that date. Lorenzo sent leading citizens to him to urge him to show more respect to the head of the state. Savonarola rejected their advice and foretold the impending deaths of Lorenzo, of the pope and of the king of Naples. In the July of the same year he was elected prior of St. Mark's. As the convent had been rebuilt by Cosimo, and enriched by the bounty of the Medici, it was considered the duty of the new superior to present his homage to Lorenzo. Savonarola, however, refused to conform to the usage. His election was due to God, not Lorenzo. In April 1492, Lorenzo de' Medici was on his death-bed at Careggi. Oppressed by the weight of his sins, he summoned the unyielding prior to shrive his soul. Savonarola reluctantly came and offered absolution upon three conditions. Lorenzo asked in what they consisted. First, "You must repent and feel true faith in God's mercy." Lorenzo assented. Secondly, "You must give up your ill-gotten wealth." This, too, Lorenzo promised, after some hesitation; but upon hearing the third clause, "You must restore the liberties of Florence," Lorenzo turned his face to the wall and made no reply. Savonarola waited a few moments and then went away. And shortly after Lorenzo died unabsolved.

Savonarola's influence now rapidly increased. The same year Innocent VIII. died (July 1492) and men's minds were full of anxiety, an anxiety increased by the scandalous election of Cardinal Borgia to the papal chair. During the delivery of one of his Advent sermons, Savonarola beheld the vision, recorded in contemporary medals and engravings, that is almost a symbol of his doctrine. A hand appeared to him bearing a flaming sword inscribed with the words: "Gladius Domini supra terram cito et velociter." He heard supernatural voices proclaiming mercy to the faithful, vengeance on the guilty, and mighty cries that the wrath of God was at hand. Then the sword bent towards the earth, the sky darkened, thunder pealed, lightning flashed, and the whole world was wasted by famine, bloodshed and pestilence. He was presently addressing enthusiastic congregations at Prato and Bologna whence he returned to Florence. He was rapturously welcomed by the community of St. Mark's, and at once proceeded to re-establish the discipline of the order. For this purpose he obtained, after much difficulty, a papal brief emancipating the Dominicans of St. Mark from the rule of the Lombard vicars of that order. He thus became an independent authority, no longer at the command of distant superiors. He relegated many of the brethren to a quieter retreat outside the city, only retaining in Florence those best fitted to aid in intellectual labour. Meanwhile he thundered forth predictions of heavenly wrath. In 1494 the duke of Milan demanded the aid of France, and King Charles VIII. brought an army across the Alps. The incompetent policy of Piero de' Medici, Lorenzo's successor, towards Charles drove Florence to revolt. But even at this crisis Savonarola's influence was all-powerful, and a bloodless revolution was effected. The resuscitated republic sent a fresh embassy to the French king, to arrange the terms of his reception in Florence. Savonarola was one of the envoys, Charles being known to entertain the greatest veneration for the friar who had so long predicted his coming and declared it to be divinely ordained. Charles entered Florence on Nov. 17, 1494, but the exorbitance of his demands soon showed that he came as a foe. The signory resolved to be rid of their dangerous guest; and, when Charles threatened to sound his trumpets unless the sums exacted were paid, Capponi tore up the treaty in his face and made the memorable reply: "Then we will ring our bells." The monarch, alarmed at the dangerous possibilities of fighting in the narrow streets of the city, accepted moderate terms, and, yielding to Savonarola's remonstrances, left Florence on Nov. 24.

The citizens turned to the patriot monk whose words had freed them of King Charles, and Savonarola became the law-giver of Florence. The first thing done at his instance was to relieve the starving populace within and without the walls; shops were opened to give work to the unemployed; all taxes, especially those weighing on the lower classes, were reduced; the strictest administration of justice was enforced, and all men were exhorted to place their trust in the Lord. And, after much debate as to the constitution of the new republic, Savonarola's influence carried the day in favour of Soderini's proposal of a universal or general government, with a great council on the Venetian plan. Savonarola's programme of the new government was comprised in the following formula: (1) fear of God and purification of manners; (2) promotion of the public welfare in preference to private interests; (3) a general amnesty to political offenders; (4) a council on the Venetian model, but with no doge. At first the new machinery acted well; the public mind was tranquil.

Dictator of Florence.—Without holding any official post in the commonwealth he had created, the prior of St. Mark's was the dictator of Florence, and guarded the public weal with extraordinary political wisdom. At his instance the tyrannical system of arbitrary imposts and so-called voluntary loans was abolished, and replaced by a tax of 10% (*la decima*) on all real property. His counsels were always given as addenda to the religious exhortations in which he denounced the sins of his country and the pollution of the church, and urged Florence to cast off iniquity and become a truly Christian city, a pattern not only to Rome but to the world at large. His eloquence was now at the flood. Pleasure-loving Florence was completely changed. Abjuring pomps and vanities, its citizens observed the ascetic régime of the cloister. Hymns and psalms rang in the streets that had so recently echoed with Lorenzo's dissolute songs. Both sexes dressed with Puritan plainness; husbands and wives quitted their homes for convents and persons of all ranks—nobles, scholars and artists—renounced the world to assume the Dominican robe. Still more wonderful was Savonarola's influence over children, and their response to his appeals is a proof of the magnetic power of his goodness and purity. He organized the boys of Florence in a species of sacred militia and it was with the aid of these youthful enthusiasts that Savonarola arranged the religious carnival of 1496, when the citizens gave their costliest possessions in alms to the poor, and tonsured monks, crowned with flowers, sang hymns and performed wild dances for the glory of God. In the same spirit, and to point the doctrine of renunciation of worldly enjoyments, he celebrated the carnival of 1497 by the famous "burning of the vanities" (*i.e.* masks and other objects pertaining to the carnival festivities, indecent books and pictures, etc.) in the Piazza della Signoria. Nevertheless the artistic value of the objects consumed has been greatly exaggerated by some writers. Savonarola was foe neither to art nor to learning. On the contrary, so great was his respect for both that, when there was a question of selling the Medici library to pay that family's debts he saved the collection at the expense of the convent purse.

Conflict with the Pope.—Meanwhile his uncompromising spirit roused the hatred of political adversaries as well as of the degraded court of Rome. Even now, when his authority was at its highest, when his fame filled the land, and the vast cathedral and its precincts lacked space for the crowds flocking to hear him, his enemies were secretly preparing his downfall. Events were taking a turn hostile to the prior and Alexander VI., having seen a transcript of one of Savonarola's denunciations of his crimes, resolved to silence this daring preacher.

Bribery was the first weapon employed, and a cardinal's hat was held out as a bait. But Savonarola indignantly spurned the offer. So long as King Charles remained in Italy Alexander's concern for his own safety prevented vigorous measures against the

friar, but no Borgia ever forgave an enemy. He bided his time and in July 1495, a papal brief courteously summoned Savonarola to Rome. In terms of equal courtesy the prior declined the invitation, nor did he obey a second less softly worded, in September. Then came a third, threatening Florence with an interdict in case of renewed refusal. Savonarola disregarded the command, but went to preach for a while in other Tuscan cities. But in Lent his celebrated sermons upon Amos were delivered in the Duomo, and again he urged the necessity of reforming the church, striving by ingenious arguments to reconcile rebellion against Alexander with unalterable fidelity to the Holy See. Alexander now issued a brief, uniting St. Mark's to a new Tuscan branch of the Dominicans, thus depriving Savonarola of his independent power, while Piero de' Medici's followers continued their intrigues, and party spirit increased in virulence. The citizens were growing weary of the monastic austerities imposed on them, and Alexander foresaw that his revenge was at hand.

A signory openly hostile to Savonarola took office in May, and, in feigned anxiety for the public peace, besought him to suspend his discourses. Shortly afterwards the threatened bull of excommunication was launched against him, and Fra Mariano was in Rome stimulating the pope's wrath. Savonarola remained undaunted. The sentence was null and void, he said. His mission was divinely inspired; and Alexander, elected simoniacally and laden with crimes, was no true pope. Nevertheless the reading of the bull in the Duomo with the appropriate, terrifying ceremonial, made a deep impression on the Florentines. But in July Savonarola's friends were again in power and did their best to have his excommunication removed. During this time Rome was horror-struck by the mysterious murder of the young duke of Gandia, and the bereaved pope mourned his son with the wildest grief. Savonarola wrote him a letter of condolence, boldly urging him to bow to the will of Heaven and repent while there was yet time.

Florence then was plunged in new troubles through Medicean intrigues, and a conspiracy for the restoration of Piero was discovered and resulted in the execution of five leading citizens including Bernardo del Nero, a very aged man of lofty talents and position. It is said that at least Bernardo del Nero would have been spared had Savonarola raised his voice, but the prior would not ask mercy for them. This silence proved fatal to his popularity with moderate men. He was now interdicted from preaching even in his own convent and again summoned to Rome. As before, the mandate was disobeyed. He refrained from public preaching, but held conferences in St. Mark's with large gatherings of his disciples, and defied the interdict on Christmas Day by publicly celebrating mass and heading a procession through the cloisters. In 1498 the Piagnoni, as Savonarola's followers were called, were again at the head of the state, and at their request the prior resumed his sermons in the Duomo, while his dearest disciple, Fra Domenico Buonvicini, filled the pulpit of St. Lorenzo. For the last time the carnival was again kept with strange religious festivities, and some valuable books and works of art were sacrificed in a second bonfire of "vanities." But menacing briefs poured in from Rome, the city itself was threatened with interdict, and the Florentine ambassador could barely obtain a short delay. Now, too, the Piagnoni quitted office; the new signory was less friendly, and the prior was persuaded by his adherents to retire to St. Mark's. Alexander now demanded that the Florentines should silence the man themselves or send him to be judged by a Roman tribunal. Savonarola now despatched letters to the rulers of Europe adjuring them to assemble a council to condemn this antipope. But the papal threats were now urgent, and the signory entreated Savonarola to cease preaching. He obeyed, and concluded his last discourse with the most touching farewell.

The government hoped that Alexander would be appeased and Florence allowed to breathe freely. But although silenced, the prophet was doomed. A creature of the Arrabbiati, a Franciscan friar named Francesco di Puglia, challenged Savonarola to prove the truth of his doctrines by the ordeal of fire. At first the prior treated the provocation with merited contempt, but his too zealous disciple Fra Domenico accepted the challenge and, when the Franciscan declared that he would enter the fire with Savonarola alone, Fra Domenico protested his willingness to enter it with any one in defence of his master's cause. As Savonarola resolutely declined the trial, the Franciscan deputed a convert, one Giuliano dei Rondinelli, to go through the ordeal with Fra Domenico. Savonarola, perceiving that a trap was being laid for him, discountenanced the "experiment" until his calmer judgment was at last overborne by the fanaticism of his followers. On April 7, 1498, an immense throng gathered in the Piazza della Signoria to enjoy the barbarous sight. The Dominicans, led by Savonarola, and the Franciscans came forward, but neither Rondinelli nor Fra Francesco appeared and there were angry disputes between the two groups of friars. It was now late in the day, and a storm shower gave the authorities a pretext for declaring that heaven was against the ordeal. The Franciscans slipped away unobserved, but Savonarola raising the host attempted to lead his monks across the piazza in solemn order as before. On this the popular fury burst forth. Defrauded of their cruel diversion, the people were wild with rage. Fra Girolamo's power was suddenly at an end. Against the real culprits, the Franciscans, no anger was felt; the zealous prior, the prophet and lawgiver of Florence, was made the popular scapegoat. Notwithstanding the anguish that must have filled his heart, the fallen man preserved his dignity and calm. Mounting his own pulpit in St. Mark's he quietly related the events of the day to the faithful assembled in the church, and then withdrew to his cell, while the mob outside clamoured for his blood.

Arrest and Trial.—The next morning the government decided on his arrest, and no sooner was this made public than the populace rushed to the attack of the convent. The monks and their few remaining friends made a most desperate defence. In vain Savonarola besought them to lay down their arms. When the church was finally stormed Savonarola was seen praying at the altar, with Fra Domenico, armed with an enormous candlestick, guarding him from the blows of the mob. A few disciples dragged their beloved master to the inner library and urged him to escape, when a cowardly monk, one Malatesta Sacramoro, cried out that the shepherd should lay down his life for his flock. Thereupon Savonarola turned, bade farewell to the brethren, and, accompanied by the faithful Domenico, quietly surrendered to his enemies. The prisoners were conveyed to the Palazzo Vecchio.

Now came an exultant brief from the pope. His well-beloved Florentines were true sons of the church, but must crown their good deeds by despatching the criminals to Rome. The signory refused to send their prisoners to Rome but they did Rome's behests. Day after day Savonarola was tortured, and in his agony, with a frame weakened by constant austerity and the mental strain of the past months, he made every admission demanded by his tormentors. But directly he was released from the rack he always withdrew the confessions uttered in the delirium of pain. These being too incoherent to serve for a legal report, a false account of the friar's avowals was drawn up and published. Alexander was frantically eager to see his enemy die in Rome. But the signory insisted that the false prophet should suffer death before the Florentines whom he had so long led astray. The matter was finally compromised. A second mock trial was held by two apostolic commissioners specially appointed by the pope. Meanwhile the trial of Brothers Domenico and Silvestro was still in progress. The former remained faithful to his master and himself. No extremity of torture could make him recant or extract a syllable to Savonarola's hurt; he steadfastly repeated his belief in the divinity of the prior's mission. Fra Silvestro on the contrary gave way at mere sight of the rack, and owned himself and his master guilty of every crime laid to their charge.

The two commissioners soon ended their task. They had the pope's orders that Savonarola was to die "even were he a second John the Baptist." On three successive days they "examined" the prior with worse tortures than before. On May 22 sentence of death was pronounced on him and his two disciples. Savonarola listened unmoved to the awful words and then quietly resumed his interrupted devotions. Fra Domenico exulted in the thought of dying by his master's side; Fra Silvestro, on the contrary, raved with despair. The only favour Savonarola craved before death was a short interview with his fellow victims. This

the signory unwillingly granted. The memorable meeting took place in the hall of the Cinquecento. During their 40 days of confinement and torture each one had been told that the other had recanted, and the false report of Savonarola's confession had been shown to the two monks. The three were now face to face for the first time. Fra Domenico's loyalty had never wavered, and the weak Silvestro's enthusiasm rekindled at sight of his chief. Savonarola prayed with the two men, gave them his blessing, and exhorted them by the memory of their Saviour's crucifixion to submit meekly to their fate. The following morning he prophesied that dire calamities would befall Florence during the reign of a pope named Clement. The carefully recorded prediction was verified by the siege of 1529.

The execution took place the same morning. First came the ceremonial of degradation. Sacerdotal robes were thrown over the victims, and then roughly stripped off by two Dominicans, the bishop of Vasona and the prior of Sta. Maria Novella. To the bishop's formula, "I separate thee from the church militant and from the church triumphant," Savonarola replied: "That is beyond thy powers." His disciples' bodies already dangled from the arms of the cross before he was hung on the centre beam. Then the pile was fired. At dusk the martyrs' remains were thrown into the Arno.

Every year on the anniversary of Savonarola's martyrdom flowers are strewn on the spot where it took place.

Savonarola's writings may be classed in three categories:—(1) numerous sermons, collected mainly by Lorenzo Violi, one of his most enthusiastic hearers; (2) an immense number of devotional and moral essays and some theological works, of which *Il Trionfo della Croce* is the chief; (3) a few short poems and a political treatise on the government of Florence. Although his faith in the dogmas of the Roman Catholic Church never swerved, his strenuous protests against papal corruptions, his reliance on the Bible as his surest guide, and his intense moral earnestness undoubtedly connect Savonarola with the movement that heralded the Reformation.

Casanova have published a *Scelta di prediche e scritti di Frà Girolamo Savonarola con nuovi documenti* (Florence, 1898); *Il Savonarola e la critica tedesca* (Florence, 1900), a selection of translations from the German. *See* also Schnitzer, *Quellen und Forschungen zur Geschichte Savonarolas* (1902).

(P. V.; L. V.)

SAVOY, HOUSE OF, a dynasty which ruled over the territory of Savoy and Piedmont for nine centuries, and now reigns over the kingdom of Italy. The name of Savoy (Sabaudia) was known to the Romans during the decline of the empire. In the 5th century the territory was conquered by the Burgundians, and formed part of their kingdom; nearly a hundred years later it was occupied by the Franks. It was included in Charlemagne's empire and was divided by him into counties, which evolved there, as elsewhere, into hereditary fiefs; but after the break-up of Charlemagne's empire, the Burgundian kingdom revived and Savoy was again absorbed in it. After the collapse of that monarchy its territories passed to the German kings, and Savoy was divided between the counts of Provence, of Albon, of Gex, of Bresse, of the Genevois, of Maurienne, the lords of Habsburg, of Zähringen, etc., and several prelates.

Early Counts.—The founder of the house of Savoy was Umberto Biancamano (Humbert the White-handed), a feudal lord, who in 1003 was count of Salmourenc in the Viennois, in 1017 of Nyon on the Lake of Geneva, and in 1024 of the Val d'Aosta on the eastern slope of the Western Alps. In 1034 he obtained part of Maurienne as a reward for helping King Conrad the Salic to make good his claims on Burgundy. He also obtained the counties of Savoy, Belley, part of the Tarantaise, and the Chablais. With these territories Umberto commanded three of the great Alpine passes, viz., the Mont Cenis and the two St. Bernards. His son Oddone married Adelaide, eldest daughter and heiress of Odelrico Manfredi, marquess of Susa, a descendant of Arduino of Ivrea, king of Italy, who ruled over the counties of Turin, Auriate, Asti, Bredulo, Vercelli, etc., corresponding roughly to modern Piedmont and part of Liguria (1045). Umberto died some time after 1056 and was succeeded by his son, Amadeus I., at whose death the country passed to Oddone. Oddone ruled over territories on both sides of the Alps. He died in 1060, and was succeeded by his widow, Adelaide; but before her death in 1091 his son, Peter I., became count, and subsequently the latter's brother, Amadeus II. Under Humbert II. (1080) occurred the first clash with the Piedmontese communes, but he and his successors, Amadeus III. (who died on his way home from the crusades) and Thomas I. (1189), adopted a policy of conciliation towards them.

Thomas, who reigned until 1222, acquired extensions of territory in the Bugey, Vaud and Romont to the west of the Alps, and Carignano, Pinerolo, Moncalieri and Vigone to the east; he also exercised sway over Geneva, Albenga, Savona and Saluzzo. At his death these territories were divided among his sons, Thomas II. obtaining Piedmont, Aimone the Chablais, Peter and Philip other fiefs, and Amadeus IV., the eldest, Savoy and a general overlordship over his brothers' estates. Thomas II., during the wars in Piedmont, was made prisoner by the citizens of Turin, but was afterwards liberated.

Amadeus V. (1285–1323), son of Thomas II., reunited the county of Savoy (his own territory), the principality of Piedmont, ruled by his nephew Philip, prince of Achaea (a title acquired through his wife, Isabella of Villehardouin, heiress of Achaea and the Morea), and Vaud, ruled by his brother Louis. But although this division was formally recognized in 1295. Amadeus succeeded in enforcing his own supremacy over the whole country and in regaining by war, purchase or treaty, the fiefs lost by his predecessors. He fought against the dauphins of Viennois, the counts of Genevois, the people of Sion and Geneva, the marquesses of Saluzzo and Montferrat, and the barons of Faucigny, acted as peacemaker between France and England, accompanied the Emperor Henry VII. of Luxemburg on his expedition to Italy, reorganized the finances of the realm and reinforced the Salic law of succession. He was succeeded by his sons, Edward (1323–1329), known as "the Liberal," on account of his extravagance, and Aimone, the Peaceful (1329–1343), who strove to repair the harm done to the state's exchequer by his predecessor and proved one of the best princes of his line.

Amadeus VI. (1343–1383), son of Aimone, the Peaceful, and known as the *Conte Verde* or Green Count because of the costume he habitually wore at tourneys, succeeded at the age of nine. He won a reputation as a bold knight in the fields of chivalry and inaugurated a new policy by devoting more attention to his Italian possessions than to those on the French side of the Alps and in Switzerland. In 1366 he led an expedition to the East against the Turks; and he arbitrated between Milan and the house of Montferrat (1379), between the Scaligeri and the Visconti, and between Venice and Genoa after the "War of Chioggia" (1381). Amadeus was the first sovereign to introduce a system of gratuitous legal assistance for the poor. He espoused the cause of Louis, duke of Anjou, and while aiding that prince in his attempt to recover the kingdom of Naples he died of the plague, leaving his realm to his son, Amadeus VII., the *Conte Rosso* or "Red Count" (1383–1391); the latter added Nice (1388) and other territories to his domains.

Amadeus VIII. (1391–1451), count, extended his territories both in Savoy itself and in Italy, and in 1416 was created duke by the emperor Sigismund. In 1430 he promulgated a general

GENEALOGICAL TABLE OF THE HOUSE OF SAVOY.

Humbert the Whitehanded (Umberto Biancamano) (d. after 1056).

Amadeus I. (d. c. 1056).
Odonne or Otto = Adelaide, heiress of Turin (d. 1091)

Peter I. (d. 1078).
Amadeus II. (d. 1080).
Bertha = Emperor Henry IV.

Humbert II. the Fat (d. 1103).

Amadeus III. (d. 1148 or 1149).
Alice or Adelaide = Louis VI. of France.

Humbert III. the Saint (d. 1189).

Thomas I. (d. 1222).

Amadeus IV. (d. 1253).
Boniface (d. 1263).
Peter II., earl of Richmond (d. 1268).
Philip I. (d. 1285).
Thomas II., count of Piedmont (d. 1259).
Boniface, archbishop of Canterbury (d. 1270).

Louis I. of Vaud (d. 1302.)
Amadeus V. the Great (d. 1323).
Thomas III. (d. 1282).

Edward the Liberal (d. 1329).
Aimone the Peaceful (d. 1343).
Anne = the eastern emperor, Andronicus III.
Philip, prince of Achaea (d. 1334).

Amadeus VI. (d. 1383).
James (d. 1367).

Amadeus VII. (d. 1391).
Amadeus (d. 1402).
Louis (d. 1418).

Amadeus VIII., first duke of Savoy, afterwards Pope Felix V. (d. 1451).

Louis (d. 1465).
Philip, count of Geneva (d. 1444).

Amadeus IX. (d. 1472).
Philip II. (d. 1497).
Louis, king of Cyprus (d. 1482).

Philibert I. (d. 1482).
Charles I. (d. 1490).
Charles II. (d. 1496).
Philibert II. (d. 1504).
Charles III. (d. 1553).
Philip, founder of the house of Nemours (d. 1533).
Louise = Charles, count of Angoulême
Francis I. of France.

Emmanuel Philibert (d. 1580).

Charles Emmanuel I. (d. 1630).

Victor Amadeus I. = Christina, daughter of Henry IV. of France (d. 1637).
Thomas Francis, prince of Carignano (d. 1656).

Francis Hyacinth (d. 1638).
Charles Emmanuel II. (d. 1675).
Emmanuel Philibert (d. 1709).
Eugene Maurice count of Soissons (d. 1673).

Victor Amadeus II. (d. 1732). KING OF SARDINIA, 1720; abdicated 1730 = Anne of Orleans, granddaughter of Charles I. of England.
Victor Amadeus (d. 1741).
Eugene, the famous general (d. 1736).

Charles Emmanuel III. (d. 1773).
Louis Victor (d. 1778).

Victor Amadeus III. (d. 1796).
Victor Amadeus (d. 1780).

Charles Emmanuel (d. 1800).

Charles Emmanuel IV. (d. 1819); abdicated 1802.
Victor Emmanuel I. (d. 1824); abdicated 1821.
Charles Felix (d. 1831).
Charles Albert (d. 1849). King of Sardinia; abdicated 1849.

Victor Emmanuel II. (d. 1878). KING OF ITALY, 1861.
Ferdinand, duke of Genoa (d. 1855).

Humbert (d. 1900), king of Italy = Margherita of Savoy-Genoa
Amadeus (d. 1890), duke of Aosta. King of Spain, 1870–73.
Clothilde = Prince Napoleon (d. 1891).
Maria Pia (b. 1847) = Louis, king of Portugal.
Margherita = Humbert, king of Italy.
Thomas duke of Genoa (b. 1854).

Victor Emmanuel III., king of Italy (b. 1869) = Elena of Montenegro (b. 1873).
Emmanuel Philibert, duke of Aosta (b. 1869).
Victor Emmanuel, count of Turin (b. 1870).
Louis Amadeus, duke of the Abruzzi (b. 1873).
Humbert, count of Salemi (b. 1889).

Yolanda Margherita (b. 1901).
Mafalda (b. 1902).
Humbert, prince of Piedmont, heir to the throne (b. 1904).
Giovanna (b. 1907).
Maria (b. 1914).
Amadeus, duke of Puglia (b. 1898).
Aimone, duke of Spoleto (b. 1900).
Ferdinand, prince of Udine (b. 1884).
Philibert, duke of Pistoia (b. 1895).
Maria Bona Margherita (b. 1896).
Adalbert, duke of Bergamo (b. 1898).
Eugene (b. 1906).

statute of laws for the whole duchy, in spite of the opposition of the nobles and cities whose privileges were thereby curtailed. In 1434 he retired to the hermitage of Ripaille on the Lake of Geneva, but continued to conduct the chief affairs of the State and to mediate between foreign Powers, leaving matters of less importance to his son Louis. Five years later the council of Basel elected Amadeus pope, in spite of his not being a priest, and deposed Eugenius IV. Amadeus accepted the dignity, assuming the style of Felix V. (*q.v.*). In 1449 Amadeus abdicated and returned to his hermitage at Ripaille, where he died two years later. (*See* FELIX V.)

15th Century.—Under Louis, Savoy began to decline, for he was indolent, incapable, and ruled by his wife, Anne of Lusignan, daughter of the king of Cyprus, who induced him to fit out an expedition to Cyprus, which brought him no advantage save the barren title of king of Cyprus, Jerusalem and Armenia. He went to France to seek aid of King Louis XI. against his nobles, and died there in 1465. In spite of his incapacity he acquired the city of Freiburg and the homage of the lords of Monaco. He was succeeded by his son, Amadeus IX. (1455–1472), who on account of ill-health left the duchy in the hands of his wife, Yolande, sister of Louis XI. During the minority of his son Philibert I. (1472–1482) Savoy lost Freiburg and many other territories. Philibert was succeeded by his brother Charles I. (1482–1490), who, freed by Louis XI. from the dangerous protection of Philip of Bresse and by death from that of the French king, crushed the rebellious nobles and seized Saluzzo (1487). He did much to raise the fortunes of his house, but died at the age of 31. Under his successors the duchy lost ground until the accession of Emmanuel Philibert in 1553.

Emmanuel Philibert.—At the time of his accession, Emmanuel Philibert was serving in the Spanish armies. Emmanuel could not take possession of the duchy at once, but continued to serve the emperor as governor-general of the Low Countries. By his victory at St. Quentin over the French in 1557 he proved himself one of the first generals of the day, and by the terms of the subsequent treaty of Cateau Cambrésis he was reinstated in most of his hereditary possessions (1559). Under Emmanuel Philibert Savoy lost all traces of constitutional government and became an absolute despotism of the type then predominating throughout the greater part of Europe. At the same time he raised his country from ruin and degradation into a prosperous and powerful monarchy.

Charles Emmanuel I.—His son and successor, Charles Emmanuel I. (*q.v.*), surnamed the Great, strengthened the tendency of Savoy to become less of a French and more of an Italian Power. In 1588 he wrested Saluzzo from the French, but his expeditions to Provence and Switzerland were unsuccessful. In the war between France and Spain after the accession of Henry IV., he took the Spanish side, and at the peace of Lyons (1601), although he gave up all his territories beyond the Rhone, his possession of Saluzzo was confirmed. His attempt to capture Geneva by treachery (1602) failed, and although on the death of Francesco Gonzaga, duke of Mantua and Montferrat, he seized the latter city (1612) he was forced by Spain and her allies to relinquish it. The Spaniards invaded the duchy, but after several years of hard fighting the peace of 1618 left his territory almost intact. In 1628 he sided with Spain against France; the armies of the latter overran the duchy, and Charles Emmanuel died in 1630. (*See* CHARLES EMMANUEL.) His son, Victor Amadeus I. (1630–1637), succeeded to little more than a title, but by his alliance with France —his wife, Christina, being a daughter of Henry IV.—he managed to regain most of his territories. He proved a wise and popular ruler, and his early death was much deplored. He was succeeded by his second son, Charles Emmanuel II., who, being a minor, remained under the regency of his mother. That princess, in spite of her French origin, resisted the attempts of France, then dominated by Cardinal Richelieu, to govern Savoy, but her quarrels with her brothers-in-law led to civil war, in which the latter obtained the help of Spain, and Christina that of France. In the end the duchess succeeded in patching up these feuds and saving the dynasty, and in 1648 Charles Emmanuel II. assumed the government. The war between France and Spain continued, and Savoy, on whose territory much of the fighting took place, suffered severely in consequence. By the treaty of the Pyrenees (1669) Savoy regained most of the towns occupied by France.

Victor Amadeus II.—Charles died in 1675 and was succeeded by his only son, Victor Amadeus II. (*q.v.*). The French king's arrogant treatment of Victor Amadeus spurred the latter to join the league of Austria, Spain and Venice against him in 1690. The campaign was carried on with varying success, but usually to the advantage of Louis, and the French victory at Marsiglia and the conduct of the allies induced Victor to come to terms with France (1696). By the treaty of Ryswick a general peace was concluded. In the War of the Spanish Succession (1700) Victor fought on the French side, until, dissatisfied with the continued insolence of Louis XIV. and of Philip of Spain, he went to the Austrians in 1704. The French invaded Piedmont, but were totally defeated at the siege of Turin by Victor Amadeus and Prince Eugene of Savoy (1706), and eventually driven from the country. By the treaty of Utrecht (1713) Victor received the long-coveted Montferrat and was made king of Sicily; but in 1718 the powers obliged him to exchange that kingdom for Sardinia, which conferred on the rulers of Savoy and Piedmont the title subsequently borne by them until they assumed that of kings of Italy. In 1730 he abdicated in favour of his son, Charles Emmanuel.

Charles Emmanuel III.—Charles Emmanuel III. (1730–1773), a born soldier, took part in the War of the Polish Succession on the side of France against Austria, and for his victory at Guastalla (1734) was awarded the duchy of Milan, which, however, he was forced to relinquish at the peace of Vienna (1736), retaining only Novara and Tortona. In the War of the Austrian Succession, which broke out on the death of the Emperor Charles VI., he took the side of Maria Theresa (1742). By the peace of Aix-la-Chapelle in 1748, following on the defeat of the French, Savoy gained some further accessions of territory in Piedmont. The reign of Charles's son, Victor Amadeus III. (1773–1796), was a period of decadence; the king was incapable and extravagant, and he chose equally incapable ministers. On the outbreak of the French Revolution he sided with the royalists and was eventually brought into conflict with the French republic. The army being demoralized and the treasury empty, the kingdom fell an easy prey to the republican forces. Savoy became a French province, and, although the Piedmontese troops resisted bravely for four years in the face of continual defeats, Victor at last gave up the struggle and signed the armistice of Cherasco. On his death in 1796, he was succeeded in turn by his three sons, Charles Emmanuel IV., Victor Emmanuel I. and Charles Felix.

Charles Emmanuel IV.—Charles Emmanuel (1796–1802), believing in Bonaparte's promises, was induced to enter into a confederation with France and give up the citadel of Turin to the French, which meant the end of his country's independence. Realizing his folly he abdicated on Dec. 6, 1796, and retired to Sardinia, while the French occupied the whole of Piedmont. After the defeat of the French by the Austro-Russian armies during Bonaparte's absence in Egypt, Charles Emmanuel landed at Leghorn, hoping to regain his kingdom; but Napoleon returned, and by his brilliant victory at Marengo he reaffirmed his position in Italy. The king retired to Naples, abdicated once more (1802), and entered the Society of Jesus; he died in Rome in 1819. Victor Emmanuel I. (1802–1820) remained in Sardinia until by the Final Act of the Congress of Vienna (June 9, 1815) his dominions were restored to him, with the addition of Genoa.

Italian Allegiance.—From this time the fortunes of the house of Savoy are bound up with those of Italy. (*See* ITALY: *History.*) Victor Emmanuel I. abdicated in 1821 in favour of his brother Charles Felix (1821–1831). The latter being without a son, the succession devolved upon Charles Albert, of the cadet line of the princes of Carignano, who were descended from Thomas, youngest son of Charles Emmanuel I. Charles Albert abdicated, on the evening of his defeat at Novara (April 20, 1849), in favour of his son Victor Emmanuel II. (1849–1878), who on Feb. 18, 1861, was proclaimed king of Italy. Victor

Emmanuel had married in 1842 Maria Adelaide, daughter of the archduke Rainer, who bore him several children, viz., Princess Clothilde (b. 1843), who married Prince Napoleon; Humbert (*q.v.*), who succeeded him; Amadeus, duke of Aosta (b. 1845); Oddone, duke of Montferrat (b. 1846); and Princess Maria Pia (b. 1847). Humbert was succeeded by his only son, Victor Emmanuel III. (*q.v.*).

The second son of Victor Emmanuel II., Amadeus, duke of Aosta, was offered the crown of Spain by the Cortes in 1870, which he accepted, but, finding that his rule was not popular, he abdicated in 1873 rather than cause civil war. In 1867 he married Princess Maria Vittoria dal Pozzo della Cisterna, who bore him three sons, viz., Emmanuel Philibert, duke of Aosta (b. 1869), Victor Emmanuel, count of Turin, and Louis Amadeus, duke of the Abruzzi, an Italian naval officer and a distinguished traveller, explorer and man of science. The first wife of Amadeus, duke of Aosta, having died in 1876, he married Princess Maria Letizia Bonaparte in 1888, who bore him a son, Humbert, count of Salemi (b. in 1889). (L. V.)

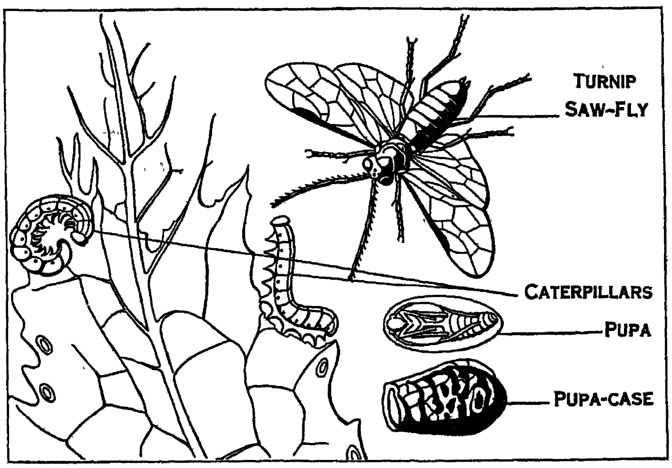
SAWANTWARI: *see* SAVANTVADI.

SAW-FLY, the name given to members of the division Symphyta of the order Hymenoptera (*q.v.*), characterized by the broad base to the abdomen, where it joins the thorax, and by the wing-veins being less reduced than in other members of the order. Their name is derived from the fact that the lower or anterior blades of the ovipositor are toothed and saw-like. Their larvae are usually caterpillars and in most cases may be distinguished from those of moths and butterflies by having six or more pairs of abdominal feet and only a single pair of simple eyes or ocelli. When disturbed they roll themselves in a spiral fashion and some species discharge a thin fluid from glands above the spiracles. The females lay their eggs in incisions in plants, cut by the saw-like blades of the ovipositor, and the larvae are vegetable feeders. Species of several genera, notably *Pontania,* form galls on willows.



THE LIFE HISTORY OF THE TURNIP SAW-FLY (ATHALIA SPINARUM)

The cause of the gall is stated to be a secretion injected along with the egg, and it has been suggested that it contains an enzyme which acts upon the plant so as to induce gall-formation. Reproduction in saw-flies is of considerable interest: in many species males are unknown and parthenogenesis (*q.v.*) is the rule. In the gooseberry saw-fly the unfertilized eggs give rise only to males, while the fertilized eggs produce individuals of both sexes, females predominating.

The true saw-flies belong to the large family *Tenthredinidae* and the larvae of many of these are injurious to plants. Thus, the gooseberry saw-fly, *Nematus ribesii,* is very destructive to that plant and to currants, while the pear slug, *Caliroa limacina,* attacks pears. These two species and also the larch saw-fly, *Lygaeonematus erichsonii,* have been accidentally imported from Europe into North America where they have likewise become destructive. Other harmful species in Europe are *Athalia spinarum,* the turnip saw-fly, and *Lophyrus pini,* which attacks plantations of Scotch firs. The best remedy is to shake off and destroy the young larvae from bushes, where practicable, or to spray with an arsenical wash. The small families *Cephidae* and *Siricidae* have larvae that are borers. The *Cephidae* include the stem saw-flies, and the best-known species is *Cephus pygmaeus,* which attacks wheat. Although seldom causing appreciable injury in Britain it is destructive in North America, where *Janus integer,* the stem-girdler of the currant, is also troublesome. The *Siricidae* bore into solid timber and are known as wood-wasps or horn-tails. *Sirex gigas* is the most familiar European wood-wasp and is not uncommon in Britain. (A. D. I.)

SAWING MACHINES. The saw is one of the most valuable tools, and just as there are many varieties of hand-saws so there are many machines, suited for sawing wood, bone, fibre, stone, marble, slate and metals, and varying in size from little fret-sawing machines to the huge machines which part off steel ingots with a 12 ft. diameter circular saw.

There are three methods of action; the reciprocating blade, cutting one way or both ways, the continuously running blade or band-saw, and the circular saw. Some materials can be cut on any system without making any real difference to the results, but often it happens that one method proves better than another. The shape to be parted off or cut to outline may be difficult or impossible with one sort of blade and easy with another, while size makes a difference in some cases. Thin saws penetrate with less consumption of power, and are the choice if they will cut truly instead of deviating. Moreover, there is less waste of material in the form of dust, an important consideration in the more expensive substances. Yet if a thin saw wanders from a true line it may not be economical, by reason of the fact that the cut surface has to be trued up afterwards with more or less expenditure of time and labour. Wood cutting saws are dealt with under WOODWORKING MACHINERY.

Machines with Reciprocating Blades.—The smallest machines of this class are the *jig-saws,* equivalents of the fret-saws for wood. The work is held upon a horizontal table up through which the saw blade reciprocates, with a stroke variable from zero to three or four inches in the smallest sizes. Dies, metal patterns and templates of intricate outline are sawn out of sheets or blocks. The reciprocation is produced by a belt pulley driving a crank-disc and connecting-rod. Some machines have holders which will grip a file instead of a saw so as to finish outlines smoothly after sawing, and an oil-stone stick or lap may also be used for truing up hardened dies.

A larger type of machine is the power hack-saw, which has a horizontal frame to strain the blade in like a hand hack-saw; it reciprocates the blade with crank and rod over a vice in which the bar or girder to be sawn is clamped. The weight of the frame is sufficient to feed the blade through, and a safety arrangement takes care of the possibility of the blade snapping as it breaks through the bar. Multiple-blade machines cut off a number of discs or slabs simultaneously, and rather big machines are now made for girder sawing. Portable machines are used for sawing tram and railway rails and girders. The hack-saw is a cheap and handy machine for any class of workshop, large or small, and the blades are cheap and quickly replaced. Until recently they were thrown away when worn too dull for efficient cutting, but now tungsten blades of fast cutting capacity can be sharpened many times.

Band-Sawing Machines.—Wide cuts are taken in wood with reciprocating saws that deal with logs, and stone-sawing machines are also built on the same principle; a long table carrying the wood or stone along under the blade, but this is

not suitable for thick metal-cutting. The band-saws cut faster, with better guidance, and the dust is carried away more effectually. These machines are either vertical or horizontal. In the former design the metal is clamped to a horizontal table and the blade runs over a top pulley and down through the work and table to the lower pulley. Straight or curved cuts are controlled by the movements of the table by handles and screws operating slides. Though small machines are occasionally used instead of the jig-saws, most band-saws are of fairly large dimensions, with pulleys from 3 ft. to about 6 ft. in diameter, the latter size admitting slabs or forgings of nearly 6 ft. in depth. The pulleys are covered with rubber tyres to give the grip to the saw, and in cutting iron and steel a soapy water solution has to be pumped on to the blade. This is run through a guide immediately above the surface of the work to assist in true cutting. Horizontal band-saws of large dimensions deal with forgings, fed along by a table as in a planing-machine, and are also very convenient for trimming off the uneven edges of flanged plates, for boiler construction, enabling the caulking to be done properly after riveting together.

Circular Sawing Machines.—These comprise a large group, from little ones to saw bone, fibre, aluminium, brass and copper, to the more powerful types that cut iron and steel. The speeds of rotation of the saws for the soft materials are high, and the feeding can often be effected by hand instead of by slides or levers such as are necessary in steel and iron sawing. Sometimes it is the saw that is fed along by a slide, sometimes the work on a slide instead. The machines which cut girders have a special yielding motion to the feed device: this causes the saw to feed more slowly through the thick sections than through the thin webs, which can naturally be penetrated at a faster rate. The saw is clamped on a spindle with nut and washer for ordinary cutting, but the *flush-side* machines have the saw attached with sunken bolts, so that one side of it is perfectly flat. This provision is essential for iron and steel foundries, to part off the superfluous runners or gates (which feed the molten metal into the mould) flush with the surface.

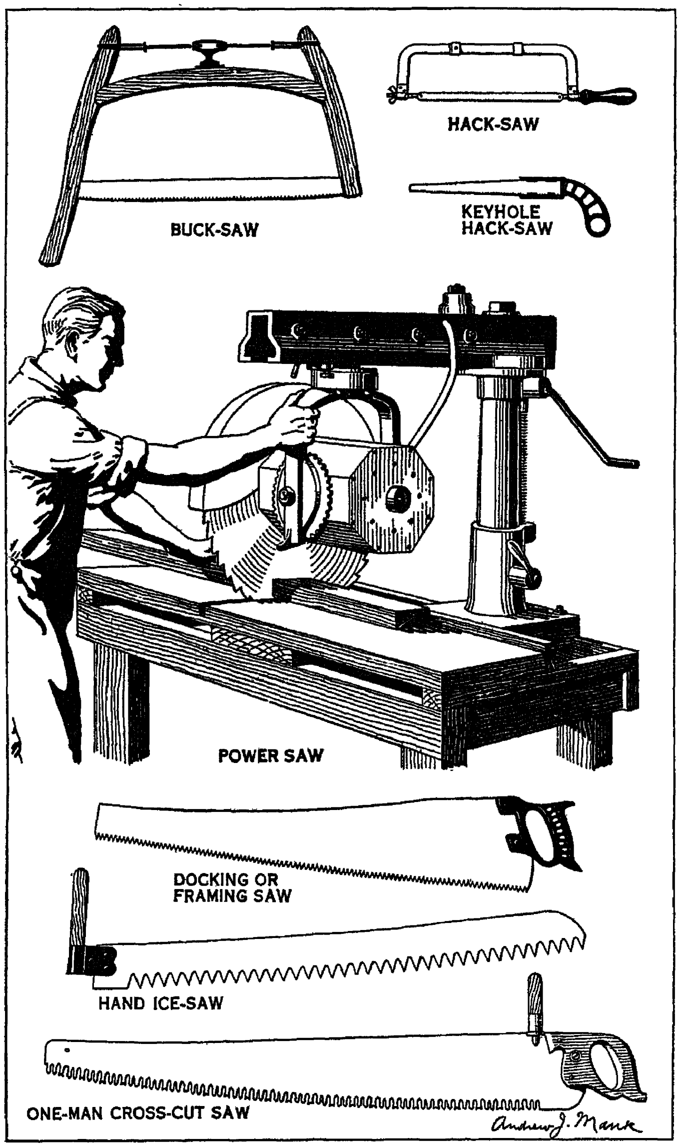
Ordinary saw blades are formed with the teeth cut in the same disc, but the larger blades, especially for steel forging sawing, have inserted teeth, each held in with a wedge and screw fastening, so that any breakages can be made good cheaply and quickly. The largest blades cut armour-plate and ingots, also pieces out of big crankshaft forgings to form the webs. Duplex blades, running side by side at the appropriate distance apart halve the time of cutting out such slabs.

In the iron and steel works hot metal during forging or rolling operations is parted by a special sort of machine, the *hot saw,* that cuts at a fast rate. The large machines act on the pendulum principle, the blade being run in bearings at the bottom end of a deep swing frame which is pushed across by hydraulic or pneumatic cylinder to pass the saw through the hot metal, resting on a slideway beneath. The speed of revolution is high, and large horse-power is consumed.

Friction Sawing Machines.—These are peculiar inasmuch as the circular blade has no cutting teeth, but is driven at so high a speed that the friction generates such heat in the immediate vicinity that the metal is burned through. For instance a railway rail of 90 lb. per yard can be parted off in 7 seconds, or a channel section of 12 in. by 6 in. with $\frac{3}{4}$ in. thick metal in 14 seconds, leaving a clean smooth finish. Some assistance is given to the action if the blade is very slightly notched around the periphery, though not like the true teeth of a saw. (F. H.)

SAW-MILL, strictly, a mill in which logs are "broken down" into balks, deals, flitches, battens, planks and boards for sale or further treatment. But often the word is applied to a mill the plant of which includes planing, moulding, tenoning and other machines for finishing processes. The biggest mills are usually situated near a timber supply, brought by river or rail, and the design of the mill is in some degree affected by the mode of transit. More space is necessary for storage in the rail-borne example. In the water-borne system the logs float right into the mill and are dragged out in turn by a winch. An overhead crane serves the stock-yard in the rail system, and carries the logs on to the machines.

The cutting is performed on various kinds of big machines, a preliminary operation often being that of cross-cutting to obtain convenient lengths. Cutting up into the various thicknesses is done by either reciprocating or band-saws, or circular saws, the log being held with dogs on a table which feeds it past the saw. Some band-sawing machines are of horizontal design, some vertical, the latter taking up less floor-space. The log-frame is a machine with a set of vertically reciprocating blades, suitably spaced apart, and it divides a log into boards at one pass of the table. The number of blades may be few, not exceeding four in some cases for cutting thick pieces, or as many as fifty for thin boards. Re-sawing machines are those for further dealing with material partly broken up, such as flitches and deals. The great quantity of sawdust and chips from the machines is neatly disposed of by pneumatic ducts ending in the boiler house, on the system mentioned in FANS.



POWER SAW BY COURTESY OF THE DE WALT PRODUCTS CO.; OTHERS BY COURTESY OF THE SIMONDS SAW AND STEEL CO.

TYPES OF SAWS WITH A MOTOR-DRIVEN WOODWORKER SAW IN THE CENTRE

SAWS, cutting-tools with toothed edges. The various types of saw may be classified into reciprocating, revolving, and travelling, *i.e.,* band-saws passing around wheels. The first class includes numerous hand- and machine-operated blades, some cutting only on the one stroke, others cutting both backwards and forwards. The second class covers the circular saws for wood,

bone, ivory and metal; the largest of the third class are made up to about 12 ft. in diameter. Large band-saws are used for cutting up big forgings into various outlines. Some saws have the teeth milled or punched out of the solid plate or web; others have teeth fastened in with wedges, so that they are easily replaced in case of fracture, besides being easier to make and temper. What are termed *friction saws* have either no teeth or but slight notches on the periphery, and they will cut through iron and steel owing to the heat generated by the friction at the great speed of rotation. Diamond saws have a large number of diamonds fixed in pockets on the rim and are employed for stone sawing. The principal difficulties with saws are clearance in the "kerf," which depends on the "set" or side projection of the teeth beyond the web or plate of the saw; and true cutting, which depends partly on guidance and partly on the truth of the blade. Circular saws for wood are hammered to make a "tension," so that although the saw does not lie true while at rest, its rim runs perfectly true at the appropriate speed for which it has been tensioned.

Saws date from Neolithic times, when they were formed from flint flakes with finely jagged edges; they were followed by metal saws made in bronze or copper. Now steel is employed exclusively, some for sawing wood being tempered soft enough to be sharpened with a file, while those for cutting metal can only be sharpened with a grinding wheel. The fineness or coarseness of teeth varies greatly, according to the class of sawing. So do the shapes of teeth, some pointing forward with straight or curved edges, others of equal angles and many of special *M* shapes for heavy cross-cutting of lumber. The most elaborate teeth have "cleaner" teeth interspaced so as to scrape out the sawdust and clean the kerf neatly. In the larger circular saws the inserted class of teeth is very common. These are held in pockets around the disc with a *V* fastening and a springy holder, or with a wedge fixing. (*See* WOODWORKING MACHINERY; MACHINE TOOLS.)

SAWTREY, WILLIAM (d. 1401), English Lollard, was a priest at Lynn who was summoned before the bishop of Norwich for heresy in 1399. He was the first Lollard martyr, being burned at St. Paul's Cross in March 1401.

SAX, ANTOINE JOSEPH, known as ADOLPHE (1814–1894), maker of musical instruments, was born at Dinant in Belgium on Nov. 6, 1814, and died in Paris in 1894. In 1835 he perfected a bass clarinet superior to any that had preceded it. He went to Paris in 1842, and set up a workshop in the Rue St. Georges. Sax discovered a new principle in the manufacture of wind instruments, viz., that it is the proportions given to a column of air vibrating in a sonorous tube, and these alone, that determine the character of the timbre produced: the material of the walls of the tube is not of the slightest importance so long as it offers enough resistance. In 1845 he patented his saxhorn and a family of cylinder instruments called saxotrombas. On June 22, 1846 he registered the saxophone. He also effected various improvements in piston instruments, of which the most important was the substitution of a single ascending piston for a number of descending ones.

See J. P. O. Cornettant, *Histoire d'un inventeur* (1860); C. Pilard, *Les Inventions Sax* (1869).

SAXA RUBRA, also called AD RUBRAS (rupes, *i.e.*, the red tufa cliffs) a post-station on the ancient Via Flaminia, 9m. north of Rome. The modern hamlet of Prima Porta takes its name from the remains of a brick arch, perhaps of Constantine period. It was the site of the defeat of Maxentius by Constantine in A.D. 312 in the decisive battle which sealed the triumph of Christianity (*see* CONSTANTINE I.). This is often known as the battle of the Milvian bridge, from the fact that Maxentius and many of his routed troops were drowned there. That Constantine's headquarters were at Malborghetto has been proved by Toebelmann.

See F. Toebelmann, *Der Bogen von Malborghetto* (Heidelberg, Akademie der Wissenschaften, Abhandlung, philosophisch-historische Klasse, 1915); T. Ashby and R. A. L. Fell in *Journal of Roman Studies XI.* (1921); G. Lugli in Bollettino Communale (1923); T. Ashby, *The Roman Campagna in Classical Times*, chap. xii. (1927).

SAXE, JOHN GODFREY (1816–1887), American poet, humorist and editor, was born at Highgate, Vt., June 2, 1816. He was best known as a writer of humorous verse and a lecturer. Some of his lyrics have genuine feeling as well as grace. His "Rhyme of the Rail," "The Proud Miss McBride," "I'm Growing Old" and "Treasures in Heaven" were once very popular. Among his published collections are *Humorous and Satirical Poems* (1850), *The Times, The Telegraph, and other Poems* (1865), and *Leisure Day Rhymes* (1875). He died at Albany, N. Y., March 31, 1887.

SAXE, MAURICE, COMTE DE (1696–1750), marshal of France, was the natural son of Augustus II. of Saxony and the countess Aurora Königsmarck. In 1698 the countess sent him to Warsaw to his father, who had been elected king of Poland in the previous year, but on account of the unsettled condition of the country the greater part of his youth was spent outside its limits. He served under Prince Eugène in the Netherlands, and under Peter the Great against the Swedes. After receiving in 1711 formal recognition from his father, with the rank of count, he accompanied him to Pomerania, and in 1712 he took part in the siege of Stralsund. In manhood he bore a strong resemblance to his father, both in person and character. His grasp was so powerful that he could bend a horse-shoe with his hand, and to the last his energy and endurance were scarcely subdued by the illnesses resulting from his many excesses. In 1714 he married a rich wife, Johanna Victoria, countess von Loeben, but he dissipated her fortune so rapidly that he was soon heavily in debt, and the marriage was annulled in 1721. Meantime, after serving in a campaign against the Turks in 1717, he had in 1719 gone to Paris, to study mathematics, and in 1720 obtained a commission as *maréchal de camp*. In 1725 negotiations were entered into for his election as duke of Courland, at the instance of the duchess Anna Ivanovna, who offered him her hand. He was chosen duke in 1726, but declining marriage with the duchess found it impossible to resist her opposition to his claims, although, with the assistance of £30,000 lent him by the French actress Adrienne Lecouvreur, he raised a force by which he maintained his authority till 1727, when he withdrew and took up his residence in Paris. On the outbreak of the war in 1734 he served under Marshal Berwick, and for a brilliant exploit at the siege at Philippsburg he was in August named lieutenant-general. On the opening of the Austrian Succession War in 1741, he took command of a division of the army sent to invade Austria, and on Nov. 19 surprised Prague during the night, and took it by assault before the garrison were aware of the presence of an enemy. After capturing the fortress of Eger on April 19, 1742, he received leave of absence, and went to Russia to push his claims on the duchy of Courland, but obtaining no success he returned to his command. His exploits had been the sole redeeming feature in an unsuccessful campaign, and on March 26, 1743, he was promoted to be marshal of France.

Marshal Saxe was now one of the first generals of the age. In 1744 he was chosen to command the expedition to England on behalf of the Pretender, which assembled at Dunkirk but did not proceed farther. After its abortive issue he received an independent command in the Netherlands, and by dexterous manoeuvring succeeded in continually harassing the superior forces of the enemy without risking a decisive battle. In the following year he besieged Tournai and inflicted a severe defeat on the relieving army of the duke of Cumberland at Fontenoy (*q.v.*). Thenceforward to the end of the war he continued to command in the Netherlands, always with success. Besides Fontenoy he added Rocoux (1746) and Lawfeldt or Val (1747) to the list of French victories, and it was under his orders that Marshal Löwendahl captured Bergen-op-Zoom. He himself won the last success of the war in capturing Maestricht in 1748. In 1747 the title formerly held by Turenne, "Marshal general of the King's camps and armies," was revived for him. But on Nov. 30, 1750, he died at Chambord.

In 1748 there had been born to him a daughter, one of several illegitimate children, whose granddaughter was George Sand. Saxe was the author of a remarkable work on the art of war, *Mes Rêveries*, which though described by Carlyle as "a strange military farrago, dictated, as I should think, under opium," is in fact a classic. It was published posthumously in 1757 (ed

Paris, 1877).

Suivie d'une correspondence inédite de Maurice de Saxe pendant cette campagne* (1909), which contains a full bibliography.

SAXE-ALTENBURG. The district later forming the duchy of Saxe-Altenburg came into the possession of the margrave of Meissen about 1329, and later with Meissen formed part of the electorate of Saxony. In 1603 Saxe-Altenburg was made into a separate duchy, but this only lasted until 1672. In 1825 it again became a separate duchy under Frederick, previously Duke of Saxe-Hildburghausen. His family's reign was terminated by the German revolution of 1918.

SAXE-COBURG-GOTHA, formerly a sovereign duchy of Germany and a constituent member of the German empire, and since 1918 amalgamated into Thuringia. (*See* THURINGIA and BAVARIA.)

History.—The district of Coburg came into the possession of the family of Wettin in the 14th century, and after the Wettins had become electors of Saxony this part of their lands fell at the partition of 1485 to the Ernestine branch of the house. From that time onwards Coburg, Gotha and Saalfeld were frequently partitioned and repartitioned until 1826, when Ernest, duke of Saxe-Coburg-Saalfeld, exchanged Saalfeld for Gotha, took the title of duke of Saxe-Coburg-Gotha and became the founder of the house which ruled until the revolution of 1918. On the death of Ernest II. in 1893 the succession passed to the children of his brother Albert, the English prince consort, whose son Prince Alfred reigned from 1893 to 1900, and was succeeded by his nephew Charles Edward, duke of Albany, the last reigning duke.

SAXE-MEININGEN, a former grand duchy of Germany, and since 1918 amalgamated into Thuringia (*q.v.*).

History.—The Duchy of Saxe-Meiningen, or more correctly Saxe-Meiningen-Hildburghausen, was founded in 1681 by Bernard, the third son of Ernest the Pious, duke of Saxe-Gotha, and consisted originally of the western part of the later duchy, the district around Meiningen.

By the rearrangement of the Saxon duchies in 1826, Saxe-Meiningen benefited greatly, its area being more than doubled by the receipt of 530sq.m. of territory. The additions consisted of the duchy of Saxe-Hildburghausen, the duchy of Saxe-Saalfeld, which had been united with Saxe-Coburg in 1735; and the districts of Themar, Kranichfeld and Kamburg. Saxe-Meiningen became a member of the new German empire in 1871. In 1918 the ruling family lost its power in the general revolution.

SAXE-WEIMAR-EISENACH, formerly a grand duchy of Germany and a sovereign and constituent State of the German empire, and since 1918 amalgamated into Thuringia (*q.v.*).

History.—In early times Weimar and district belonged to the counts of Orlamünde, and from the end of the 10th century until 1067 it was the seat of the counts of Weimar. In the 14th century it passed to the elector of Saxony, falling at the partition of 1485 to the Ernestine branch of the Wettin family. It was not until 1641 that Saxe-Weimar emerged into an independent historical position. In this year, having just inherited Coburg and Eisenach, the three brothers William, Albert, and Ernest founded the three principalities of Saxe-Weimar, Saxe-Eisenach, and Saxe-Gotha. Eisenach fell to Saxe-Weimar in 1644, and although the enlarged principality of Saxe-Weimar-Eisenach was temporarily split up into the lines Saxe-Weimar, Saxe-Eisenach, and Saxe-Jena, it was again united under Ernest Augustus, who began to reign in 1728. The reign of Charles Augustus, who assumed the government in 1775, is the most brilliant in the history of Saxe-Weimar. An intelligent patron of literature and art, he attracted to his court the leading scholars in Germany; Goethe, Schiller, and Herder were members of this illustrious band, and the little state attracted the eyes of all Europe.

The Congress of Vienna in 1815 added about 660sq.m. to its area and gave its ruler the title of grand-duke. Charles Augustus was the first German sovereign to give a constitution to his state under Article XIII. of the Federal Act. Freedom of the press being secured under its constitution, Weimar became a focus of liberal agitation, which drew down upon the grand-duke the wrath of the reactionary powers (*see* GERMANY, *History*). He was thus forced to curtail some of the liberties granted. In 1866 the grand-duchy joined Prussia against Austria and afterwards entered the North German Confederation and the new German empire. In 1919 the grand-duchy was absorbed in the new republican state of Thuringia, of which Weimar became the capital.

SAXHORN, the generic name of a family of brass wind instruments (not horns but valve-bugles) with cup-shaped mouthpieces, invented by Adolphe Sax and in use chiefly in French and Belgian military bands and in small wind-bands. The saxhorns came into being in 1843, when Sax applied a modification of the valve system, invented in Germany in 1815, to the keyed bugle. The saxhorn consists of a conical tube of a calibre greater than that of French horn and trumpet, but smaller than that of the tubas or bombardons, and capable therefore of producing by overblowing the members of the harmonic series from the 2nd to the 8th, in common with the cornets, bugles, valve-trombones and the Wagner tubas. The saxhorns are furnished with three valves, by means of which the compass is rendered chromatic, and which lower the pitch as in other valve instruments. The difference between saxhorns and bombardons or tubas consists in the calibre of the bore, which in the latter is sufficiently wide in proportion to the length to produce the fundamental note of the harmonic series an octave below the lowest note of the saxhorns.

THE SAXHORN (A MODIFICATION OF THE KEYED BUGLE) INVENTED BY ADOLPHE SAX IN 1843

SAXIFRAGACEAE, in botany, a small family of dicotyledons belonging to the sub-class Archichlamydeae and the cohort Rosales. There are ninety genera with about 750 species distributed through the Arctic and north temperate zone, often alpine. It is represented in Britain by its largest genus *Saxifraga* (*see* SAXIFRAGE), *Chrysosplenium* (golden saxifrage) and *Parnassia* (grass of Parnassus). The plants are herbs, generally with scattered exstipulate leaves with a broad leaf-base. The small flowers are generally arranged in cymose inflorescences and are bisexual, regular and hypogynous, perigynous or more frequently more or less epigynous, this variation in the relative position of the ovary occurring in one and the same genus *Saxifraga*. The free stamens are obdiplostemonous, *i.e.*, those of the outer whorl are opposite to the petals, and two carpels. The carpels are sometimes free, more generally united at the base, or sometimes completely joined to form a one- or two-chambered ovary with two free styles. The fruit is a many-seeded capsule.

Nearly half the species (350) are contained in the genus *Saxifraga*. *Chrysosplenium*, with 45 species, two of which are British, has a very similar distribution. The North American genus *Heuchera* has sometimes apetalous flowers. *Astilbe* has 20 species in temperate Asia and north-eastern North America; *A. japonica* is commonly grown in the spring as a pot-plant, and often misnamed Spiraea.

The family is now extended to include other groups of genera differing in habit and more or less in general conformation from those referred to. Among these is the genus *Ribes*, to which belong the gooseberry (*R. Grossularia*) and currants of gardens. These are shrubs with racemes of flowers which have only one whorl of

stamens (isostemonous), an inferior unilocular ovary with two parietal placentas, and fruit a berry. Other genera are *Hydrangea* (*q.v.*), *Deutzia* and *Philadelphus*, all well-known garden plants; *P. coronarius* is the so-called syringa or mock-orange. They are shrubs or trees with simple generally opposite leaves, pentamerous flowers with epigynous stamens and a tri- to pentalocular ovary. *Escallonia*, which represents a small group of genera with leathery gland-dotted leaves, is also included.

In North America, *Saxifraga* is represented by about 30 species, the other prominent genera being *Ribes* (currant and gooseberry) with 20 species, and *Heuchera* (alum root) with 10 species.

For further details *see* F. Engler and A. Prantl, *Die Natürlichen Pflanzenfamilien* (Leipzig, 1887–1908); A. B. Rendle, *Classification of Flowering Plants* (Cambridge, 1925).

SAXIFRAGE (*Saxifraga*), a genus of plants which gives its name to the family (Saxifragaceae) of which it is a member. There are about 350 species distributed in the temperate and Arctic parts of the northern hemisphere, frequently at considerable heights on the mountains, and also found on the Andes. They are mostly herbs, native to mountains and rocky places, with perennial rootstocks and leaves in tufts or scattered on the flower-stalks. The arrangement of the flowers is very various, as also are the size and colour of the flowers themselves. Thirteen species are natives of Britain, some alpine plants of great beauty (*S. oppositifolia, S. nivalis, S. aizoides*, etc.), and others, like *S. granulata*, frequenting meadows and low ground, while *S. tridactylites* may be found on almost any dry wall. *S. umbrosa* is London pride or St. Patrick's cabbage, a common garden plant, a native of the Spanish peninsula and also of the mountains of west and south-west Ireland. Some 70 species occur in North America, most numerously in the Rocky Mountain region. Well-known species are the early saxifrage (*S. virginiensis*) and the swamp saxifrage (*S. pennsylvanica*), of the eastern United States and Canada, and the tufted saxifrage (*S. caespitosa*), found on rocks in mountains across the continent. Many species are in cultivation, including the numerous alpine species, such as *S. pyramidalis, S. cotyledon*, etc., with tall panicles studded with white flowers, and others, many adapted for rockwork. The strawberry-geranium (*S. sarmentosa*) is an old conservatory and window plant.

SAXO GRAMMATICUS (*c.* 1150–*c.* 1206), Danish historian and poet, belonging to a family of warriors, his father and grandfather having served under Valdemar I., king of Denmark (d. 1182). Saxo was in the service of Archbishop Absalon from about 1182 to 1201. At the archbishop's suggestion he began, about 1185, to write the history of the Danish Christian kings from the time of Sweyn Astridson (d. 1076), but later Absalon prevailed on him to write also the history of the earlier heathen times, and to combine both into a great work, *Gesta Danorum*, or *Historia Danica*. The archbishop died before the work was finished, and therefore the preface, written about 1208, dedicates the work to his successor Archbishop Andreas, and to King Valdemar II. Nothing else is known about Saxo's life and person; a chronicle of 1265 calls him "mirae et urbanae eloquentiae clericus"; and an epitome of his work from about 1340 describes him as "egregius grammaticus, origine Sialandicus."

The surname of "Grammaticus" is probably of later origin, scarcely earlier than 1500, apparently owing to a mistake. The title of "provost of Röskilde," given him in the 16th century, is also probably incorrect, the historian being confounded with an older contemporary, the provost of the same name. Saxo, from his apprenticeship as the archbishop's secretary, had acquired a brilliant but somewhat euphuistic Latin style, and wrote fine Latin verses, but otherwise he does not seem to have had any very great learning or extensive reading. His models of style were Valerius Maximus, Justin and Martianus Capella, especially the last. Occasionally he mentions Bede, Dudo of St. Quentin and Paulus Diaconus, but he does not seem to have studied them or any other historical works thoroughly. His sources are partly Danish traditions and songs, partly the statements of Archbishop Absalon, partly the accounts of Icelanders and, lastly, some few earlier sources, lists of Danish kings and short chronicles, which furnished him with some reliable chronological facts. His work is a loose series of biographies of Danish kings and heroes.

The first nine books of the *Gesta Danorum* comprise traditions of kings and heroes of the half-mythical time up to about 950. Here we have traditions about Fredfrode, about Amleth (Hamlet) and Fenge, about Hrolfr Kraki, Hadding, the giant Starkather, Harald Hildetann and Ragnarr Lodbrok. In this earlier history Saxo has also embodied myths of national gods who in tradition had become Danish kings, for instance, Balder and Hother, and of foreign heroes, likewise incorporated in Danish history, as the Gothic Jarmunrik (A.S. Eormenríc), the Anglian Vermund (A.S. Gármund) and Uffe (A.S. Offa), the German Hedin and Hild and others. Frequently the narrative is interrupted by translations of poems, which Saxo has used as authentic sources, although they are often only a few generations older than himself. In the later books (x.–xvi.) of his work he follows to a greater extent historical accounts, and the more he approaches his own time the fuller and the more trustworthy his relation becomes; especially brilliant is his treatment of the history of King Valdemar and of Absalon. But his patriotism and want of critical sense often blind him to the historical truth.

Saxo's work was published for the first time, from a ms. afterwards lost, in Paris, 1514, by the Danish humanist Christiern Pedersen; this edition was reprinted at Basel, 1534, and at Frankfort, 1576. The last complete edition is that of Alfred Holder (Strassburg, 1886). There is an English translation by O. Elton and F. Y. Powell (London, 1894). There is a later edition of the first nine books of Saxo's works, *Saxo Grammaticus: Die ersten neun Bücher der dänischen Geschichte* (ed. H. Jantzen, 1899–1900); and a commentary and German trans., P. Hermann, *Erläuterungen zu den ersten neun Büchern der dänischen Geschichte des Saxo Grammaticus* (1901–02). There is also a new Danish edition, *Sakses Danesaga* (ed. J. Olick, 1925), and a Danish study of Saxo's life and work, S. C. Larsen, *Saxo Grammaticus, hans Verk og Person* (1925).

SAXONS, a Teutonic people mentioned for the first time by Ptolemy about the middle of the 2nd century. At that time they are said to have inhabited the neck of the Cimbric peninsula, by which we have probably to understand the modern province of Schleswig, together with three islands lying off its western coast. We next hear of them in connection with piratical expeditions in the North sea about the year 286. These raids became more frequent during the 4th century, and at the beginning of the 5th century the northern coast of Gaul and the south-east coast of Britain were known at *litora Saxonica*. During the same period the Saxons appear to have conquered a considerable portion of north-west Germany. According to their own traditions they landed at Hadeln in the neighbourhood of Cuxhaven and seized the surrounding districts from the Thuringians. By the middle of the 4th century they had advanced westwards into the basin of the Ysel, and in the following centuries we find them in possession of the whole of the basin of the Ems, except the coast district, while that of the Weser with all its tributaries belonged to them as far south as the Diemel, where they bordered on the Hessian Franks, the ancient Chatti. The conquest of the Boructuari who dwelt between the Lippe and the Ruhr marks the extent of their progress towards the south-west. This took place shortly before the end of the 7th century. They frequently came into conflict with the Franks and on several occasions had to submit to their supremacy. No thorough conquest was, however, carried until the time of Charlemagne, who, between the years 772 and 785, annexed the whole region as far as the Elbe, destroying in 772 the Irminsul, their great sanctuary, near Marsberg on the Diemel. Up to this time they had remained entirely heathen. At the beginning of the following century Charlemagne also conquered the Saxons known as Nordalbingi in western Holstein, a district which had perhaps been occupied by a southward movement from the original home of the tribe.

It is doubtful how far the Saxons who invaded Britain were really distinct from the Angli, for all their affinities both in language and custom are with the latter and not with the Saxons (Old Saxons) of the Continent. During the 5th century we hear also of Saxon settlements on the coasts of Gaul. The most important were those at the mouth of the Loire founded in the time of Childeric, Clovis's father, and at Bayeux, in a district which remained in their possession until towards the close of the 6th century. From the 6th century onwards, however, we hear practically

nothing of the Saxons as a seafaring people. Almost all the southern coast of the North sea had now come into the possession of the Frisians, and one can hardly help concluding that most of the maritime Saxons had either voluntarily or by conquest become incorporated in that kingdom.

See Ptolemy ii. 11; Eutropius ix. 21; Zosimus iii. 6; Ammianus Marcellinus xxvi. 4. 5, xxvii. 8. 5, xxviii. 2. 12, 7. 8, xxx. 5. 1 and 4; *Notitia dignitatum;* Gregory of Tours, *Historia Francorum,* ii. 19, iv. 10. 14, v. 27, x. 9; Bede, *Hist. Eccl.* v. 10 *seq.; Annales Einhardi; Translatio S. Alexandri;* Hucbald, *Vita S. Lebuini;* Widukind, *Res Gestae Saxonicae,* i. 1 ff. (F. G. M. B.)

SAXONY, a republic of Germany, ranking among the constituent states of the German Reich fifth in area and third in population, bounded on the south by Czechoslovakia, on the west by Bavaria and Thuringia and on the west, north and east by Prussia. Its frontiers have a circuit of 760 m. and, with the exception of some small exclaves and enclaves, it forms a compact whole of a triangular shape, its base extending from north-east to south-west, and its apex pointing north-west. Its greatest length is 130 m.; greatest breadth 93 m., and total area 5,787 sq.m.

Physical Features.—Saxony belongs almost entirely to the central mountain region of Germany, only the districts along the north border and around Leipzig descending into the great north-European plain. The chief mountain range is the Erzgebirge, stretching for 90 m. along the south border, and reaching in the Fichtelberg (3,979 ft. and 3,953 ft.) the highest elevation in the country. The west and south-west is occupied by ramifications and subsidiary groups of this range, such as the Central Saxon chain, and the Oschatz group. The south-east angle of Saxony is occupied by the mountains of Upper Lusatia (highest summit 2,600 ft.). North-west from this group, and along both banks of the Elbe, which divides it from the Erzgebirge, extends the picturesque Saxon Switzerland. The action of water and ice upon the soft sandstone of which the hills here are chiefly composed has produced deep gorges and isolated fantastic peaks, but the highest summit attains a height of only 1,830 ft.; the more interesting peaks, as the Lilienstein, Königstein and the Bastei, are lower. Saxony lies almost wholly in the basin of the Elbe, which has a navigable course of 72 m. from south-east to north-west. The Mulde, formed of two branches, is the second river of Saxony; others are the Black Elster, the White Elster, the Pleisse and the Spree, all part of the Elbe system. There are no lakes of any size. The best known of many mineral springs is at Bad Elster in the Vogtland.

Climate.—The climate is mildest in the valleys of the Elbe, Mulde and Pleisse and severest in the Erzgebirge. The average temperature varies from 48° to 50°. The Erzgebirge is the rainiest district, 27½ to 33½ in. falling yearly; the amount decreases as one proceeds northward, and Leipzig, with an average annual rainfall of 17 in., enjoys the driest climate.

Population.—In 1925 the population of Saxony was 4,970,301, or 858·8 per square mile. Except the free towns, Saxony is the most densely peopled member of the German Republic. The growth of the population since 1815, when Saxony received its present limits, has been as follows: (1815) 1,178,802; (1830) 1,402,066; (1840) 1,706,275; (1864) 2,344,094; (1875) 2,760,586; (1895) 3,787,688; (1905) 4,508,601. The preponderating industrial activity fosters the tendency of the population to concentrate in towns, and no German state, with the exception of the Hanseatic towns, has so large a proportion of urban population. The people of Saxony are chiefly of pure Teutonic stock; a proportion are Germanized Slavs, and to the south of Bautzen there is a large settlement of Wends, who retain their language.

The chief towns are Dresden (pop. 1925, 608,025), Leipzig (660,140), Chemnitz (323,153), Plauen (109,953), Zwickau (71,826), Zittau (40,387), Meissen (41,800), Freiberg (34,146), Bautzen (44,000), Meerane (23,421), Glauchau (25,502), Reichenbach (30,394), Krimmitzschau (27,253), Werdau (21,140), Pirna (30,237).

Communications.—The roads in Saxony are numerous and good, and there are over 2,119 m. of railway. The only navigable river is the Elbe.

Agriculture.—Saxony is one of the most fertile parts of Germany, and is highly developed agriculturally. Fertility diminishes as we ascend towards the south, until on the bleak crest of the Erzgebirge cultivation ceases. In 1834 a law was passed providing for the union of the scattered lands belonging to each proprietor, and that may be considered the dawn of modern Saxon agriculture. The richest grain districts are near Meissen, Grimma, Bautzen, Döbeln and Pirna. The chief crop is rye, but oats are hardly second to it. Wheat and barley are grown in considerably less quantity. Very large quantities of potatoes are grown, especially in the Vogtland. Beet is also grown extensively. Flax is grown in the Erzgebirge and Lusatian mountains, where the manufacture of linen was at one time a flourishing domestic industry. Enormous quantities of cherries, plums and apples are annually borne by the trees round Leipzig, Dresden and Colditz. The Saxon vineyards, chiefly on the banks of the Elbe near Meissen and Dresden, have passed through difficult times of late years, owing to the ravages of the phylloxera.

Live Stock.—Cattle rearing, which has been an industry since the advent of the Wends in the 6th century, is important on the extensive pastures of the Erzgebirge and in the Vogtland. In 1765 the regent Prince Xaver imported 300 merino sheep from Spain, and so improved the native breed by this new strain that Saxon sheep were eagerly imported by foreign nations to improve their flocks, and "Saxon electoral wool" became one of the best brands in the market. Sheep farming, however, has considerably declined within the last few decades. Swine furnish a very large proportion of the flesh diet of the people. Geese abound particularly round Leipzig and in Upper Lusatia, poultry about Bautzen.

Forests.—The forests of Saxony are extensive and have long been well cared for both by government and by private proprietors. The famous school of forestry at Tharandt was founded in 1811. The Vogtland is the most densely wooded portion of Saxony, and next comes the Erzgebirge.

Mining.—Silver was raised in the 12th century, and argentiferous lead is still the most valuable ore mined; tin, iron and cobalt rank next, and coal is one of the chief exports. Copper, zinc and bismuth are also worked. The country is divided into four mining districts: Freiberg, where silver and lead are the chief products; Altenberg, where tin is mainly raised; Schneeberg, yielding cobalt, nickel and ironstone; and Johanngeorgenstadt, with ironstone and silver mines. The coal is found principally in two fields—one near Zwickau, and the other in the governmental district of Dresden. Brown coal or lignite is found chiefly in the north and north-west. Peat is especially abundant on the Erzgebirge. Immense quantities of bricks are made all over the country. Excellent sandstone for building is found on the hills of the Elbe. Fine porcelain clay occurs near Meissen, and coarser varieties elsewhere.

Industries.—The central-European position of Saxony has fostered its commerce; and its manufactures have been encouraged by the abundant water-power throughout the country. Nearly one-half of the motive power used in Saxon factories is supplied by the streams, of which the Mulde, in this respect, is the chief. The early foundation of the Leipzig fairs, and the enlightened policy of the rulers of the country, have also done much to develop its commercial and industrial resources. The manufacture of textiles is carried on at Zwickau, Chemnitz, Glauchau, Meerane, Hohenstein, Kamenz, Pulsnitz and Bischofswerda. The centre of the cotton manufacture (especially of cotton hosiery) is Chemnitz; cotton-muslins are made throughout the Vogtland, ribbons at Pulsnitz and its neighbourhood. Woollen cloth and buckskin are woven at Kamenz, Bischofswerda and Grossenhain, all in the north-east, woollen and half-woollen underclothing at Chemnitz, Glauchau, Meerane and Reichenbach; while Bautzen and Limbach produce woollen stockings. Linen is manufactured chiefly in the mountains of Lusatia, where the looms are still to some extent found in the homes of the weavers. Damask is produced at Gross-Schönau and other places. Lace-making, discovered or introduced by Barbara Uttmann in the latter half of the 16th century, and now fostered by government schools, was long an important domestic industry among the villages of the Erzgebirge, and has attained to a great industry

in Plauen. Straw-plaiting is carried on by the inhabitants of the mountain slopes between Gottleuba and Lockwitz. Waxcloth is manufactured at Leipzig, and artificial flowers at Leipzig and Dresden. Stoneware and earthenware are made at Chemnitz, Zwickau, Bautzen and Meissen, porcelain ("Dresden china") at Meissen, chemicals in and near Leipzig. Döbeln, Werdau and Lossnitz are the chief seats of the Saxon leather trade; cigars are very extensively made in the town and district of Leipzig, and hats and pianofortes at Leipzig, Dresden and Chemnitz. Paper is made chiefly in the west of Saxony. Machinery of all kinds is produced, from the sewing-machines of Dresden to the steam-locomotives and marine-engines of Chemnitz. The last-named place, though the centre of the iron-manufacture of Saxony, has to import every pound of iron by railway. The leading branch is the machinery used in the industries of the country—mining, paper-making and weaving. The very large printing trade of Leipzig encourages the manufacture of printing-presses in that city. In 1925–26 Saxony contained 144 active breweries. The smelting and refining of the metal ores is also an important industry.

The principal exports are wool, woollen, cotton, linen goods, machinery, china, pianofortes, cigarettes, flannels, stockings, curtains and lace, cloth from Reichenbach and Zittau, watches of superlative value from Glashütte and toys from the Vogtland.

Constitution.—The Constitution of the Republic of Saxony dates from Nov. 1, 1920. The Landtag consists of 96 members.

For administrative purposes Saxony is divided into five Kreishauptmannschaften, or governmental departments, centring in the cities of Dresden, Leipzig, Chemnitz, Bautzen and Zwickau respectively. The Oberlandesgericht has its seat at Dresden, and the Reichsgericht—the supreme court of law for the whole German Reich—at Leipzig.

Church.—The great majority of the inhabitants of Saxony are Protestants. The government of the Evangelical-Lutheran Church is vested in the Evangelical Consistory at Dresden. Its representative assembly consisting of 40 clergymen and 46 lay members (1923) is called a synod (*Synode*). The Moravian Brethren have their chief seat at Herrnhut.

Education.—Of the four universities founded by the Saxon electors at Leipzig, Jena, Wittenberg, later transferred to Halle, and Erfurt, now extinct, only the first is included in the present Republic of Saxony. There are famous endowed schools (Fürstenschulen) at Meissen and Grimma. Saxony is particularly well-equipped with technical schools, the textile industries being especially fostered by numerous schools of weaving, embroidery and lace-making; but the mining academy at Freiberg and the school of forestry at Tharandt are probably the most widely known. The conservatory of music at Leipzig and the art collections at Dresden have a world-wide reputation.

HISTORY

The name Saxony has been borne by two distinct blocks of territory. The first was the district in the north-west of Germany, inhabited originally by the Saxons, which became a duchy and attained its greatest size and prosperity under Henry the Lion in the 12th century. In 1180 it was broken up, and the name of Saxony disappeared from the greater part of it, remaining only with the districts around Lauenburg and Wittenberg. Five centuries later Lauenburg was incorporated with Hanover, and Wittenberg is the nucleus of modern Saxony, the name being thus transferred from the west to the east of Germany. In 1423 Meissen and Thuringia were united with Saxe-Wittenberg under Frederick of Meissen, and gradually the name of Saxony spread over all the lands ruled by this prince and his descendants.

The earlier Saxony was the district lying between the Elbe and the Saale on the east, the Eider on the north and the Rhine on the west, with a fluctuating boundary on the south. This territory was a stronghold of Germanic heathenism and included at Eresburg, the modern Marsberg, one of the chief Germanic sanctuaries, marked by the *Irminsul,* a wooden pillar which was the centre of Saxon worship. The prolonged resistance which the Saxons offered to Christianity was chiefly due to their hostility to the Franks who threatened their independence. The reduction of the Saxons was attempted by Charles Martel and Pippin the short, and was finally carried through in a series of campaigns by Charlemagne (*q.v.*). Before his death Saxony had permanently passed under Frankish supremacy, and within a century it had come to form an outpost of German and Christian influence against the Slavs of the provinces south of the Baltic.

The conversion of the Saxons to Christianity, which during this time had been steadily progressing, was continued in the reign of the emperor Louis I. Bishoprics were established at Bremen, Münster, Verden, Minden, Paderborn, Osnabrück, Hildesheim, Hamburg and Halberstadt. The abbey of Corvey soon became a centre of learning for the country, and the Saxons undertook with the eagerness of converts the conversion of their heathen neighbours. Towards the middle of the century there are signs of a reaction against Frankish rule and towards heathenism among the Saxon free peasantry, but it had no permanent result, and the connection with the empire was unbroken. By the treaty of Verdun in 843 Saxony fell to Louis the German, but he paid little attention to the northern part of his kingdom, which was harassed by the Normans and the Slavs. About 850, however, he appointed a Saxon noble named Liudolf as margrave to defend the *Limes Saxoniae,* a narrow strip of land on the eastern frontier. Liudolf, who is sometimes called "duke of the East Saxons," carried on a vigorous warfare against the Slavs and extended his influence over other parts of Saxony. He died in 866, and was succeeded by his son Bruno, who was killed fighting the Normans in 880. Liudolf's second son, Otto the Illustrious, was recognized as duke of Saxony by King Conrad I., and on the death of Burkhard, margrave of Thuringia in 908, obtained authority over that country also. He made himself practically independent in Saxony, and played an important part in the affairs of the empire. He died in 912 and his son Henry I., the Fowler, not only retained his hold over Saxony and Thuringia, but in 919 was elected German king. He extended the Saxon frontier almost to the Oder, improved the Saxon forces by training and equipment, established new marks, and erected forts on the frontiers for which he provided regular garrisons. Towns were walled, where it was decreed markets and assemblies should be held, churches and monasteries were founded, civilization was extended and learning encouraged. Henry's son, Otto the Great, was crowned emperor in 962, and his descendants held this dignity until the death of the emperor Otto III. in 1002. Under this able dynasty the Slavs were driven back, the domestic policy of Henry the Fowler was continued, the Saxon court became a centre of learning visited by Italian scholars, and in 968 an archbishopric was founded at Magdeburg for the lands east of the Elbe. The extent of Otto the Great's dominions compelled him to delegate much of his authority in Saxony and in 960 he gave to a trusted relative Hermann Billung certain duties and privileges on the eastern frontier, and from time to time appointed him as his representative in Saxony. Hermann gradually extended his authority, and when he died in 973 was followed by his son Bernard I., who was undoubtedly duke of Saxony in 986. When Henry II. was chosen German king in 1002 he met the Saxons at Merseburg, and on promising to observe their laws Bernard gave him the sacred lance, thus entrusting Saxony to his care. Bernard was succeeded by his son Bernard II., who took up a hostile attitude towards the German kings, Conrad II. and Henry III. His son and successor Ordulf, who became duke in 1059, carried on a long and obstinate struggle with Adalbert, archbishop of Bremen, who was compelled to cede one-third of his possessions to Ordulf's son Magnus in 1066. The emperor Henry III. sought to win the allegiance of the Saxons by residing among them. He built a castle at Goslar and the Harzburg; and his successor Henry IV. also spent much time in Saxony.

In 1070 Otto of Nordheim, duke of Bavaria, who held large estates in this country, was accused of a plot to murder Henry, and his lands were confiscated. Otto, in alliance with Magnus, won considerable support in Saxony, but after some fighting both submitted and were imprisoned; and Magnus was still in confinement when on his father's death in 1072 he became titular duke of Saxony. As he refused to give up his duchy he was kept

in prison, while Henry confiscated the estates of powerful nobles, demanded the restoration of ducal lands by the bishops, and garrisoned newly-erected forts with Swabians. These proceedings aroused suspicion and discontent, which were increased when the emperor assembled an army, ostensibly to attack the Slavs. The Saxon nobles refused to join the host until their grievances were redressed, and in 1073 a league was formed at Wormesleben. When the insurgents under Duke Otto were joined by the Thuringians, Henry was compelled in 1074 to make various concessions to them, and in particular to release Magnus. At last Henry, having obtained help from the princes of the Rhineland, attacked and defeated the Saxons at Hohenburg near Langensalza but pardoned Otto, whom he appointed administrator of the country. The Saxons, however, were not quite subdued; risings took place from time to time, and the opponents of Henry IV. found considerable support in Saxony. During the century which followed the death of Hermann Billung, there had been constant warfare with the Slavs, but although the emperors had often taken the field, the Saxons had been driven back to the Elbe, which was at this time their eastern boundary. In 1106 Magnus died, and the German king Henry V. bestowed the duchy upon Lothair, count of Supplinburg, whose wife Richenza inherited the Saxon estates of her grandfather Otto of Nordheim, on the death of her brother Otto in 1116. Lothair quickly made himself independent, defeated Henry at Welfesholz in 1115, and prosecuted the war against the Slavs with vigour. In 1125 he became German king, and in 1137 gave Saxony to Henry the Proud, duke of Bavaria, who had married his daughter Gertrude, and whose mother Wulfhild was a daughter of Magnus Billung. The succeeding German king Conrad III. refused to allow Henry to hold two duchies, and gave Saxony to Albert the Bear, margrave of Brandenburg, who like his rival was a grandson of Magnus Billung. Albert's attempts to obtain possession failed, and after Henry's death in 1139 he formally renounced Saxony in favour of Henry's son, Henry the Lion (*q.v.*). The new duke improved its internal condition, increased its political importance, and pushed its eastern frontier towards the Oder. In 1180, however, he was placed under the imperial ban and Saxony was broken up. Henry retained Brunswick and Luneburg; Westphalia, as the western portion of the duchy was called, was given to Philip, archbishop of Cologne, and a large part of the land was divided among nine bishops and a number of counts who thus became immediate vassals of the emperor. The title duke of Saxony was given to Bernard, the sixth son of Albert the Bear, together with the small territories of Lauenburg and Wittenberg, which were thus the only portions of the former duchy which now bore the name of Saxony. Bernard, whose paternal grandmother, Eilicke, was a daughter of Magnus Billung, took a prominent part in German affairs, but lost Lauenburg which was seized by Waldemar II., king of Denmark. Dying in 1212, Bernard was succeeded in Wittenberg by his younger son Albert I., who recovered Lauenburg after the defeat of Waldemar at Bornhöved in 1227. Albert died in 1260, and soon after his death his two sons divided his territories, when the elder son John took Lauenburg which was sometimes called lower Saxony, and the younger, Albert II., took Wittenberg or upper Saxony. Both retained the ducal title and claimed the electoral privilege, a claim which the Lauenburg line refused to abandon when it was awarded to the Wittenberg line by the Golden Bull of 1356.

Saxe-Lauenburg was governed by John until his death in 1285, when it passed to his three sons John II., Albert III. and Eric I. As Albert had no sons the duchy was soon divided into two parts, until on the death of duke Eric III., a grandson of John II., in 1401, it was reunited by Eric IV., a grandson of Eric I. When Eric IV. died in 1412 he was succeeded by his son Eric V., who made strenuous but vain efforts to obtain the electoral duchy of Saxe-Wittenberg, which fell vacant on the death of the elector Albert III. in 1422. Eric died in 1436 and was followed by his brother Bernard IV., whose claim to exercise the electoral vote was quashed by the electors in 1438; and who was succeeded by his son John IV. in 1463. The next duke, John's son Magnus I., spent much time in struggles with the archbishop of Bremen and the bishop of Ratzeburg; he also assisted the progress of the Reformation in Lauenburg. Magnus, who was formally invested with the duchy by the emperor Charles V. in 1530, was the first duke to abandon the claim to the electoral privilege. After his death in 1543 his son Francis I. reigned for the succeeding 28 years, and his grandsons, Magnus II. and Francis II., until 1619. Francis, who did something to improve the administration of his duchy, was succeeded in turn by his two sons and his two grandsons; but on the death of Julius Francis, the younger of his grandsons, in 1689 the family became extinct.

Several claimants to Saxe-Lauenburg thereupon appeared, the most prominent of whom were George William, duke of Lüneburg-Celle, and John George III., elector of Saxony. George William based his claim upon a treaty of mutual succession made in 1369 between his ancestor Magnus II., duke of Brunswick, and the reigning dukes of Saxe-Lauenburg. John George had a double claim. Duke Magnus I. had promised that in case of the extinction of his family Lauenburg should pass to the family of Wettin, an arrangement which had been confirmed by the emperor Maximilian I. in 1507. Secondly, John George himself had concluded a similar treaty with Julius Francis in 1671. In 1689 the elector received the homage of the people of Lauenburg. George William, however, took Ratzeburg, and held it against the troops of a third claimant, Christian V., king of Denmark; and in 1702 he bought off the claim of John George, his successor being invested with the duchy in 1728. Since that date its history has been identified with that of Hanover (*q.v.*).

In Saxe-Wittenberg Albert II. was succeeded in 1298 by his son Rudolph I., who was followed in 1356 by his son Rudolph II. He in turn was succeeded in 1370 by his half-brother Wenceslaus, who temporarily acquired the duchy of Lüneburg for his house. He was followed in 1388 by his eldest son Rudolph III. Lavish expenditure during the progress of the council of Constance reduced Rudolph to poverty and on the death in 1422 of his brother Albert III., who succeeded him in 1419, this branch of the family became extinct.

THE ELECTORATE

A new era in the history of Saxony dates from 1423, when the Emperor Sigismund bestowed the vacant electoral duchy of Saxe-Wittenberg upon Frederick, margrave of Meissen. Frederick was a member of the family of Wettin, which since his day has played a prominent part in the history of Europe, and he owed his new dignity to the money and other assistance which he had given to the emperor during the Hussite war. The new and more honourable title of elector of Saxony now superseded his other titles, and the name Saxony gradually spread over his other possessions, which included Meissen and Thuringia as well as Saxe-Wittenberg. His new position as elector combined with his personal qualities to make him one of the most powerful princes in Germany, and had the principle of primogeniture been established in his country, Saxony and not Prussia might later have been the leading power in the German empire. He died in 1428, just before his lands were ravaged by the Hussites in 1429 and 1430. The division of his territory between his two sons, the elector Frederick II. and William, occasioned a destructive internecine war. Frederick II.'s two sons, Ernest and Albert, succeeded to their father's possessions in 1464, and for 20 years ruled together peaceably. The land prospered rapidly during this respite from the horrors of war. The childless death of their uncle William in 1482 brought Thuringia to the two princes, and Albert insisted on a division of their common possessions. The important partition of Leipzig accordingly took place in 1485, and resulted in the foundation of the two main lines of the Saxon house. The lands were never again united. Ernest, the elder brother, obtained Saxe-Wittenberg with the electoral dignity, Thuringia and the Saxon Vogtland; while Albert received Meissen, Osterland being divided between them. Something was still held in common, and the division was probably made intricate to render war difficult.

The Reformation Period.—The elector Ernest was succeeded in 1486 by his son, Frederick the Wise, one of the most

illustrious princes in German history. Under him Saxony was perhaps the most influential state in the empire, and became the cradle of the Reformation. He died in 1525 while the Peasants' War was desolating his land, and was succeeded by his brother John, who was an enthusiastic supporter of the reformed faith and who shared with Philip, landgrave of Hesse, the leadership of the league of Schmalkalden. John's son and successor, John Frederick the Magnanimous, who became elector in 1532, might with equal propriety have been surnamed the Unfortunate. He took part in the war of the league of Schmalkalden, but in 1547 he was captured at Mühlberg by the Emperor Charles V. and was forced to sign the capitulation of Wittenberg. This deed transferred the electoral title and a large part of the electoral lands from the Ernestine to the Albertine branch of the house, whose astute representative, Maurice, had taken the imperial side during the war. Only a few scattered territories were reserved for John Frederick's sons, although these were increased by the treaty of Naumburg in 1554, and on them were founded the Ernestine duchies of Saxe-Gotha, Saxe-Weimar, Saxe-Coburg, Saxe-Meiningen and Saxe-Altenburg. For the second time in the history of the Saxon electorate the younger line secured the higher dignity, for the Wittenberg line was junior to the Lauenburg line. The Albertine line became later the royal line of Saxony.

Maurice, who became elector of Saxony in consequence of the capitulation of Wittenberg, was a Protestant, but he did not allow his religious faith to blind him to his political interests. He refused to join the other Protestant princes in the league of Schmalkalden, but made a secret treaty with Charles V. His fidelity to Charles V. was rewarded by the capitulation of Wittenberg. All the lands torn from John Frederick were not, however, assigned to Maurice; he was forced to acknowledge the superiority of Bohemia over the Vogtland and the Silesian duchy of Sagan. Moreover, Roman Catholic prelates were reinstated in the bishoprics of Meissen, Merseburg and Naumburg-Zeitz. Recognizing now as a Protestant prince that the best alliance for securing his new possessions was not with the emperor, but with the other Protestant princes, Maurice began to withdraw from the former and to conciliate the latter. In 1552, suddenly marching against Charles at Innsbruck, he drove him to flight and then extorted from him the peace of Passau.

Amid the distractions of outward affairs, Maurice had not neglected the internal interests of Saxony. To its educational advantages, already conspicuous, he added the three *Fürstenschulen* at Pforta, Grimma and Meissen, and for administrative purposes, especially for the collection of taxes, he divided the country into the four circles of the Electorate, Thuringia, Meissen and Leipzig. During his reign coal-mining began in Saxony. Over 200 religious houses were suppressed, the funds being partly applied to educational purposes. The country had four universities, those of Leipzig, Wittenberg, Jena and Erfurt; books began to increase rapidly, and, by virtue of Luther's translation of the Bible, the Saxon dialect became the ruling dialect of Germany.

Augustus I., brother and successor of Maurice, was one of the best domestic rulers that Saxony ever had. He increased the area of the country by the "circles" of Neustädt and the Vogtland, and by parts of Henneberg and the silver-yielding Mansfeld, and he devoted his long reign to the development of its resources. Under him lace-making began on the Erzgebirge, and cloth-making flourished at Zwickau. With all his virtues, however, Augustus was an intolerant Lutheran, and used very severe means to exterminate the Calvinists. Under John George (succeeded 1611) the country was devastated by the Thirty Years' War. After the death of Gustavus Adolphus at the battle of Lützen, not far from Leipzig, in 1632, the elector, who was at heart an imperialist, detached himself from Sweden with whom he had been allied since 1629, and in 1635 concluded the peace of Prague with the emperor. By this peace he was confirmed in the possession of Upper and Lower Lusatia. Saxony had now to suffer from the Swedes a repetition of the devastations of Wallenstein. No other country in Germany was so scourged by this terrible war. When the war was ended by the peace of Westphalia in 1648, Saxony found that its influence had begun to decline in Germany. John George's will made the decline worse by detaching the three duchies of Saxe-Weissenfels, Saxe-Merseburg and Saxe-Zeitz as appanages for his younger sons. By 1746, however, these lines were all extinct, and their possessions had returned to the main line.

The 18th Century.—The next three electors, who each bore the name of John George, had uneventful reigns. John George IV. was succeeded in 1694 by his brother Frederick Augustus I., or Augustus the Strong. This prince was elected king of Poland as Augustus II. in 1697, but any weight which the royal title might have given him in the empire was more than counterbalanced by the fact that he became a Roman Catholic in order to qualify for the new dignity. In order to defray the expenses of Poland's wars with Charles XII. Augustus pawned and sold large districts of Saxon territory, while he drained the electorate of both men and money.

From this reign dates the privy council (*Geheimes Kabinet*), which lasted till 1830. The caste privileges of the estates (*Stände*) were increased by Augustus, a fact which tended to alienate them more from the people, and so to decrease their power. Frederick Augustus II., who succeeded his father in the electorate in 1733, and was afterwards elected to the throne of Poland as Augustus III., was an indolent prince, wholly under the influence of Count Heinrich von Brühl (*q.v.*). Under him Saxony sided with Prussia in the First Silesian War, and with Austria in the other two. It gained nothing in the first, lost much in the second, and in the third, the Seven Years' War (1756–63), suffered renewed miseries. The country was deserted by its king and his minister, who retired to Poland. By the end of the war it had lost 90,000 men and 100,000,000 thalers; its coinage was debased and its trade ruined; and the whole country was in a state of frantic disorder. The elector died seven months after his return from Poland; Brühl died 23 days later. The connection with Poland was now at an end. The elector's son and successor, Frederick Christian, survived his father only two months, dying also in 1763, leaving a son, Frederick Augustus III., a boy of 13. Prince Xaver, the elector's uncle, was appointed guardian, and he set himself to the work of healing the wounds of the country.

THE KINGDOM OF SAXONY

Frederick assumed the government in 1768, and in his long and eventful reign, which saw the electorate elevated to the dignity of a kingdom, though deprived of more than half its area, he won the surname of the Just. As he was the first king of Saxony, he is usually styled Frederick Augustus I. When the Bavarian succession fell open in 1777, Frederick Augustus joined Prussia in protesting against the absorption of Bavaria by Austria, and Saxon troops took part in the bloodless "potato-war." The elector commuted his claims in right of his mother, the Bavarian princess Maria Antonia, for 6,000,000 florins, which he spent chiefly in redeeming Saxon territory that had been pawned to other German states. When Saxony joined the *Fürstenbund* in 1785, it had an area of 15,185 sq.m. and a population of nearly 2,000,000, but its various parts had not yet been combined into a homogeneous whole, for the two Lusatias, Querfurt, Henneberg and the ecclesiastical foundations of Naumburg and Merseburg had each a separate diet and government, independent of the diet of the electorate proper. In 1791 Frederick declined the proffered crown of Poland. Next year saw the beginning of the great struggle between France and Germany. Frederick's first policy was one of abstention but when war broke out in 1806 against Napoleon, 22,000 Saxon troops shared the defeat of the Prussians at Jena, but the elector immediately afterwards abandoned his former ally. At the peace of Posen (Dec. 11, 1806) Frederick assumed the title of king of Saxony, and entered the Confederation of the Rhine as an independent sovereign, promising a contingent of 20,000 men to Napoleon.

In 1807 his submission was rewarded with the duchy of Warsaw (to which Cracow and part of Galicia were added in 1809) and the district of Kottbus, though he had to surrender some of his former

territory to the new kingdom of Westphalia. The king of Saxony's faith in Napoleon was shaken by the disasters of the Russian campaign, but when the allies invaded Saxony in the spring of 1813, he refused to declare against Napoleon and fled to Prague, though he withdrew his contingent from the French army. After Napoleon's victory at Lützen (May 2, 1813), the Saxon king and the Saxon army were once more at the disposal of the French. During the battle of Leipzig in Oct. 1813, the popular Saxon feeling was displayed by the desertion of the Saxon troops to the side of the allies. Frederick was taken prisoner in Leipzig, and the government of his kingdom was assumed for a year by the Russians. The congress of Vienna assigned the northern portion, consisting of 7,800 sq.m., with 864,404 inhabitants, to Prussia, leaving 5,790 sq.m., with a population of 1,182,744, to Frederick, who was permitted to retain his royal title. On June 8, 1815, King Frederick joined the new German Confederation.

Constitutionalism.—From the partition in 1815 to the war of 1866 the history of Saxony is mainly a narrative of the slow growth of constitutionalism and popular liberty within its limits. Its influence on the general history of Europe ceased when the old empire was dissolved. In the new German empire it was too completely overshadowed by Prussia to have any objective importance by itself. Frederick lived 12 years after the division of his kingdom. The commercial and industrial interests of the country continued to be fostered, but only a few of the most unavoidable political reforms were granted. Religious equality was extended to the Reformed Church in 1818, and the separate diet of Upper Lusatia was abolished. Frederick Augustus was succeeded in 1827 by his brother Anthony who initiated a few unimportant reforms. An active opposition began to make itself evident in the diet and in the press, and in 1830, under the influence of the July revolution in Paris, riots broke out in Leipzig and Dresden, and a constitution was promised. After consultation with the diet the king promulgated, on Sept. 4, 1831, a new constitution by which the feudal estates were replaced by two chambers, largely elective, and the privy council by a responsible ministry of six departments.

While Saxony's political liberty was thus enlarged, its commerce and credit were stimulated by its adhesion to the Prussian *Zollverein* and by the construction of railways. Anthony had died in 1836, and Frederick Augustus II., since 1830 co-regent, became sole king. The burning questions were the publicity of legal proceedings and the freedom of the press; and on these the government sustained its first heavy defeat in the lower chamber in 1842. In 1843 the prime minister Lindenau was forced by the action of the aristocratic party to resign, and was replaced by Julius Traugott von Könneritz (1792–1866), a statesman of reactionary views. This increased the opposition of the Liberal middle classes to the Government. Religious considerations arising out of the attitude of the Government towards the "German Catholics," and a new constitution for the Protestant Church, began to mingle with purely political questions.

Warned by the sympathy excited in Saxony by the revolutionary events at Paris in 1848, the king dismissed his reactionary ministry, and a Liberal cabinet took its place in March 1848. The privileges of the nobles were curtailed; the administration of justice was put on a better footing; the press was unshackled; publicity in legal proceedings was granted; trial by jury was introduced for some special cases; and the German Catholics were recognized. The feudal character of the first chamber was abolished, and its members made mainly elective from among the highest tax-payers, while an almost universal suffrage was introduced for the second chamber. The first demand of the overwhelmingly democratic diet returned under this reform bill was that the king should accept the German constitution elaborated by the Frankfort parliament. Frederick, alleging the danger of acting without the concurrence of Prussia, refused, and dissolved the diet. The public demonstration at Dresden in favour of the Frankfort constitution was prohibited on May 2, 1849. The people seized the town and barricaded the streets; Dresden was almost destitute of troops; and the king fled to the Königstein. The rebels then appointed a provisional Government, consisting of Tzschirner, Heubner and Todt, though the true leader of the insurrection was the Russian Bakunin. Meanwhile Prussian troops had arrived to aid the Government, and after two days' fierce street fighting the rising was quelled. The bond with Prussia now became closer, and Frederick entered with Prussia and Hanover into the temporary "alliance of the three kings"; but in 1850 he accepted the invitation of Austria to send deputies to the restored federal diet at Frankfort. The first chamber immediately protested against this step, and refused to consider the question of a pressing loan. The king retorted by dissolving the diet and summoning the old estates abolished in 1848. Beust became minister for both home and foreign affairs in 1852, and under his guidance the policy of Saxony became more and more hostile to Prussia and friendly to Austria.

The sudden death of the king in 1854 left the throne to his brother John whose name is known in German literature as a translator and annotator of Dante. His brother's ministers remained but their views gradually became somewhat liberalized with the spirit of the times. Beust, however, still retained his federalistic and philo-Austrian views. When war was declared between Prussia and Austria in 1866, Saxony took the side of Austria. On the conclusion of peace Saxony lost no territory, but had to pay a war indemnity of 10,000,000 thalers, and was compelled to enter the North German Confederation.

Franchise.—During the peace negotiations Beust had resigned and entered the Austrian service, and on Nov. 15 the king in his speech from the throne announced his intention of being faithful to the new Confederation as he had been to the old. On Feb. 7, 1867, a military convention was signed with Prussia which placed the army under the king of Prussia. The postal and telegraph systems were also placed under the control of Prussia, and the representation of the Saxon crown at foreign courts was merged in that of the Confederation. A new electoral law reformed the Saxon diet by abolishing the old distinction between the various "estates" and lowering the qualification for the franchise; the result was a Liberal majority in the lower house and a period of civil and ecclesiastical reform. John was succeeded in 1873 by his elder son Albert (1832–1902) who had added to his military reputation during the war of 1870. Under this prince the course of politics in Saxony presented little of general interest, except perhaps the spread of the doctrines of Social Democracy, which was especially remarkable in Saxony. The number of Social Democratic delegates in a diet of 80 members rose from 5 in 1885 to 14 in 1895. So alarming did the growth appear, that the other parties combined, and on March 28, 1896, a new electoral law was passed, introducing indirect election and a franchise based on a triple division of classes determined by the amount paid in direct taxation. This resulted in 1901 in the complete elimination of the Socialists from the diet. On June 7, 1902, King Albert died, and was succeeded by his brother as King George. An extraordinary situation had been created by the electoral law of 1896. This law had in effect secured the misrepresentation of the mass of the people in the diet, the representation of the country population at the expense of that of the towns, of the interests of agriculture as opposed to those of industry. The result was displayed in the elections of 1903 to the German imperial parliament, when, under the system of universal suffrage, of 23 members returned 22 were Social Democrats. This led to proposals for a slight modification in the franchise for the Saxon diet (1904), which were not accepted. In the elections of 1906, however, only 8 of the Social Democrats succeeded in retaining their seats. In 1907 the Government announced their intention of modifying the electoral system in Saxony by the adding of representation for certain professions to that of the three classes of the electorate. This was, however, far from satisfying the parties of the extreme Left, and the strength of Social Democracy in Saxony was even more strikingly displayed in 1909 when, in spite of plural voting, under a complicated franchise, 25 Socialist members were returned to the Saxon diet.

King George died on Oct. 15, 1904, and was succeeded by his son as King Frederick Augustus III., under whom the conflict about the constitution continued. The Left demanded a reform of the first chamber, the upper house, which should break the

predominance of the agrarians in that house and allow to commerce, industry and handicrafts a greater influence. This was reinforced in 1917 by the agitation of the extreme Left in the diet for the early conclusion of peace.

The Revolution.—On Oct. 26, 1918 the cabinet gave place to a more liberal Government under Dr. Heinze. On Nov. 9, 1918, the revolution broke out, on Nov. 10 the republic was proclaimed, and King Frederick Augustus abdicated on Nov. 13. A cabinet of commissaries of the people (*Volksbeauftragte*), composed exclusively of Independent Socialists, first held power, but was succeeded by a Government of Majority Socialists. A new republican constitution was adopted on Nov. 1, 1920. The revolutionary agitation remained active in Saxony throughout 1919, 1920 and 1921. Max Hölz, the most famous guerrilla leader of the Communists was at last defeated and captured early in 1921. In 1923 the strong revolutionary feeling of the Saxons was shown by the proceedings of the Zeigner ministry which depended upon an alliance of Socialists and Communists. It was expelled from office by the Reich Government who occupied the country with troops and replaced the ministry by a coalition of the German People's Party, Democratic Party and right-wing Socialists.

The chief authority for the early history of Saxony is Widukind, whose *Res gestae Saxonicae* is printed, together with the works of other chroniclers, in the *Monumenta Germanica historica, Scriptores.* Collections which may be consulted are: *Codex diplomaticus Saxoniae regiae* (Leipzig, 1862–79); the *Archiv für die sächsische Geschichte,* edited by K. von Weber (Leipzig, 1862–79); the *Bibliothek der sächsische Geschichte und Landeskunde,* edited by G. Buchholz (Leipzig, 1903); and the *Bibliographie der Sächsischen Geschichte* (Leipzig, 1918, *et sqq.,* published by the *Sächsische Kommission für Geschichte*). *See* GERMANY, *bibliography.*

SAXONY, province of, one of the provinces of Prussia, consists mainly of what was formerly the northern part of the kingdom of Saxony, which was ceded to Prussia in 1815, also comprises part of the former duchy of Magdeburg and other districts, the connection of which with Prussia is of earlier date. The area of the province is 9,758 sq.m. For the former kingdom *see* SAXONY, REPUBLIC OF. It is bounded west by Hesse-Nassau, Hanover and Brunswick, north by Hanover and Brandenburg, east by Brandenburg and Silesia, and south by the Republic of Saxony and by Thuringia. It is, however, very irregular in form, entirely surrounding parts of Brunswick and Thuringia, and itself possessing several exclaves, while the northern portion is almost severed from the southern by the Free State of Anhalt.

The major part belongs to the great North-German plain, but the western and south-western districts include parts of the Harz, with the Brocken, its highest summit, and of the Thuringian Forest. About nine-tenths of Prussian Saxony belongs to the basin of the Elbe; the chief feeders of which within the province are the Saale, with its tributary the Unstrut, and the Mulde, but a small district on the west drains into the Weser.

Saxony is on the whole the most fertile province of Prussia and excels all the others in its produce of wheat and beetroot for sugar, but the nature of its soil is very unequal. The best crop-producing districts lie near the base of the Harz Mountains, such as the "Magdeburger Börde" (between Magdeburg and the Saale) and the "Goldene Aue," and rich pasture lands occur in the river valleys, but the sandy plains of the Altmark, in the north part of the province, yield but a scanty return.

Wheat and rye are exported in considerable quantities. The beetroot for sugar is grown chiefly in the district to the north of the Harz, as far as the Ohre, and on the banks of the Saale; and the amount of sugar produced is nearly as much as that of all the rest of Prussia together. Flax, hops and oil-seeds are also cultivated, and large quantities of excellent fruit are grown at the foot of the Harz and in the valleys of the Unstrut and the Saale. The market-gardening of Erfurt and Quedlinburg is well known throughout Germany. The province is comparatively poor in timber, though there are some fine forests in the Harz and other hilly districts. Cattle-rearing is carried on with success in the river valleys, and more goats are met with here than in any other part of Prussia.

The chief rock-salt mines and brine springs are at Stassfurt, Schönebeck and Halle; potash is mined at Stassfurt (*q.v.*). Lignite deposits extend from Oschersleben by Kalbe to Weissenfels; lignite is also found in the neighbourhood of Aschersleben, Bitterfeld and Wittenberg. The copper mines are found chiefly in the Harz district. The other mineral resources include silver, pit-coal, pyrites, alum, plaster of Paris, sulphur, alabaster and several varieties of good building-stone. Numerous mineral springs occur in the Harz.

In addition to the production of sugar the most important industries are the manufactures of cloth, leather, iron and steel wares, chiefly at Erfurt, Suhl and Sömmerda; spirits at Nordhausen, chemicals at Stassfurt and Schönebeck, and starch. Beer is also brewed extensively. Trade is facilitated by the great waterway of the Elbe as well as by a complete system of railways. The chief articles are wool, grain, sugar, salt, lignite and the principal manufactured products named above.

The population of the province of Saxony in 1925 was 3,279,187, an average of 336 persons to the square mile. The bulk of the inhabitants are of unmixed German stock, but many of those in the east part have Wendish blood in their veins.

Prussian Saxony is divided into the three government districts of Magdeburg, Merseburg and Erfurt. The principal towns are Magdeburg, Halle, Erfurt, Halberstadt, Nordhausen, Mühlhausen, Aschersleben, Weissenfels and Zeitz. The university of Halle holds high rank among German seats of learning.

SAXOPHONE, a modern hybrid musical instrument invented by Adolphe Sax, having the clarinet mouthpiece with single reed applied to a conical brass tube. In general appearance the saxophone resembles the bass clarinet, but the tube of the latter is cylindrical and of wood; both instruments are doubled up near the bell, which is shaped somewhat like the flower of the gloxinia. The mouthpiece in both is fixed to a curved tube at right angles to the main bore. In the case of the saxophone, however, owing to its conical bore, the quality of tone materially differs from that of the clarinet. The reed mouthpiece in combination with a conical tube allows the performer to give the ordinary harmonic series unbroken, which means in practice that the octave or second member of the harmonic series is first overblown. The saxophone is therefore one of the class known as octave instruments. The fundamental note given out by the tube when the lateral holes are closed is that of an open organ pipe of the same length, whereas when, as in the clarinet family, the reed mouthpiece is combined with a cylindrical bore, the tube behaves as though it were closed at one end, and its notes are an octave lower in pitch. Hence the bass clarinet to give the same note as a bass saxophone would need to be only half as long. The quality of tone of this family of instruments is inferior to that of the clarinets and has affinities with that of the harmonium. According to Berlioz it had kinship also with the timbre of the 'cello and cor anglais, with, however, a brazen tinge. The saxophone has not enjoyed much favour hitherto with high-class composers, though Richard Strauss scored for a quartet of the instruments in his Sinfonia Domestica. In military bands, however, it has proved of great service while in recent years it has acquired extraordinary vogue as a leading member of the jazz orchestra.

SAY, JEAN BAPTISTE (1767–1832), French economist, was born at Lyons, on Jan. 5, 1767, of a Protestant family, who had fled from France after the Revocation of the Edict of Nantes, but had returned in the 18th century. Intending to follow a commercial career, Say first entered the house of an English merchant, and was later employed in the office of a life assurance company in France. His attention having been called to *The Wealth of Nations,* however, he began to study economics, and in 1789 published his first pamphlet. In 1803 he published his principal work *Traité d'économie politique.* His views being displeasing to Napoleon, he was dismissed from the post of tribune, to which he had been elected in 1799. He built a spinning mill, and devoted himself to the industry and to the revision of his book, of which the second edition appeared in 1814. In the same year he was sent by the French Government to study the economic conditions of Great Britain. The results of his observations appeared in a tract, *De l'Angleterre et des Anglais,* and in the corrected edition of the *Traité* (1817). A chair of industrial economy

was founded for him in 1819 at the Conservatoire des Arts et Métiers. In 1831 he was made professor of political economy at the Collège de France, and in 1828–30 he published his *Cours complet d'économie politique pratique*. At the revolution of 1830 he was named a member of the council-general of the department of the Seine, but found it necessary to resign. He died at Paris on Nov. 15, 1832.

Say's writings occupy vols. ix.–xii. of Guillaumin's *Collection des principaux économistes*. Among them are *Olbie, où essai sur les moyens de reformer les moeurs d'une nation* (1800); *Catéchisme d'économie politique* (1815); *Petit Volume contenant quelques aperçus des hommes et de la société, lettres à Malthus sur différens sujets d'économie politique* (1820); *Épitomé des principes de l'économie politique* (1831). A volume of *Mélanges et correspondance* was published posthumously by his son-in-law, Chas. Comte, author of the *Traité de législation*.

The last edition of the *Traité d'économie politique* which appeared during the life of the author was the 5th (1826); the 6th, with the author's final corrections, was edited by the eldest son, Horace Emile Say, himself known as an economist, in 1846. The work was translated into English by C. R. Prinsep (1821), and into German, by C. Ed. Morstadt (1818 and 1830). *See* also A. Liesse, *Jean Baptiste Say* (Paris, 1901).

SAY, JEAN BAPTISTE LÉON (1826–1896), French statesman and economist, the grandson of J. B. Say (*q.v.*) and the son of Horace Émile Say (1794–1860), was born in Paris on June 6, 1826. Descended from a long line of distinguished economists, Léon Say established his reputation by his brilliant criticisms of Haussmann's financial administration of the Seine, published in the *Journal des Débats* of which he was one of the proprietors. On taking his seat in the Assembly of 1871 for the Seine, he was chosen as reporter of a commission on the state of the national finances. The statements which he published attracting the attention of Thiers he appointed Say prefect of the Seine (June 5), and in December 1872 promoted him minister of finance. This was a remarkable tribute from Thiers, who, as a protectionist, was opposed to Say's free trade views. After the fall of Thiers (May 1873), Say held office in the Buffet ministry, although in profound disagreement with its leaders, and was minister of finance under Dufaure and Jules Simon, in the Dufaure ministry of Dec. 1877, and in the Waddington ministry till Dec. 1879. During this period, in which he was practically the autocratic ruler of the French finances, he directed the payment of the war indemnity with consummate skill, completing it long before the prescribed time.

Say's general financial policy was to ameliorate the incidence of taxation and to enrich the country, and therefore the Treasury, by removing all restrictions on internal commerce. He accordingly reduced the rate of postage, repealed the duties on many articles of prime utility, such as paper, and fought strongly, though unsuccessfully, against the system of *octrois*. In 1880 he visited England to negotiate a commercial treaty between France and England, but the presidency of the Senate falling vacant, he was elected to it on May 25, having meanwhile secured a preliminary understanding. In Jan. 1882 he became minister of finance in the Freycinet cabinet, which was defeated in the following July on the Egyptian question. Say's influence waned before the attacks of Socialism and the revival of protectionism, against which Say vainly organized the *Ligue contre le renchérissement du pain*. He had, however, a large share in the successful opposition to the income-tax. In 1889 he quitted the Senate to enter the Chamber as member for Pau, in the belief that his efforts for Liberalism were more urgently needed in the popular assembly. Throughout his career he was an indefatigable writer and lecturer on economics, and in both capacities exerted a wide influence. Special mention must be made of his work, as editor and contributor, on the *Dictionnaire des finances* and *Nouveau Dictionnaire d'économie politique*.

Say's style was easy and lucid, and he was often employed in drawing up important official documents, such as the famous presidential message of Dec. 1877. He was for many years a prominent member of the Académie des Sciences Morales et Politiques, and in 1886 succeeded to Edmond About's seat in the Académie Française. He died in Paris on April 21, 1896. A selection of his most important writings and speeches has since been published in four volumes under the title of *Les Finances de la France sous la troisième république* (1898–1901).

See Georges Michel, *Léon Say* (Paris, 1899); Georges Picot, *Léon Say, notice historique* (Paris, 1901), with a bibliography.

SAY, a town on the right bank of the river Niger in 13° 4′ N. and 2° 30′ E. In the agreement of 1890 between Great Britain and France for the delimitation of their respective spheres of influence in West Africa, Say was taken as the western end of an imaginary line which ran eastward to Barrua on Lake Chad. By the convention of 1898 Say and a considerable tract of territory south and east of the town were ceded to France. The district of Say covers 18,500 square kilometres and has 69,000 inhabitants; after having formed part of the colony of the Upper Volta, it was again attached in 1927 to that of Nigeria (*q.v.*).

SAYAD, a descendant of Ali, the son-in-law of Mohammed, by Fatima, Mohammed's daughter. Many of the Pathan tribes in the North-West Frontier Province of India, such as the Bangash of Kohat and the Mishwanis of the Hazara border, claim Sayad origin. The apostles who completed the conversion of the Pathans to Islam were called Sayads if they came from the west, and Sheikhs if they came from the east; hence doubtless many false claims to Sayad origin. In Afghanistan the Sayads have much of the commerce in their hands, as their holy character allows them to pass unharmed where other Pathans would be murdered.

The Sayads gave a short-lived dynasty to India, which reigned at Delhi during the first half of the 15th century. Their name again figures in Indian history at the break up of the Mogul empire, when two Sayad brothers created and dethroned emperors at their will (1714–1720).

SAYAN MOUNTAINS, in Central Asia, forming the eastern continuation of the Sailughem or Altai range, stretching from 89° E. to 106° E. They are the border-ridge between the plateau of N.W. Mongolia and Siberia. The geology is imperfectly known; the mountains are of the Hercynian age. The general elevation is 7,000 to 9,000 ft.; peaks, consisting largely of granites and metamorphic rocks, reach 10,000 ft. and 11,450 ft., *e.g.*, in Munko Sardyk; and the principal passes lie at 6,000 to 7,500 ft. above the sea, *e.g.*, Muztagh 7,480 ft., Mongol 6,500 ft., Tenghyz 7,480 ft. and Obo-sarym 6,100 ft. In 92° E. the system is pierced by the Bei-kem or upper Yenisei, and in 106° E., it terminates above the depression of the Selenga-Orkhon valley. From the Mongolian plateau the ascent is gentle, but from the plains of Siberia it is much steeper, despite the fact that the range is masked by a broad belt of subsidiary ranges, *e.g.*, the Usinsk, Oya, Tunkun, Kitoe and Byelaya ranges. Between the breach of the Yenisei and the Kosso-gol (lake) in 100° 30′ E. the system bears also the name of Yerghik-taiga. The flora is poor, although the higher regions carry good forests of larch, pitch pine, cedar, birch and alder, with rhododendrons and species of *Berberis* and *Ribes*. Lichens and mosses clothe many of the boulders that are scattered over the upper slopes.

SAYBROOK, a town of Middlesex county, Connecticut, U.S.A., on Long Island sound, at the mouth of the Connecticut river; served by the New York, New Haven and Hartford railroad and steamboat lines. Pop. (1930), 2,381. It is a beautiful place, with several old buildings, notably the mansion built about 1783 by Capt. Elisha Hart. Deep River, the principal village, has manufactures of ivory and bone and various other articles. In the adjoining town of Old Saybrook is Fenwick, the smallest borough in the State, with a population in 1920 of 13. The first settlement on Saybrook point was made late in 1635 (forestalling by a few weeks an attempted settlement by the Dutch) by John Winthrop, for a company with a grant from the Earl of Warwick, of which Lord Saye and Sele, Lord Brooke, Sir Richard Saltonstall, John Pym and John Hampden were the largest shareholders. A palisade across the narrowest part of the neck and a fort were built, and the names of the two principal proprietors were combined to make a name for the settlement. In 1644 the proprietors' rights were sold to Connecticut. The Collegiate School of Connecticut, established here in 1701 and moved to New Haven in 1716, was the foundation of Yale university. In 1708 a Congregational Synod met here and drew up the Saybrook platform of church discipline, which continued in full force until 1784. Say-

brook was the home of David Bushnell (1742–1824) who in 1776 devised a submarine torpedo and a tortoise-shaped diving boat ("the American Turtle"), which were tried against the British without success in the Revolutionary War.

SAYCE, ARCHIBALD HENRY (1845–), British Orientalist, was born at Shirehampton on Sept. 25, 1845, son of the Rev. H. S. Sayce, vicar of Caldicot. He was educated at Bath, and at Queen's college, Oxford, becoming a fellow in 1869. From 1891 to 1919 he was professor of Assyriology at Oxford. Although his conclusions have been modified (*e.g.*, in chronology and transliteration) by the work of other scholars (see, *e.g.*, BABYLONIA AND ASSYRIA), it is impossible to overestimate his services to Oriental scholarship. He travelled widely in the East. There has been a strong tendency to revert to the views which he advanced on the question of the Hittites in his early Oxford lectures. He was a member of the Old Testament Revision company (1874–84); deputy professor of comparative philology in Oxford (1876–90); Hibbert lecturer (1887); Gifford lecturer (1900–02).

Among his more important works are: *Assyrian Grammar for Comparative Purposes* (1872); *Principles of Comparative Philology* (1874); *Babylonian Literature* (1877); *Introduction to the Science of Language* (1879); *Monuments of the Hittites* (1881); *Herodotus i.–iii.* (1883); *Patriarchal Palestine* (1895); *The Egypt of the Hebrews and Herodotus* (1895); *Early History of the Hebrews* (1897); *Israel and the Surrounding Nations* (1898); *Babylonians and Assyrians* (1900); *Egyptian and Babylonian Religion* (1903); *Archaeology of the Cuneiform Inscr.* (1907). He also contributed important articles to the 9th, 10th and 11th editions of the *Encyclopædia Britannica* and edited a number of Oriental works. *See* also his *Reminiscences* (1923).

SAYE AND SELE, WILLIAM FIENNES, 1ST VISCOUNT (1582–1662), was the only son of Richard Fiennes, 7th Baron Saye and Sele, and was descended from James Fiennes, Lord Saye and Sele, who was lord chamberlain and lord treasurer under Henry VI. and was beheaded by the rebels under Jack Cade on July 4, 1450. Fiennes was educated at New College, Oxford; he succeeded to his father's barony in 1613, and in parliament opposed the policy of James I., undergoing a brief imprisonment for objecting to a benevolence in 1622, and he showed great animus against Lord Bacon. In 1624, he was advanced to the rank of a viscount. In the early parliaments of Charles I. he was in Clarendon's words "the oracle of those who were called Puritans in the worst sense, and steered all their counsels and designs." His energies found a new outlet in helping to colonize Providence Island, and in interesting himself in other and similar enterprises in America. Although Saye resisted the levy of ship-money, he accompanied Charles on his march against the Scots in 1639; but, with only one other peer, he refused to take the oath binding him to fight for the king to "the utmost of my power and hazard of my life." When the Civil War broke out, however, Saye was on the committee of safety, was made lord-lieutenant of Gloucestershire, Oxfordshire and Cheshire, and, raising a regiment, occupied Oxford. He was a member of the committee of both kingdoms; was mainly responsible for passing the self-denying ordinance through the House of Lords; and in 1647 stood up for the army in its struggle with the parliament. In 1648, both at the treaty of Newport and elsewhere, Saye was anxious that Charles should come to terms, and he retired into private life after the execution of the king, becoming a privy councillor again upon the restoration of Charles II. He died at his residence, Broughton Castle near Banbury, on April 14, 1662. On several occasions Saye outwitted the advisers of Charles I. by his strict compliance with legal forms. He was a thorough aristocrat, and his ideas for the government of colonies in America included the establishment of an hereditary aristocracy. Saybrook (*q.v.*) in Connecticut is named after Viscount Saye and Lord Brooke.

SAYERS, TOM (1826–1865), English pugilist, was born at Brighton on May 25, 1826. By trade a bricklayer, he began his career as a prize fighter in 1849 and won battle after battle, his single defeat being at the hands of Nat Langham in Oct. 1853. In 1857 he gained the championship. His fight with the American, John C. Heenan, the Benicia Boy, a much heavier man than himself, is perhaps the most famous in the history of the English prize ring. It took place at Farnborough on April 17, 1860, and lasted 2 hr. 6 min., 37 rounds being fought. After Sayers's right arm had been injured the crowd pressed into the ring and the fight was declared a draw; £3,000 was raised by public subscription for Sayers, who withdrew from the ring. He died on Nov. 8, 1865. The champion was 5 ft. 8½ in. in height and his fighting weight was under 11 stone. An account of the fight between Sayers and Heenan is given by Frederick Locker-Lampson in *My Confidences* (1896).

SAYRE, a borough of Bradford county, Pennsylvania, U.S.A., on the Susquehanna river at the mouth of the Chemung, 17 m. S.E. of Elmira and just south of the New York State line. It is served by the Lehigh Valley railroad, inter-urban trolleys and motor-bus lines. Pop. (1920) 8,078 (91% native white); 1930, Federal census 7,902. Adjoining Sayre are the Pennsylvania boroughs of Athens and South Waverly (4,384 and 1,251 respectively in 1920) and the New York village of Waverly (*q.v.*); the four municipalities are practically one industrial community. Sayre was founded in 1880 and incorporated in 1891. It was named for Robert Heysham Sayre (1824–1907), chief engineer of the railroad for many years.

SAYYID AHMAD KHAN, SIR (1817–1898), Mohammedan educationist and reformer, was born at Delhi, India, in 1817. He belonged to a family which had come to India with the Mohammedan conquest, and had held important offices under the Mogul emperors. Although his imperfect acquaintance with English prevented his attainment of higher office than that of a judge of a small cause court, he earned the title of the recognized leader of the Mohammedan community. To the British he rendered loyal service, and when the mutiny reached Bijnor in Rohilkand in May 1857 the British residents owed their lives to his courage and tact. Sayyid Ahmad established a translation society, which became the Scientific Society of Aligarh, and encouraged the study of western life and letters. In 1873 he founded the Mohammedan Anglo-Oriental College at Aligarh. He stimulated a similar educational activities in Karachi, Bombay and Hyderabad. Thus he effected a revolution in the attitude of Mohammedans towards modern education. He was made K.C.S.I. and became a member of the legislative councils of India and Allahabad, and of the education commission. He died at Aligarh on March 2, 1898.

See Lieut.-Colonel G. F. I. Graham, *The Life and Work of Sir Saiyad Ahmed Khan* (1885).

SAZONOV, SERGHEI DMITRIEVICH (1866–1927), Russian statesman, was born in the province of Ryazan, July 29, 1866, the son of a landed proprietor, and educated at the Alexandrovsky Lyceum, St. Petersburg (Leningrad), a high school for the sons of noblemen destined mainly for the civil service. Having occupied various diplomatic posts in Rome and served six years in the Russian Embassy in London he was promoted, in 1906, to be Minister-Resident at the Vatican, where his engaging manners, frankness and taste for ecclesiastical affairs enabled him to make great headway. In 1909 he entered the Ministry of Foreign Affairs as coadjutor to Izvolsky, whom he succeeded as Minister in 1910—an appointment ascribed to the influence of his brother-in-law, Stolypin.

Sazonov's line of action was definitely traced for him by the European situation on the one hand and by the limitation of his rôle to that of confidential secretary to the Emperor on the other. His chief functions were to parry Austria's fitful thrusts at Serbia, to curb Serbia's explosive impatience, buoying her up with hopes of a vast legacy to fall due on the death of the Emperor Francis Joseph, and to bespeak the help of England, Italy, Rumania (to whom he also held out hopes of a legacy) and Bulgaria in the coming struggle. These tasks exceeded his powers, and his abortive Near-Eastern policy did not prevent Russia's ruinous collapse during the World War. Yet if his work was not to prove permanent he carried it out with considerable skill, and defended himself ably in his memoirs against the charge that he was seeking to precipitate a World War; although he admitted knowledge of the fact that Hartwig, in Belgrade, was working against his avowed aims. Meanwhile, Sazonov genuinely worked for present peace, to gain time for Stolypin's far-reaching domestic reforms and to allow Russia to consolidate her insecure

domestic and military situation.

The arrangements come to during the Tsar's visit to Potsdam (Nov. 4–5 1910) and the Kaiser's return visit to Wolfsgarten (Nov. 11) respecting the Baghdad railway, North Persia and the maintenance of Turkey, eased the strain, but failed to dispel the atmosphere of mistrust. Sazonov was suspected of a lack of straightforwardness by the Kaiser. Russia's diplomatic representatives abroad were largely to blame for this, and in particular the rashness or awkwardness of ambassador Charykov in Constantinople, who secretly proposed to guarantee that city to Turkey and protect her from all attacks by the Balkan States in return for the freedom of the Straits. Other covert moves also lent colour to the charges of underhand dealing. For example, on the conclusion of the Balkan Alliance of 1912, Sazonov decided to seek Germany's help in overawing the Balkan States and thus preserving peace. He accordingly arranged an interview between the Tsar and the Kaiser at Baltischport on July 4–5 1912, which was followed by a three days' exchange of views between the German Chancellor and the members of the Russian Govt. in St. Petersburg. Yet he concealed from Germany the existence of the Balkan Alliance which had been communicated to him. Sazonov next repaired to London, Paris and Berlin and the Great Powers authorised him and Berchtold to announce their determination to uphold the *status quo*, so that if the Balkan States broke the peace their victory would be fruitless. The veto was successfully ignored by the Balkan Powers, and a European crisis was the result. Sazonov, on this occasion, behaved with moderation. He kept a tight hand on Serbia, obliged her to content herself with a railway harbour on the Albanian coast, a railway connection and the secret assurance that her "promised land" lay within the dual monarchy.

He was next employed in drafting, in collaboration with Bethmann Hollweg, a scheme of reforms for Armenia (Nov. 5, 1913). Immediately afterwards, a fresh conflict with Germany arose over the despatch of General Liman von Sanders to Constantinople. Sazonov gave vent to his dissatisfaction in unusually strong terms, but on the Kaiser ordering Liman to lay down the command of the first Turkish army corps, while retaining his other functions, Nicholas II. let the matter drop. Sazonov then drafted a memorandum to the Tsar on Russia's claim to the freedom of the Straits (Nov. 1913) and three months later (Feb. 21, 1914) convened a council of political and military experts to discuss the ways and means of realising the scheme in case of a European war. But the military experts announced that in the plans of campaign no such side-problems could be included.

On learning of the delivery of the Austro-Hungarian ultimatum to Serbia on July 24, 1914, Sazonov appealed unsuccessfully to Austria to extend the time limit, and advised Serbia to accept all demands except those concerning the sovereign rights of Serbia. Meanwhile, Russia adopted the military measures known as "premobilisation" (July 25), the Tsar and Sazonov planning a partial mobilisation to follow in case Serbia should be attacked. But the General Staff objected that it had no plan ready for a transition from partial to general mobilisation, and that as war seemed unavoidable the latter was imperative. Sazonov still insisted on waiting; meanwhile Berchtold declared war against Serbia (July 28), whereupon Sazonov (in the night of July 28–29) advised the Tsar to sign the order.

A belated telegram, however, from the Kaiser adjuring him to preserve peace for the sake of the monarchic principle moved the Tsar to withdraw the order for general, and substitute that for partial, mobilisation. This command was obeyed in words but the military experts having convinced Sazonov that it would be suicidal, the Minister next morning (July 30) presented himself to the Tsar and obtained his consent to the radical measure advocated by the General Staff. On the following morning this order was posted up in St. Petersburg and the catastrophe, already inevitable, broke loose.

During the War Sazonov countered all influences tending to the abandonment of the struggle by Russia, but he followed the Tsar's lead in demanding first the opening of the Straits and the internationalisation of Constantinople and later on the annexation of the Turkish capital. The hostility of Turkey and Bulgaria impeded assistance from the Allies, whereupon Sazonov made a bid for the help of the Poles in the shape of a Home Rule scheme, but the proposal was scouted in Court circles and he was dismissed from his post. Thus ended his career. His fall was gently broken by his appointment as Ambassador to Great Britain, but before he reached his destination the revolution of March 1917 had deposed the Tsar. Sazonov, however, was willing to represent the Government that had thrust aside his imperial master but it too was suddenly swept away. He was next appointed Minister for Foreign Affairs by Admiral Kolchak; but after 1920 he retired into private life, settling at Versailles, where he occupied himself in writing his memoirs. These appeared in English in 1928 under the title "Fateful Years." They were attacked, especially in Germany, on the ground of insincerity. (*See* the work *Rings um Sazonov:* 1928.) Sazonov died at Nice, Dec. 23, 1927.

SBEITLA (anc. *Sufetula*), a ruined city of Tunisia, 66 m. S.W. of Kairawan. The chief ruin is the Forum, 238 ft. by 198 ft., having three small and one large entrance. The great gateway is a fine monumental arch in fair preservation, with an inscription to Antoninus Pius. Facing the arch, their rear walls forming one side of the enclosure, are three temples, connected with one another by arches, and forming one design. The length of the entire façade is 118 ft. The principal chamber of the central temple, which is of the Composite order, is 44 ft. long; those of the side temples, in the Corinthian style, are smaller. The walls of the middle temple are ornamented with engaged columns; those of the other buildings with pilasters. The porticos have been repaired, and run round the other three sides of the enclosure, which is still partly paved. The other ruins include baths, remains of a theatre, an amphitheatre, a triumphal arch of Diocletian, two churches of the priest Servas and the bishop Bellator, a chapel of the bishop Jucundus (411–419), a still serviceable bridge which also carried an aqueduct, and several square Byzantine forts.

The early history of Sufetula is preserved only in certain inscriptions. Under Antoninus and Marcus Aurelius it was a flourishing city, the district, now desolate, being then very fertile and covered with forests of olives. It was partly rebuilt during the Byzantine occupation and became a centre of Christianity. At the Arab invasion it was the capital of the exarch Gregorius.

See A. Merlin, *Forum et églises de Sufetula* (1912).

SCABIES or **ITCH,** a skin disease due to an animal parasite, the *Acarus* or *Sarcoptes scabiei* (*see* MITE), which burrows under the epidermis at any part of the body, but hardly ever in the face or scalp of adults; it usually begins at the clefts of the fingers, where its presence may be inferred from several scattered pimples, which will probably have been torn at their summits by the scratching of the patient, or have been otherwise converted into vesicles or pustules. The remedy is soap and water, and sulphur ointment.

SCABIOUS, the common name for several European flowers. The common or field scabious (*Knautia arvensis*) and the devil's-bit scabious (*Scabiosa succisa*) belong to the teazel family (Dipsacaceae). The flowers are aggregated together to form a head. The sheep's-bit scabious (*Jasione montana*) belongs to the bell-flower family (Campanulaceae) and is a quite different plant. It resembles the common scabious, however, in having the flowers aggregated together into a head.

SCAEVOLA, the name of a famous family of ancient Rome, the most important members of which were:—

1. GAIUS MUCIUS SCAEVOLA, a legendary hero, who volunteered to assassinate Lars Porsena when he was besieging Rome. He reached Porsena's tent, but slew his secretary by mistake. Before the royal tribunal Mucius declared that he was one of 300 noble youths who had sworn to take the king's life, and that he had been chosen by lot to make the attempt first. Threatened with death or torture, Mucius thrust his right hand into the fire blazing upon an altar, and held it there until it was consumed. The king, deeply impressed and dreading a further attempt upon his life, ordered Mucius to be liberated, made peace with the Romans and withdrew his forces. Mucius was rewarded with a grant of land beyond

the Tiber, known as the "Mucia Prata" in the time of Dionysius of Halicarnassus, and received the name of Scaevola ("left-handed"). The story is presumably an attempt to explain the name Scaevola (Livy ii. 12; Dion. Halic. v. 27–30). The Mucius of the legend is described as a patrician; the following were undoubtedly plebeians.

2. Publius Mucius Scaevola, Roman orator and jurist, consul 133 B.C. during the time of the Gracchan disturbances. He was not opposed to moderate reforms, and refused to use violence against Tiberius Gracchus. After the murder of Gracchus, however, he expressed his approval of the act. He was an opponent of the younger Scipio Africanus, for which he was attacked by the satirist Lucilius (Persius i. 115; Juvenal i. 154). In 130 he succeeded his brother Mucianus as *pontifex maximus.* During his tenure of office he published a digest in 80 books of the official annals kept by himself and his predecessors. Cicero frequently mentions him as a lawyer of repute, and he is cited several times in the Digest. He was also a famous player at ball and the game called Duodecim Scripta; after he had lost a game, he was able to recall the moves and throws in their order.

See A. H. J. Greenidge, *History of Rome.*

3. Quintus Mucius Scaevola, son of (2), usually called *"Pontifex Maximus,"* to distinguish him from (4), consul in 95 B.C. with L. Licinius Crassus the orator. He and his colleague brought forward the *lex Licinia Mucia de civibus regundis* which closed Roman citizenship to the allies in future, and was largely responsible for the Social War. After his consulship Scaevola was governor of the province of Asia, and dealt severely with the tax-farmers. In honour of his memory the Greeks of Asia set aside a day for the celebration of festivities and games called Mucia. He was subsequently appointed *Pontifex Maximus,* and, in accordance with custom, dispensed free legal advice, which was extensively sought, even by men of the standing of Servius Sulpicius. He regulated the priestly colleges, and insisted on observance of the traditional ritual, though he himself believed that religion was only for the uneducated. He was proscribed by the Marian party, and in 82, when the younger Marius, after his defeat by Sulla at Sacriportus, gave orders for the evacuation of Rome and the massacre of the chief men of the opposite party, Scaevola, while attempting to reconcile the opposing factions, was slain at the altar of Vesta and his body thrown into the Tiber. He had already escaped an attempt made upon his life by Gaius Fimbria at the funeral of the elder Marius in 86.

Scaevola was the founder of the scientific study of Roman law and the author of a systematic treatise on the subject, in eighteen books, frequently quoted and followed by subsequent writers. It was a compilation of legislative enactments, judicial precedents and authorities, from older collections, partly also from oral tradition. A small handbook called Ὅροι (*Definitions*) is the oldest work from which any excerpts are made in the *Digest,* and the first example of a special kind of judicial literature (*libri definitionum* or *regularum*). It consisted of short rules of law and explanations of legal terms and phrases. A number of speeches by him, praised by Cicero for their elegance of diction, were in existence in ancient times.

4. Quintus Mucius Scaevola (*c.* 159–88 B.C.), uncle of (3), from whom he is distinguished by the appellation of *"Augur."* He was instructed in law by his father, and in philosophy by the Stoic Panaetius of Rhodes. In 121 he was governor of Asia. Accused of extortion on his return, he defended himself successfully. In 117 he was consul. He was a great authority on law, and at an advanced age he gave instruction to Cicero and Atticus. He had a high appreciation of Marius, and refused to vote for Sulla's motion declaring him a public enemy. Scaevola is one of the interlocutors in Cicero's *De oratore, De amicitia* and *De republica.*

For the legal importance of the Scaevolas, *see* A. Schneider, *Die drei Scaevola Ciceros* (Munich, 1879), with full references to ancient and modern authorities.

SCAFELL (pronounced and sometimes written Scaw Fell), a mountain of Cumberland, England, in the Lake District. The name is specially applied to the southern point (3,162 ft. in height) of a certain range or mass, but Scafell Pike, separated from Scafell by the steep narrow ridge of Mickledore, is the highest point in England (3,210 ft.). The ridge continues north-east to Great End (2,984 ft.), which falls abruptly to a flat terrace, on which lies Sprinkling Tarn. The range thus defined may be termed the Scafell mass. North-west from the Pike the lesser height of Lingmell (2,649 ft.) is thrown out, and the steep flank of the range sweeps down to the head of Wasdale. On the east an even steeper wall, with splendid crags, falls to Eskdale. Above Mickledore ridge Scafell rises nearly sheer, with bold clefts.

SCAFFOLD or **SCAFFOLDING,** properly a platform or stage, particularly one of a temporary character erected for viewing or displaying some spectacle. The most general modern application of the word, however, refers to the temporary frames and platforms erected or suspended at convenient heights to afford easy access to work of construction and repair.

A scaffold, in its simplest form, may be a single plank supported by trestles, or it may be the extremely complicated construction necessary to render every part of a large cathedral or similar building accessible.

Up to a comparatively recent date scaffolds were invariably constructed of timbers bound together with ropes, but now many forms of patent scaffolding and fixing devices are available. The more general adoption of steel-framed buildings has contributed largely towards the development of *suspended scaffolding.* The steel members themselves, supplemented by ladders, provide the only scaffolding necessary in the erection of the frame, and since the steel work is practically completed before the wall filling and facing is commenced, it is more convenient and economical to suspend a single platform—that may extend along the whole face of the building if required, and capable of being raised as the work proceeds—from cantilevers fixed to the top members of the frame, than it is to erect a poled scaffold over the whole face of the building.

Timber Scaffolds.—The ordinary type of timber scaffolding comprises the following:—standards, ledgers, putlogs, braces, scaffold boards and lashings. The standards, ledgers and braces are usually tapering poles (the stripped trunks of young fir trees), about 15 to 35 ft. in length and 3½ to 5 in. in diameter at the butt.

The putlogs are of riven birch, 5 to 6 ft. long and 3 in. in section. Scaffold boards are of spruce, 8 to 12 ft. long, 9 in. wide by 1½ in. thick, with the ends bound by hoop iron to obtain strength and security. The ends of the hoop iron should be turned into saw cuts in the edges of the wood to prevent injury to the workmen while handling the boards.

Until recently the lashings were, in nearly every case, made of jute or hemp fibres, white Manila hemp being the best and strongest. Flexible wire cords are now used to a considerable extent for lashings. These cords are about ¼ in. in diameter and are sufficiently long for every form of scaffold junction. They are made of several strands of small gauge wire, one end of the cord being finished with a metal cap or sleeve to prevent the strands from spreading, the other end being turned around a metal eye piece and securely bound or spliced. Scaffold wedges are unnecessary with wire cords.

Chain ties and tightening blocks are frequently used in the place of cord lashings and require less time for fixing. Such a form of scaffold fixing was used in the scaffolding erected for the reconstruction of Buckingham palace, and in many other important works, and proved to be satisfactory.

Bricklayer's Scaffold.—In erecting a bricklayer's scaffold, the standards are placed upright at a distance of 5 ft. from the face of the wall and from 6 to 9 ft. apart; the lower ends of the standards being held in position by the method best suited to the nature of the site. Thus, the ends may be placed in barrels of earth or sand, they may be placed on a timber sole plate and held in position by nailed fillets; or they may be sunk a foot or two into the ground. The ledgers are fixed horizontally along the inner faces of the standards at vertical intervals of 5 feet. The putlogs are placed 3 or 4 ft. apart, perpendicular to the face of the wall, one end of each putlog resting on the ledger, the other end passing into a recess left, or made, in the wall for that purpose. The scaffold boards are laid on the putlogs and parallel to the face of the wall. At the position where the end joints between the boards occur, two putlogs are placed a few inches

apart to obviate the necessity for lapping the ends of the boards.

Scaffolds of this type should always have diagonal braces fixed across the faces of the standards to avoid risk of failure by side racking, and the scaffold must be prevented from falling away from the face of the wall by ties or bridles through the window openings. The third possible cause of failure, the buckling of the standards, is guarded against in scaffolds supporting heavy loads by having the whole or lower part of the scaffold "double poled." All scaffolds should have guard planks and guard rails fixed to the outer standards.

As the work is carried up the boarding and many of the putlogs are removed to the stage above, some putlogs, however, being left tied to the lower ledgers to stiffen the scaffold. In the case of thick walls a scaffold is required inside as well as outside the building, and when this is the case the two structures are tied together and stiffened by short connecting poles through the window and door openings.

Mason's Scaffold.—The mason requires an independent scaffold. He may not rest the inner ends of his putlogs in the wall as the bricklayer does, for this would disfigure the stonework, hence another and parallel framework of standards and ledgers is placed within a few inches of the wall-face upon which to support them. The two portions are tied together with cross braces, and the whole of the timbering is made capable of taking heavier weights than are required in the case of the bricklayer.

Masons' scaffolds upon which banker work is done are usually of sawn material bolted together; the arrangement of the rectangular members corresponding to that in the ordinary type of scaffold.

Metal or Tubular Scaffold.—This type of scaffolding was used during the process of erection of Bush house, Aldwych, Devonshire house, Piccadilly and many other important buildings in London and the provinces, and must now be noticed in any reference work on scaffolding.

The special advantages claimed for tubular scaffolding are:—It is easily transported; since 12 feet is the maximum length of any member a great quantity may be stored in an ordinary truck. Its strength is beyond question, it is fireproof and practically indestructible. It is easily introduced into narrow or tortuous entrances, and may be erected with great rapidity and little labour. It is not affected by climatic conditions, is neat and compact when erected and is light and efficient for slung scaffolds.

Tubular scaffolding consists of sections of steel tubes, about 2 in. in diameter and of various lengths, with various forms of clips and couplings, base plates and patent putlogs.

The putlogs are of oak reinforced with steel, the steel projecting beyond the wood to allow it to be inserted and wedged into the brickwork joints when necessary. Thus putlog holes are not required to be left or made in the wall surfaces. The standards are not placed more than 8 feet apart for ordinary scaffolds, and not more than 6 feet apart for masons' scaffolds. The diagonal bracing is fixed by special swivel couplers.

Suspended Scaffolding.—Where the nature of the building will permit of its use suspended scaffolding has many very important advantages. Thus, in high steel framed buildings the lower floors may be occupied before the upper ones are completed. The scaffold platform may be kept at the position in which the work is always at bench height. The space immediately below the scaffold is clear of obstructions. The scaffold platform is flexible and its height may be varied along its length, within certain limits, to suit special conditions.

This form of scaffolding was used in Adelaide House, London, E.C.; the Lewis Building, Birmingham; Messrs. C. and A. Modes Ltd., Liverpool, and many other equally large and important buildings, and has proved to be safe, convenient and economical. The complete scaffold is made up of a number of units or sections.

Each section has a machine or winch at each corner, the supporting cables being wound or unwound about the machine drum by a device specially designed to ensure safety while raising or lowering the platform.

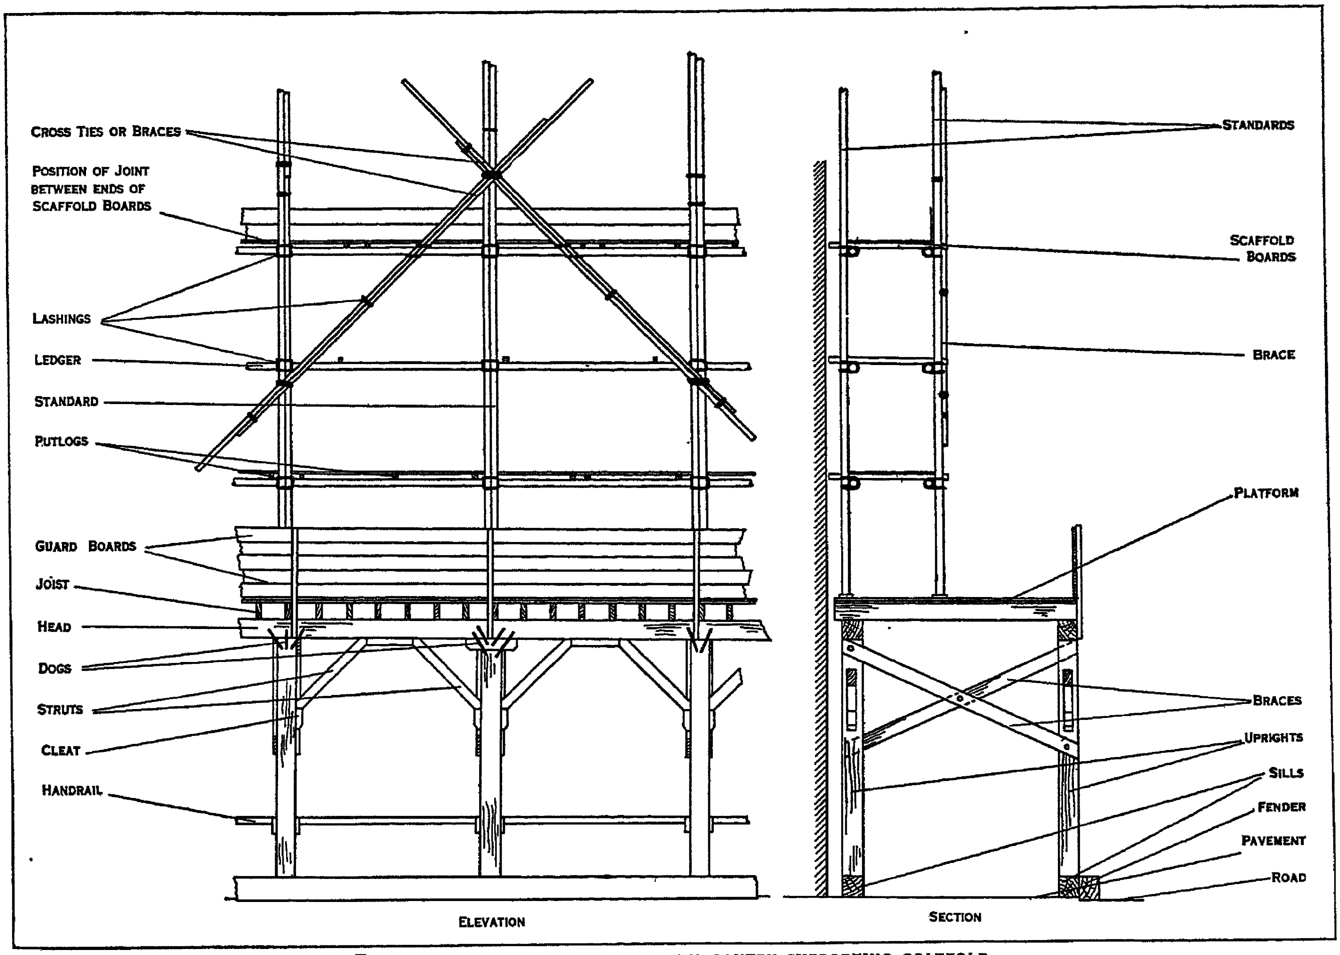
Gantries.—"Gantry" is the term applied to a staging of squared timber used for the easy transmission of heavy material. The name has, however, come to be used generally for strong stagings of squared timber whether used for moving loads or not. Taking the general meaning of the term, gantries may be divided into three classes: (1) Gantries supporting a traveller; (2) Travelling gantries, in which the whole stage moves along rails placed on the ground: (3) Elevated platforms which serve as a base upon which to erect pole scaffolding.

The two former of this type of structure are now little used. Many more or less permanent timber gantries exist in goods yards and similar places but modern methods of handling and hoisting materials have rendered the old type of traveller gantry almost obsolete.

The form of fixed staging or platform gantry which is used over a public pavement is indispensable for conducting building operations in large towns where it is important to keep the footway clear and to safeguard pedestrians who are using the footway in front of the building site. They consist of two sets of standards, sill and head, one set being erected close to the building and the other about 8 or 10 ft. away. These stages are formed of square timber, framed and braced in a similar manner to gantries designed to support a traveller, but, instead of external shores or braces the uprights are braced across to each other, care being taken to fix the braces at such a height as to allow free passage beneath them. Joists are placed across from head to head, and a double layer of scaffold boards is laid to form the floor, the double thickness being necessary to prevent materials dropping through the joints upon the heads of passers-by. When the gantry abuts on the road, a heavy timber fender splayed at each end should be placed so as to ward off the traffic. At the level of the platform a fanguard is often thrown out for a distance of about 6 ft. or more and closely boarded to protect the public from falling materials and the workmen from accident.

Derrick Towers.—Derrick "gantries" or "towers" are skeleton towers of heavy timbers erected in a central position on a site to support a platform at such a height as to enable an electric or steam power derrick crane placed upon it to clear the highest portions of the building. The crane revolves upon a base through nearly three parts of the circumference of a circle, and in addition to this the jib of the crane is capable of an "up and down" motion which enables it to command any spot within a radius of three-quarters of the length of the jib. For a single crane, a derrick tower with three legs is built, and the crane is placed over one of these, stayed back to the other two and then counterbalanced by heavy weights. Each leg is usually from 6 ft. to 10 ft. square on plan, the "king" leg (that is, the leg supporting the crane) being larger than the "queen" legs. The three legs are placed from 20 to 30 ft. apart in the form of an equilateral or isosceles triangle. When two cranes are used, as is the case when important operations are to be conducted over the entire area of a circle, a four-legged square derrick tower is constructed, and a crane set upon a platform over each of two opposite legs. The ground upon which it is proposed to erect the towers must be well chosen for its solidity, or specially prepared to receive the towers. The foundation usually consists of a platform of 9-in. by 3-in. deals under each leg. The corner posts may be of three 9-in. by 3-in. deals bolted together, but those for the king leg may advantageously be larger. They are connected at every 8 or 10 ft. of their height by means of cross pieces or transoms from 7″ by 2″ to 9″ by 3″ in size, and each bay thus formed is filled in on all four sides with diagonal bracing of the same or slightly smaller timber. Up the centre of the king leg, from the bottom to the top, is carried an extra timber to take the weight of the crane. It may be a balk of whole timber, 12 or 14 in. square, or may consist of deals bolted together up to 16 in. square. This central member must be well braced and strutted from the four corners to resist any tendency to bending.

When the towers have reached the desired height the king leg is connected to each of the queen legs by a trussed girder; the two queen legs may be connected with each other either by a similar trussed girder or by a single timber which is supported by struts from the supporting legs to shorten the span and give rigidity. For the connecting girders a balk of timber reaching from king to



ELEVATION AND SECTION OF PLATFORM GANTRY SUPPORTING SCAFFOLD

queen legs is placed on each of the two topmost transoms, which may be from 4 to 8 ft. apart, the depth of the top bays often being modified to the required depth of the connecting beams. Upright struts are fixed at intervals of about 5 ft. between the two balks, which are also connected by long iron bolts and cross braces filled into each bay. The top balks project 6 or 10 ft. beyond the king leg and form the support for a working platform of deals. Struts are thrown out from the sides of the leg to support the ends of the balks. Upon the platform are laid two "sleepers" of balk timber extending from beneath the bed of the crane and passing over the centre of each queen leg. The "mast," a vertical member composed either of a single timber or two pieces strutted and braced, is erected upon the revolving crane bed, and the "jib," which is similar in construction to the mast, is attached to the base of the latter by a pivoted hinge. The jib is raised and lowered by a rope fixed near the end of the jib and running to the engine by way of a pulley wheel at the top of the mast. The rope or chain used for lifting the materials passes over a pulley at the end of the jib and thence to the winch over a pulley at the top of the mast. In the operation of lifting it is obvious that a great strain is put upon the mast and a considerable overturning force is exerted by the leverage of the weight lifted at the end of the jib. To counter-balance this, two timber "stays" or "guys" are taken from the mast head, one to the centre of each queen leg, and there secured. From these points two heavy chains are taken down the centre of each queen leg and anchored to the platform at their bases, which are each loaded with a quantity of bricks, stone or other heavy material equal in weight to at least twice any load to be lifted by the crane. A coupling screw link should be provided in the length of each anchor chain, so that it may be kept taut. The coupling screws should be placed in an accessible place near the ground, where they may easily be seen and tightened when necessary. The legs of the structure should be cross braced with each other to resist twisting tendencies due to wind pressure and swinging of the load, either by ties of steel bars with tightening screws, or, as is more usual, with diagonally placed scaffold-pole or squared-timber braces secured to the framework.

In the case of a three-towered gantry it is necessary to ballast only the two queen legs. Weighting of the king leg is unnecessary. With a square gantry having four legs, all should be weighted, and in calculating the ballast necessary for the crane towers the weight of the engine should be considered. Access to the platform is obtained by ladders fixed either inside or outside one of the queen legs. With the exception of the boards forming the working platform, which are usually spiked down, the timbers of a tower gantry should all be connected by screw bolts and nuts.

In steel-framed buildings the derrick tower is unnecessary, the revolving jib, base and engine being supported by the steel work and raised to succeeding heights as the work proceeds.

Swinging scaffolds or cradles, used in connection with painting, renovating and light repair work consists of light rigidly framed platforms suspended from cantilever supports. They are capable of being raised or lowered by the occupants of the cradle by means of block and fall tackle. A newer type of cradle is a modified form of the suspended scaffolding already described, the raising and lowering being done by machines attached direct to the metal frames which hold the platform and guard rails, instead of by "block and fall."

Scaffolding for Chimneys.—Tall chimney shafts may be erected by internal scaffolding only, or by a combination of external and internal staging. The latter method is often adopted when the lower part of the shaft is designed with ornamental brickwork, string courses, panels, etc., and it is important that this work should be carefully finished. An external scaffold is therefore carried up until plain work not more than 2 or $2\frac{1}{2}$ bricks thick is reached, when the remainder can be completed by "overhand"

work from an internal scaffold. The offsets made in the brickwork on the inside are used to support the timbering. For the repair of tall chimneys, light ladders are erected one above the other by a steeplejack and his assistants, each being lashed to the one below it and secured to the brickwork by dog-hooks driven in the joints. When the top of the chimney is reached balk timbers are raised by pulleys and laid across the top. From these are swung cradles from which the defective work is made good. If the work or weather demand a more stable scaffold, a light but strong framework of putlogs held together with iron bolts is fixed on each side of the shaft with iron holdfasts, and a platform of boards is laid upon them. For circular chimneys pieces of timber cut to a curve are clamped with iron to the putlogs to prevent them from bending when the bolts connecting the two frames are screwed up.

SCALA NUOVA (Turk. *Kush-Adasi*), also known as New Ephesus, a well-protected harbour on the west coast of Asia Minor and a kasa in the vilayet of Smyrna, opposite Samos. The site of the ancient Marathesium is close by. Pop. (1927) 14,715.

SCALE, in music, signifies any selected sequence of notes, or intervals, dividing up the octave. Thus it may consist entirely of semitones (chromatic scale); or entirely of whole tones (tonal scale); or partly of tones and partly of semitones, as in the ordinary diatonic scales, major and minor, of Western music. Our familiar major diatonic scale, represented by the white notes on the pianoforte beginning with C, consists of five tones and two semitones, with the semitones falling between the 3rd and 4th and the 7th and 8th notes.

SCALE INSECT, the name given to insects belonging to the family *Coccidae* of the order Hemiptera (*q.v.*). The females are inert wingless creatures usually with reduced legs and antennae, while the males are provided with a single pair of wings and have the legs and antennae well developed. Scale insects include a number of serious plant-pests, among the most injurious being the San José scale, the mussel scale, the fluted scale and certain of the mealy bugs. On the other hand, other species have a commercial value, notably the cochineal insect (*q.v.*), the lac insect (*q.v.*) and the so-called ground pearls (*q.v.*).

SCALES: *see* WEIGHING MACHINES.

SCALIGER, the Latinized name of the great Della Scala family. (*See* VERONA.) It has also been borne by two scholars of extraordinary eminence.

1. **Julius Caesar Scaliger** (1484–1558) was, according to his own account, a scion of the house of La Scala, born in 1484 at the castle of La Rocca on the Lago de Garda. At the age of twelve his kinsman the emperor Maximilian placed him among his pages. He remained for seventeen years in the service of the emperor, distinguishing himself as a soldier and as a captain. But he was unmindful neither of letters, nor of art, which he studied under Albrecht Dürer. In 1512 at the battle of Ravenna, where his father and elder brother were killed, he displayed prodigies of valour, and received the highest honours of chivalry, but no substantial reward, from his imperial cousin. After a brief employment by the duke of Ferrara, he entered (1514) as a student at the university of Bologna, where he remained until 1519. The next six years he passed in Piedmont, as a guest of the family of La Rovère, until a severe attack of rheumatic gout brought his military career to a close. Henceforth his life was wholly devoted to study. In 1525 he accompanied M. A. de la Rovère, bishop of Agen, to that city as his physician. Such is the outline of his own account of his early life. It was not until after his death that his son's enemies first alleged that he was the son of Benedetto Bordone, an illuminator or school-master of Verona; that he was educated at Padua, where he took the degree of M.D.; and that his story of his life and adventures before arriving at Agen was a tissue of fables. (*See* below *ad fin.*)

The remaining thirty-two years of his life were passed almost wholly at Agen, in the full light of contemporary history. At his death in 1558 he had the highest scientific and literary reputation of any man in Europe. A few days after his arrival at Agen he fell in love with Andiette de Roques Lobejac, and at forty-five he married Andiette, who was then sixteen. The marriage, of which there were fifteen children, was one of almost uninterrupted happiness. In 1531 he printed his first oration against Erasmus, in defence of Cicero and the Ciceronians. It is a piece of vigorous invective, displaying an astonishing command of Latin, and much brilliant rhetoric, but full of vulgar abuse, and completely missing the point of the *Ciceronianus* of Erasmus. The second is even more abusive, and less successful. The orations were followed by a prodigious quantity of Latin verse, which appeared in successive volumes in 1533, 1534, 1539, 1546 and 1547; of these, a friendly critic, Mark Pattison, is obliged to approve the judgment of Huet, who says, "par ses poésies brutes et informes Scaliger a déshonoré le Parnasse." A brief tract on comic metres (*De comicis dimensionibus*) and a work *De causis linguae Latinae*—the earliest Latin grammar on scientific principles and following a scientific method—were his only other purely literary works published in his lifetime. His *Poetice* appeared in 1561 after his death.

His scientific writings are all in the form of commentaries, and it was not until his seventieth year that (with the exception of a brief tract on the *De insomniis* of Hippocrates) he published any of them. In 1556 he printed his *Dialogue* on the *De plantis* attributed to Aristotle, and in 1557 his *Exercitationes* on the work of Jerome Cardan, *De subtilitate.* His other scientific works, *Commentaries* on Theophrastus' *De causis plantarum* and Aristotle's *History of Animals,* left in a more or less unfinished state, were not printed until after his death. His *Exercitationes* upon the *De subtilitate* of Cardan (1557) is the book by which Scaliger is best known as a philosopher. We are astonished at the encyclopaedic wealth of knowledge which the *Exercitationes* display, at the vigour of the author's style, at the accuracy of his observations, but are obliged to agree with G. Naudé that he has committed more faults than he has discovered in Cardan, and with Charles Nisard that his object seems to be to deny all that Cardan affirms and to affirm all that Cardan denies. Yet Leibniz and Sir William Hamilton recognized him as the best modern exponent of the physics and metaphysics of Aristotle. He died at Agen on Oct. 21, 1558.

2. **Joseph Justus Scaliger** (1540–1609), the greatest scholar of his day, was the tenth child of J. C. Scaliger. Born at Agen in 1540, he was sent when twelve years of age, with two younger brothers, to the college of Guienne at Bordeaux. An outbreak of the plague in 1555 caused the boys to return home, and for the next few years Joseph was his father's constant companion and amanuensis. Julius daily dictated to his son from eighty to a hundred lines of Latin verse, and sometimes more. Joseph was also required each day to write a Latin theme or declamation, though in other respects he seems to have been left to his own devices. He learned from his father to be an acute observer, never losing sight of the actual world, and aiming not so much at correcting texts as at laying the foundation of historical criticism.

After his father's death, he spent four years at the university of Paris, where he began the study of Greek under Turnebus. At the same time he taught himself. He read Homer in twenty-one days, and then went through all the other Greek poets, orators and historians, forming a grammar for himself as he went along. From Greek, at the suggestion of G. Postel, he proceeded to attack Hebrew, and then Arabic; of both he acquired a respectable knowledge, though not the critical mastery which he possessed in Latin and Greek. In 1563 Jean Dorat recommended him to Louis de Chastaigner, the young lord of La Roche Pozay, as a companion in his travels. A close friendship sprang up between the two young men, which remained unbroken till the death of Louis in 1595. The travellers first went to Rome. Here they found Marc Antoine Muretus, who had been a great favourite and occasional visitor of Julius Caesar at Agen. After visiting Italy, the travellers passed to England and Scotland. Scaliger formed an unfavourable opinion of the English. Their inhuman disposition, and inhospitable treatment of foreigners especially impressed him. He was also disappointed in finding few Greek manuscripts and few learned men. It was not until much later that he became intimate

with Richard Thompson and other Englishmen. In the course of his travels he had become a Protestant. In 1570 he proceeded to Valence to study jurisprudence under Cujas, the greatest living jurist. Here he remained three years.

The massacre of St. Bartholomew induced him to retire to Geneva, where he was appointed a professor in the academy. In 1574 he returned to France, and made his home for the next twenty years with Chastaigner. Of his life during this period we have interesting details and notices in the *Lettres françaises inédites de Joseph Scaliger,* edited by M. Tamizey de Larroque (Agen, 1881). During this period he published the books which showed that with him a new school of historical criticism had arisen. In his editions of the *Catalecta* (1575), of Festus (1575), of Catullus, Tibullus and Propertius (1577), he was the first to lay down and apply sound rules of criticism and emendation, and to change textual criticism from a series of haphazard guesses into a "rational procedure subject to fixed laws" (Pattison). But it was reserved for his edition of Manilius (1579), and his *De emendatione temporum* (1583), to revolutionize all the received ideas of ancient chronology—to show that ancient history is not confined to that of the Greeks and Romans, and that the historical narratives and fragments of Persia, Babylonia, Egypt and Palestine, and their several systems of chronology, must be critically compared, if any true and general conclusions are to be reached. It is this which places Scaliger immeasurably above any of his contemporaries. His commentary on Manilius is really a treatise on the astronomy of the ancients, and it forms an introduction to the *De emendatione temporum,* in which he examines by the light of modern and Copernican science the ancient system as applied to epochs, calendars and computations of time.

In the remaining twenty-four years of his life he at once corrected and enlarged the basis which he had laid in the *De emendatione.* With incredible patience, sometimes with a happy audacity of conjecture which itself is almost genius, he succeeded in reconstructing the lost *Chronicle* of Eusebius—one of the most precious remains of antiquity, and of the highest value for ancient chronology. This he printed in 1606 in his *Thesaurus temporum,* in which he collected, restored and arranged every chronological relic extant in Greek or Latin. When in 1590 Lipsius retired from Leyden, the university resolved to obtain Scaliger as his successor. He declined their offer. The next year it was renewed. It was made clear that lecturing would not be required of him, and he would be entirely his own master. About the middle of 1593 he started for Holland, where he passed the remaining thirteen years of his life. He was treated with the highest consideration. His rank as a prince of Verona was recognized. His literary dictatorship was unquestioned. From his throne at Leyden he ruled the learned world; a word from him could make or mar a rising reputation; and he was surrounded by young men eager to listen to and profit by his conversation. He encouraged Grotius when only a youth of sixteen to edit Capella; Daniel Heinsius, from being his favourite pupil, became his most intimate friend.

But Scaliger had made numerous enemies. He hated ignorance, but he hated still more half-learning, and most of all dishonesty in argument or in quotation. His pungent sarcasms were soon carried to the persons of whom they were uttered, and his pen was not less bitter than his tongue. Nor was he always right. He trusted much to his memory, which was occasionally treacherous. The Jesuits, who aspired to be the source of all scholarship and criticism, perceived that the writings and authority of Scaliger whose historical methods had discredited many of their claims were the most formidable barrier in their way. It was the day of conversions. Muretus in the latter part of his life professed the strictest orthodoxy; J. Lipsius had been reconciled to the Church of Rome; Casaubon was supposed to be wavering; but Scaliger was known to be hopeless, and as long as his supremacy was unquestioned the Protestants had the victory in learning.

After several scurrilous attacks by the Jesuit party, in 1607 a new and more successful attempt was made. Scaliger's weak point was his pride. In 1594, in an evil hour for his happiness and his reputation, he published his *Epistola de vetustate et splendore gentis Scaligerae et J. C. Scaligeri vita.* In 1607 Gaspar Scioppius, then in the service of the Jesuits, whom he afterwards so bitterly libelled, published his *Scaliger hypobolimaeus* ("the Supposititious Scaliger"). The main argument of the book is to show the falsity of Scaliger's pretensions to be of the family of La Scala, and of the narrative of his father's early life. To Scaliger the blow was crushing. Whatever the case as to Julius, Joseph had undoubtedly believed himself a prince of Verona, and in his *Epistola* had put forth with the most perfect good faith, and without inquiry, all that he had heard from his father. His reply, *Confutatio fabulae Burdonum,* was not a success. Scaliger undoubtedly exposes many pure lies and baseless calumnies; but he could not establish the family's supposed lineage. Scioppius was wont to boast that his book had killed Scaliger. It certainly embittered the remainder of his life. The *Confutatio* was his last work. Five months after it appeared, on Jan. 21, 1609, he died.

Of Joseph Scaliger the standard biography is that of Jacob Bernays (Berlin, 1855). *See* also his *Autobiography, with selections from his letters etc.,* trs. with introd. by G. W. W. Robinson (1927). *See* also J. E. Sandys, *History of Classical Scholarship,* ii. (1908), 199–204. For the life of J. C. Scaliger *see* the letters edited by his son, and his own writings, which are full of autobiographical matter.

SCALLOP. The popular name for a genus (*Pecten*) of edible marine molluscs belonging to the class Lamellibranchia. Nearly 300 living species of scallops are known and are found in all seas, from high latitudes to the tropics. The "scallop-shell of quiet" (Sir W. Raleigh) was worn as a badge by mediaeval pilgrims.

Pecten is placed in the second order (Filibranchia) of the Lamellibranchia along with *Arca* (the ark shell), *Mytilus* (mussels) and *Margaritana* (the pearl oyster). This group is characterized by the possession of gills in which the filaments are doubled on themselves, forming reflected lamellae (*see* LAMELLIBRANCHIA) and are joined together by ciliated disks, and by the highly developed byssus. In *Pecten* the foot is rudimentary and the animal is more or less sedentary, the byssus serving to fasten it down to the sea-bottom. The edges of the mantle are provided with highly developed eyes.

The common scallop of the British Isles (*Pecten opercularis*) is usually found in beds on a bottom composed of shell-débris with a little mud. Some of the largest beds are in the Firth of Forth, between Fleetwood and the Isle of Man, off Douglas and Weymouth. These beds are usually in water of 5–20 fathoms, though individual specimens are occasionally taken from much deeper water. Representatives of the sub-genus *Pseudoamussium* are found at greater depths (*e.g., P. neoceanicus* in 2,084 fathoms in the Pacific ocean).

See W. J. Dakin, "Pecten," *Mem. Liverpool Mar. Biol. Comm., xvii.* (1909); M. Küpfer *Die Sehorgane . . . der Pecten-arten.* (Zürich, 1916). (G. C. R.)

SCALP, in anatomy, the covering of the top of the head from the skin to the bone.

The skin of the scalp is thick and contains a large number of hair follicles. The arteries are remarkable for their tortuosity, which is an adaptation to so movable a part; for their anastomosing across the middle line with their fellows of the opposite side, an arrangement which is not usual in the body; and for the fact that, when cut, their ends are held open by the dense fibrous tissue in which they lie, so that bleeding is more free in the scalp than it is from arteries of the same size elsewhere in the body.

The veins do not follow the twists of the arteries but run a straight course; there is often a considerable distance between an artery and its companion vein. Accompanying the veins are the larger lymphatic vessels. From the forehead the lymphatics accompany the facial vein and usually reach their first gland in the submaxillary region, so that in the case of a poisoned wound of the forehead sympathetic swelling or suppuration would take place below the jaw. From the temple the lymphatics drain into a gland lying just in front of the ear, while those from the region behind the ear drain into glands lying close to the mastoid process. In the occipital region a small gland (or glands) is found about a third of the distance from the external occipital protuberance to the tip of the mastoid process (*see* SKULL).

The nerve supply of the scalp in its anterior part is from the fifth cranial or trigeminal nerve (*see* NERVES, CRANIAL); behind

the ear the scalp is supplied with sensation by the great auricular and the small occipital (*see* NERVES, SPINAL), while behind these, and reaching as far as the mid line posteriorly, the great occipital is distributed.

Beneath the skin and fibrous tissue lies the *epicranium,* formed by the two fleshy bellies of the occipito-frontalis muscle and the flattened tendon or aponeurosis between them. Of these two bellies the anterior (*frontalis*) is the larger, and, when it acts, throws the skin of the forehead into transverse puckers. The much smaller (*occipitalis* or posterior) belly usually merely fixes the aponeurosis for the frontalis to act, though some people have the power of alternately contracting the two muscles and so wagging their scalps backward and forward as monkeys do.

Deep to the epicranium is a layer of very lax areolar tissue constituting a lymph space and allowing great freedom of movement to the more superficial layers; it was this layer which was torn through when a Red Indian scalped his foe. So lax is the tissue here that any collection of blood or pus is quickly distributed throughout its whole area, and, owing to the absence of tension as well as of nerves, very little pain accompanies any such effusion.

The deepest layer of the scalp is the *pericranium* or the external periosteum of the skull bones. This, until the sutures of the skull close in middle life, is continuous with the dura mater which forms the internal periosteum, and for this reason any subpericranial effusion is localized to the area of the skull bone over which it happens to lie. Moreover, any suppurative process may extend through the sutures to the meninges of the brain.

(F. G. P.)

SCALPING. The common term for the practice of removing, as a trophy, a portion of the skin, "shell" or "sheath," with hair attached, from an enemy's head. The custom was not unknown to the Old World, as it was mentioned by Herodotus as practised by the Scythians. It has been regarded, however, as a prevalent one among the American Indians, yet, contrary to the general belief, not all the tribes practised it by any means. Extended researches by Friederici indicate that in North America it was confined originally to a limited area in eastern United States and the lower St. Lawrence region, about equivalent to the territory held by the Iroquois and Muskhogean tribes and their neighbours. The custom was absent from New England and much of the Atlantic coast region, and was unknown until comparatively recent times throughout the interior and the Plains area; it was not practised on the Pacific coast, in the Canadian North-west nor in the Arctic region, nor anywhere south of the United States with the exception of an area in the Gran Chaco country of South America. Throughout most of America the early trophy was the head itself. The spread of the scalping practice over the greater part of central and western United States was stimulated by scalp-bounties offered by the colonial and more recent governments, the scalp itself being superior to the head as a trophy by reason of its lighter weight and greater adaptability to display and ornamentation.

The operation of scalping was painful, but by no means fatal. The impression that it was fatal probably arose from the fact that the scalp was usually taken from the head of a slain enemy as a trophy of his death, but among the Plains tribes the attacking warrior frequently strove to overpower his enemy and scalp him alive, to inflict greater agony before killing him; and frequently also a captured enemy was scalped alive and permitted to return to his people as a direct defiance and as an incitement to retaliation. The part taken was usually a small circular patch of skin at the root of the scalp-lock just back of the crown. The scalp-lock itself was the small hair braid which hung from the back of the head, as distinguished from the larger side braids. When opportunity offered, the whole top skin of the head, with the hair attached, was removed, to be divided later into smaller locks for decorating the clothing of warriors. The operation was performed by making a quick knife stroke around the head of a fallen enemy, followed by a strong tug of the scalp-lock. The scalper was not necessarily he who had killed the victim; nor was the number of scalps, but rather the number of *coups* (*i.e.,* "strokes" or acts of bravery in battle), the measure of the warrior's prowess. The fresh scalp was sometimes offered with prayer as a sacrifice to the sun, the water or some other divinity. When preserved for a time, as was most usual, the scalp was cleaned of the loose flesh and then stretched by means of sinew cords around the circumference within a hoop about six inches in diameter, tied at the end of a rod. When dry the skin side was painted either entirely red, or one half red and the other half black, and the hair was usually carefully braided and embellished with various ornaments. It was carried thus by the women in the triumphal scalp or victory dance on the return of a successful war-party to the home camp, and then, having served its first purpose, was retained as a bridle pendant by the warrior, deposited with the tribal "medicine," or thrown away in some secluded spot. This may be regarded as the typical treatment; but scalp customs varied from tribe to tribe, as likewise did the associated beliefs and rites. The custom is involved with that of decapitation, the severing of parts of the body, such as fingers, etc., as war trophies, and the shrinking of the heads of enemies as among the Jivaro Indians of Ecuador.

See G. Friederici, *Skalpieren und ähnliche Kriegsgebräuche in Amerika* (Brunswick, 1906), with extended bibliography, and summarized in *Ann. Rep. Smithsonian Inst. for 1906* (Washington, 1907).

(F. W. H.)

SCAMMONY, a plant, *Convolvulus Scammonia,* native to the countries of the eastern Mediterranean basin; it grows in bushy waste places, from Syria in the south to the Crimea in the north, its range extending westward to the Greek islands, but not to northern Africa or Italy. It is a twining perennial, bearing flowers like those of the field or corn bindweed, *Convolvulus arvensis,* and having irregularly arrow-shaped leaves and a thick fleshy root. The dried juice, "virgin scammony," obtained by incision of the living root, has been used in medicine as *scammonium,* but the variable quality of the drug has led to the employment of *scammoniae resina,* which is obtained from the dried root by digestion with alcohol. The active principle is the glucoside scammonin or jalapin, $C_{34}H_{56}O_{16}$; it is a powerful purgative.

SCAMOZZI IONIC ORDER, in architecture, a type of Ionic order in which the capital has all four faces identical, with the volutes meeting at an angle in the corners, and at the centre rolling down into the top of the echinus, instead of being connected by a band above the echinus. There is usually a rosette or flower in the centre of each face of the capital, on top of the echinus, and the abacus or top slab is concave-sided as in the Corinthian order. It receives its name from the late Renaissance architect Vincenzo Scamozzi (1552–1616), who was once thought to have invented it, although there are Roman precedents, such as the temple of Saturn at Rome (early 4th century). *See* ORDER.

SCANDAL, disgrace, discredit, shame, caused by the report or knowledge of wrongdoing, hence defamation or gossip, especially malicious or idle; or such action as causes public offence or disrepute. A particular form of defamation was *scandalum magnatum,* "slander of great men," words, that is, spoken defaming a peer spiritual or temporal, judge or dignitary of the realm. Action lay for such defamation under the statutes of 3 Edw. I. c. 34, 2 Rich. II. c. 5, and 12 Rich. II. c. 11 whereby damages could be recovered, even in cases where no action would lie, if the defamation were of an ordinary subject, and that without proof of special damage. These statutes, though long obsolete, were only abolished in 1887 (Statute Law Revision Act).

SCANDINAVIAN CIVILIZATION. At the close of the Ice Age climatic conditions at last allowed man to enter Scandinavia; but authorities differ as to when this occurred, suggestions varying from 10,000 B.C. to 6,000 B.C.

Epipalaeolithic Period.—The earliest civilizations belong to the so-called Epipalaeolithic Period, of which two stages are at present recognised in Denmark, called after their type-stations the Maglemose and Ertebolle Periods. The former is that of a race of fishermen who lived on the shores of the Baltic while it was still a great fresh-water lake (called by geologists Ancylus lake); at Maglemose were found many tools of bone, horn and stone: the most typical being the barbed harpoon of bone or

horn and a chipped flint axe known as the tranchet. Pottery was not found. In the following period (Ertebolle) a rise in sea-level had allowed the sea to flow into the Baltic (this is called by geologists the Littorina sea). The typical remains of this age are usually found in vast rubbish-heaps or kitchen-middens (kjøkkenmøddinger). Bone and horn tools and other objects, *e.g.*, combs were still used, but flint was now the most important material. Pottery had come into use, the commonest form being a wide-mouthed bulging jar with pointed base. It is probable that in Norway and Sweden similar settlements existed, at present less fully known; for instance, remains at Nøstvet in Norway and at Limhamn in Sweden resemble and may be contemporary with those at Ertebolle. With the exception of the dog, domestic animals were unknown at this period, and agriculture was not practised.

Neolithic Period.—In the remoter districts of Norway and Sweden the epipalaeolithic people retained their primitive mode of life for a long time, untouched by the more advanced, neolithic civilizations developing to the south of them.

Our knowledge of these neolithic civilizations is almost entirely gathered from a study of the burial customs of the period. Such dwellings as are known are simple circular mud huts, containing few remains but animal bones, etc. All the more important graves of this period in Scandinavia are megalithic structures, a chronological sequence of three types being recognised (corresponding to Montelius' Periods II., III. and IV.). The earliest form of tomb was the *Dolmen* (*q.v.*), a small chamber enclosed by three or more rude upright stones, roofed by a single great stone slab, and often still partially covered by a mound. These graves, which usually contained several unburnt bodies, are not very richly furnished, but are characterized by the thin-butted axe (so-called celt) of flint, usually ground and polished, and by pottery, mostly ornamented flasks and vases. From these came the *Passage Grave* (*Chamber-Tomb*), a more elaborate structure in which a large megalithic chamber was approached by a passage walled and roofed with stone slabs. Such tombs are often of great size; a typical example figured by Du Chaillu, at Axvalla Heath, near Lake Venern, Vestergotland, Sweden, has a chamber 32×9 ft. and a passage 20 ft. long. These communal tombs sometimes contained as many as 100 skeletons, unburnt, and numerous associated objects. Some of the most typical are the thick-butted axe of flint, sometimes ground and polished; the perforated stone axe; transverse arrowheads and arrowheads with triangular section; oval, thick-butted daggers of chipped flint; amber beads; and pottery, usually angular or round bottomed bowls. The Passage Grave then degenerated into the *Long Stone Cist*. These graves also contained numerous skeletons, but are scantily furnished, the typical objects being a lunate knife of chipped flint and a beautiful, handled dagger, perhaps the finest achievement of any flint-workers. The pottery was poor and undecorated.

The civilization of the megalith-builders indicates a highly organized society of traders and farmers. Remains of domestic animals (horse, sheep, swine, cattle and dog) and traces of the cultivation of grain (barley, wheat and flax) are found round their huts; animal bones are also found in the mounds covering the tombs. Trade is proved by the occurrence of objects of Scandinavian origin in Britain (*e.g.*, perforated axes and thick-butted dagger-blades of Scandinavian workmanship in graves of the Beaker Period) and in central Europe (*e.g.*, necklaces of Baltic amber in Aunjetitz graves) and vice versa. The graves are most thickly distributed round the coastal districts of Denmark and Sweden, only in the latest (Long Stone Cist) period spreading to Norway and inner Sweden.

Contemporary with the megalithic burials a custom existed (chiefly in Jutland, S. Sweden and some of the Danish Islands) of burying each person in a small separate grave; several of these being covered by one barrow and found at different levels in it, either sunk in the earth, on the ground level or actually in the mound (bottom graves, ground graves and upper graves). These graves have pottery beakers and elaborate perforated stone axes, usually called battle axes. Axes and pottery of this type are widely distributed in Europe and these graves conceivably represent the entrance into Scandinavia of another race, who ultimately merged with the megalith-builders, since in the Long Stone Cist period there is little distinction between the furniture of the megalithic and of the separate graves.

Duration of Neolithic and Bronze Periods.—Prof. Gordon Childe, surveying the various estimates of the duration of the neolithic period in Scandinavia, suggests the following dates: Dolmen Period (Montelius Period II.), 2500–2200 B.C.; Passage-grave Period (Montelius Period III.), 2200–1650 B.C.; Long Stone Cist Period (Montelius Period IV.), 1650–1500 B.C. The last period belongs technically to the Bronze Age, since small objects of metal are occasionally found (copper and bronze pins and gold ear-rings).

Owing to the necessity of importing the metal the Bronze Age began late in Scandinavia; it probably lasted almost until the beginning of the Christian era. Here again much information is derived from burials, but hoards of objects are also of great importance. The dwelling-sites are imperfectly known.

Montelius, in his chronological classification of the Scandinavian Bronze Age, distinguishes two main periods, an Earlier and a Later, each having three subdivisions; but for a general survey the division into two periods is sufficient; the first probably ending about 1000 B.C., the second lasting till a few centuries before the Christian Era.

Earlier Bronze Period.—The sequence of metal types was much the same as in the rest of northern Europe. (*See* British Museum Guide, *Bronze Age*, Evolution of the Axe, Spear and Sword.) Early in the period the forms were simple, the flat and flanged axe and small knife being the commonest tools; at this time stone was probably in much commoner use than metal. But before long the innate craftsmanship of the Scandinavian asserted itself, and bronze weapons and ornaments were evolved unequalled in northern Europe for utility and elegance. That these were not importations is proved by the discovery of moulds in which such objects were cast and by the difference in technique between these objects and those of other countries.

The typical weapons were: Axes, of various forms, as, the palstave, the socketed and perforated axe; spears with riveted sockets; daggers and swords. The rapier or thrusting type of sword common throughout Europe in the middle Bronze Age was little used, being early replaced before A.D. 1000 by the heavier broad sword (leaf-shaped type), which came into use at an earlier date than in, *e.g.*, Britain. Some archaeologists hold that this type which was widely distributed through Europe, was actually evolved in Scandinavia by smiths who were, through the amber trade with Southern Europe, acquainted with the Italian bronze-handled dagger; others believe that Hungary was the place of origin. Some of the Scandinavian swords have a cast bronze hilt, others a hilt of wood or horn, etc., riveted in slabs on to a flanged bronze tang. The only defensive weapon which has survived is the circular bronze buckler, but such authorities as hold that the famous rock-carvings are of Bronze Age date deduce from these that horned helmets were worn. If the later phase of the Scandinavian Bronze Age was contemporary with the British Early Iron Age, these may well have taken the form of the bronze helmet in the British Museum found in the River Thames.

Personal ornaments were now for the first time abundant. These are usually of bronze but sometimes of gold. They include: Finger-rings, bracelets and torcs of various forms (coiled wire, cast or hammered); tutuli, *i.e.*, conical bosses apparently attached to the belt; pins, frequently disc-headed or with hanging ornaments; and brooches.

Both weapons and ornaments were commonly decorated at this time with incised designs, sometimes of chevrons, etc., but most often of spirals. This spiral ornament is often so marvellously regular as to suggest that some mechanical means was employed.

The distribution of finds suggests that there was at this time a considerable population throughout Southern Scandinavia.

The dead were at this period disposed unburnt in coffins, sometimes in the form of small stone cists but sometimes of wood, roughly hewn from a single tree-trunk. Some of these tree-trunk

burials are of great interest as giving examples of the clothing worn. An oak coffin in a barrow (called Treenhøi) at Havdrup in Ribe, Denmark, contained a male skeleton with all his clothes preserved. These were: a high round cap, a wide mantle, a kind of kilt and two small fragments of leg-coverings, all of woven wool, and the remains of leather shoes. The inside of the mantle and a woollen belt which confined the kilt were fringed. A woollen shawl was rolled up to make a pillow. At the left side of the body was a sword in a sheath, and at the foot a wooden box containing a smaller box in which were another cap, a horn comb and a bronze razor. The whole contents of the grave was wrapped in an untanned hide. A complementary find at Borum-Eshoi, near Arhus, also in an oak coffin, produced a woman's dress, consisting of a long under-robe and a sleeved bodice both of woven wool, a cap of netted worsted, a tasseled belt woven of wool and cowhair, and a large mantle of woven wool and cowhair. Another cap was found in the grave, which also contained a bronze brooch, a horn comb, a finger-ring, two bracelets, a torc, three tutli and a horn-handled bronze dagger.

Later Bronze Period.—In this period cremation became general. The burnt bones were at first put in small stone cists, a number being often found under one mound; later the remains were placed in pottery urns, often still placed in cists; sometimes they were simply laid in the ground and covered with a stone. The pottery was usually in the form of plain jars and bowls, sometimes handled. Tomb furniture, especially weapons, became scantier. There is no visible break with the earlier period in the type of weapons; but gradually a new type of decoration was employed, and new kinds of household objects, ornaments, etc., were introduced. These include ornamented bronze vessels of various forms, often for hanging; a new kind of knife (so-called razor); and many personal ornaments. These are decorated with repoussé as well as with incised ornament, sometimes in the form of degenerate spirals, sometimes circles, and frequently wavy ribbon patterns and curves suggesting roughly drawn boats with bird's head terminals. Many of these were imported, being of Italian design; others are local imitations. The ornament is also foreign, being typical of the Hallstatt (earliest Iron Age) civilization of central Europe. The sword pommels are also of Hallstatt types. This period, therefore, although definitely part of the Bronze Age, was strongly influenced by the Iron Age of central and southern Europe, being contemporary with the Hallstatt Period.

At the close of this period a few iron objects of La Tène type, such as swords and brooches, occur in cremation graves otherwise indistinguishable from those of the Bronze Age, and represent the beginning of the use of iron in Scandinavia, probably dating in the first century or two B.C.

Rock Carvings.—On rocks in some districts of Sweden and Norway numerous crude carvings exist, representing scenes of fighting, husbandry, seafaring, etc. If, as most people believe, these belong to the Bronze Age, they throw a flood of light on the daily life of the time. But their dates are as yet unproved.

BOG FINDS

Although Scandinavia was always outside the Roman Empire the influence of that power was strongly shown in contemporary Scandinavian civilization. Very many objects of Roman manufacture were imported, often of good quality, showing that Scandinavia was prosperous and traded freely with the continent. Large numbers of Roman coins have been found, especially in the island of Gotland. Native art shows strong Roman influence.

At this time iron was of course in general use. Much information about the period is derived from hoards found in peat-bogs at Thorsbjerg, Vimose, Nydam and other sites in Jutland and Schleswig. These are supposed to be votive offerings following a battle. The weapons are remarkably fine, and include swords, single and double-edged, and damascened (the double-edged types having hilts resembling the Roman form); spears of various patterns, ornamented and sometimes inlaid on the blade; axes, socketed and perforated; chain-mail; helmets, one of silver; and shield-bosses. Tools of all kinds were found; also personal ornaments. Perhaps the most important find was that of a clinker-built boat 75 ft. long, at Nydam, built of oak and probably dating in the III. century A.D.; another of red pine was found.

Migration Period.—After the collapse of the Roman Empire in the west in the V. century A.D. Scandinavian civilization developed gradually in harmony with the Teutonic civilizations to the south of it and in England. Again little is known of the houses of the period; the majority seem to have been four-sided huts. Burials are the chief source of information. Both inhumation and cremation were practised; the tomb furniture was rich, especially in personal ornaments and square-headed and cruciform brooches. These and other ornaments were decorated in a new style common to Scandinavia and the rest of Teutonic Europe at this period, consisting partly of geometric designs, spirals, stars, etc., and partly based on conventionalized and disintegrating animal forms, executed in a variety of techniques. The materials were sometimes bronze, occasionally silver and sometimes gold; the latter was most freely used in Sweden. In Gotland inlaid garnet ornament was popular, a technique which unlike the animal ornament occurs only sporadically in northern Europe. An ornament peculiar to Scandinavia was the bracteate, a disc-shaped gold pendant derived from barbarous copies of late Roman and Byzantine coins. The commonest weapons were the spear and shield. Swords, single and double edged, were not uncommon. Glass and wooden vessels as well as pottery are found.

Viking Period.—In the VIII. century the northern peoples, who had hitherto when restive contented themselves with local warfare and commercial ventures abroad, began to engage in piratical forays overseas. These were at first mere plundering raids resembling those of the Anglo-Saxons on the frontiers of the moribund Roman Empire in the III. and IV. centuries; but (like these) led ultimately to wide-spread colonization in England, northern France, Ireland, Scotland, the Faroes, the Orkneys, Shetland, Sicily and Russia; and to the discovery of Iceland, Greenland and America and the colonization of the two former. Their raids were pushed into almost every corner of Europe and they visited Asia Minor and North Africa.

We are fortunate in being able to examine in detail typical vessels in which they adventured, owing to their custom of burying the dead in their ships, under barrows; and it is not an exaggeration to say that all the finer developments of the sailing-ship were founded on their lines. A typical small war-vessel of the period was found at Gokstad, near Sandefjord in south Norway, and what might be described as a royal pleasure-vessel at Oseberg. Both contained a complete outfit; in the first were the chief's arms, horses, etc.; in the second the queen's bed, sledges, vessels, ornaments, etc. Lest anyone should doubt the seaworthiness of these vessels an exact model of the Gokstad ship was built and sailed across the Atlantic in 1893 and afterwards shown at the Chicago exhibition; it proved an able sea-boat.

In the Sagas, which provide a fund of information about life in those days (*see* SAGA) the affection of the Vikings for their ships is clearly shown, and they are often referred to by poetical names, such as Sea-skates, Elk of the Fjords, Horse of the Gull's Track, Raven of the Sea, etc.

Apart from warfare, farming was the chief occupation of the Vikings, and for this purpose slaves (thralls) were largely employed; but even kings took an active part in this pursuit. Ale-drinking, story-telling and games occupied the winter, every household having its winter store of dried meat and fish and home-brewed ale. Hospitality was practised on the grandest scale. The vivid description in the sagas of life in the halls of the northmen has been verified by excavation, "Fire-Halls" being found resembling mediaeval tithe-barns.

Typical antiquities of the period are found wherever the Vikings settled. Since paganism prevailed until about A.D. 1000 in Norway and Iceland and even later in Sweden, tomb furniture was abundant in the earlier period. There was a great variety of burial customs; both inhumation and cremation were practised and the latter was not confined to the less elaborate tombs; it gradually died out, however, before the spread of Christianity. Men

were often buried with a complete outfit of weapons, horse, dogs, harness, etc.; and not infrequently were buried in their boats; women had personal ornaments, household gear, etc. Boat burials were rare in Denmark, and in place of the big ship burials important persons were buried in wooden tomb chambers under mounds.

As might be expected, continual fighting led to the development of far more efficient weapons than had hitherto been known. Although the spear, used for both throwing and thrusting, still played an important part, the axe now reached an importance not seen since the Bronze Age; and the beautiful horned forms evolved (*cf.* Bayeux Tapestry) attest the skill of the Viking blacksmith. Splendid swords are found in the graves, frequently inlaid with gold and silver. Defensive weapons are represented by the shield, helmet and coat of ring-mail (*byrnja*). From the numerous descriptions in the Sagas we gather that a Viking's weapons were his most esteemed possessions; like the ships they are frequently described in such terms as:—for the sword, the Ice of Battle, the Dog of the Helmet, the Viper of the Host, etc.; for the spear, the Snake of the Attack, the Shooting Serpent, etc.; for the axe, the Witch of the Shield, the Wolf of the Wound; for arrows, the Bird of the Sling, the Twigs of the Corpse, etc.; for shields, the Burgh of the Swords, the Moon of Battle; for the *byrnja,* Gray clothes of Odin, the Woof of the Spear, etc. They also had personal names, as Magnus Barefoot's sword Legbiter, Skarphedin's axe, Ogress of War; and Harald Hardrada's byrnja, Emma.

Most objects are covered with decoration, the style of which at first derived from that of the end of the Migration Period (Vendel Style, conventionalized animal forms; but as a result of foreign intercourse, especially with Ireland and the Carolingian Empire, a new style of a hybrid character developed towards the close of the 8th century. Very good examples of this "Gripping beast" style are to be seen in the Oseberg Find. In the 10th century the Gripping beast style was overshadowed by the Jellinge style, in which animal forms are treated more naturalistically. This style, which in some ways resembles the Vendel style, is usually regarded as the outcome of Irish, English and Carolingian influence. The Jellinge style gave place for a time during the early 11th century to that of Ringerike, characterized by pure interlacing and conventionalized foliage, the animal motive being negligible; but later the interlaced animal of the Jellinge style reappeared in the Urnes style, at the close of which native Scandinavian art was overwhelmed by the bastard Romanesque of the Christian era.

Bibliography.—For the earlier period (Stone Age to end of Iron age) see *Reallexikon der Vorgeschichte* (ed. by Max Ebert, Berlin 1927), vol. ix., article entitled "Nordischer Kreis," with exhaustive bibliographies. Many of the works mentioned there (*e.g.,* Montelius, *Kulturgeschichte Schwedens* (Leipzig, 1906), Rygh, *Norske Oldsager* (Christiania, 1885), Gustafson, *Norges Oldtid* (Christiania, 1906), etc., deal also with the later period (Iron Age to end of Viking period). (T. C. L.; M. O'R.)

SCANDINAVIAN LANGUAGES. Closely allied languages are and have been spoken by the Teutonic population in Scandinavia, and by the inhabitants of the countries that have been wholly or partially peopled from it, in Sweden, except where Finnish and Lappish prevail; in southern Russia (government of Kerson), a village colonized from Dagö; Norway, except where peopled by Finns and Lapps; Denmark, with the Faeroes, Iceland and Greenland, and the northern half of Slesvig Nord. Scandinavian dialects were also spoken for varying periods in the following places: Norwegian in certain parts of Ireland (A.D. 800–1250) and northern Scotland, in the Isle of Man (800–1450), the Hebrides (800–1400), the Shetland Islands (800–1800), and the Orkneys (800–1800), Danish in the whole of Slesvig Nord, in the north-eastern part of England (the Danelagh, *q.v.,* 875–1175), and in Normandy (900–1100 or a little longer); Swedish in Russia (862–1300 or a little longer); Icelandic in Greenland (985–*c.* 1450).

The Teutonic population existed in Scandinavia before the Christian era, and it is only from the beginning of that era that we get any information concerning the language of the old Scandinavians, which by that time had spread over Denmark and great parts of southern and middle Sweden and of Norway, and had reached Finland (at least Nyland) and Estonia. The language appears to have been fairly homogeneous throughout the whole territory, and as the mother of the younger Scandinavian tongues has been named the primitive Scandinavian (*urnordisk*) language. The words borrowed during the first centuries of the Christian era by the Lapps from the inhabitants of central Sweden and Norway, and by the Finns from their neighbours in Finland and Estonia, and partly from their Gothic neighbours in Russia and the Baltic provinces, and preserved in Finnish and Lappish down to our own days, denoted chiefly utensils belonging to a fairly advanced stage of culture and amount to several hundreds, with a phonetic form of a very primitive stamp. These words and those mentioned by contemporary Roman and Greek authors are the oldest existing traces of any Teutonic language, but throw little light on the nature of the original northern tongue. The primitive northern runic inscriptions, the oldest upon the utensils found at Vi in Slesvig Nord and Thorsbjerg in Denmark, dating back to about A.D. 250–300, together with the ms. fragments of Ulfilas' Gothic translation of the Bible, about 200 years later in date, constitute the oldest genuine monuments of any Teutonic tongue.

Although very brief, and not yet thoroughly interpreted, these primitive Scandinavian inscriptions enable us to determine with some certainty the relation which the language in which they are written bears to other languages. Thus it belongs to the Teutonic family of the Indo-European stock of languages, of which it constitutes an independent and individual branch. Its nearest relation being the Gothic, these two branches were formerly sometimes taken together under the general denomination *Eastern Teutonic,* as opposed to the other Teutonic idioms (German, English, Dutch, etc.), then called *Western Teutonic.*

Before the beginning of the so-called Viking period (since about A.D. 800) the primitive Scandinavian language had undergone a considerable transformation, and at this epoch the primitive Scandinavian language must be considered as no longer existing. The centuries A.D. 700–1000 form a period of transition as regards the language as well as the alphabet which it employed. The language of inscriptions dating from about A.D. 800 not only differs widely from the original Scandinavian, but also exhibits dialectical peculiarities suggesting the existence of a Danish-Swedish language as opposed to Norwegian. These differences are unimportant and the Scandinavians still considered their language as one and the same throughout Scandinavia, and named it *Dǫnsk tunga,* Danish tongue. But when Iceland was colonized (*c.* 900), chiefly from western Norway, a separate (western) Norwegian dialect gradually sprang up, at first differing slightly from the mother-tongue. At the definitive introduction of Christianity (about A.D. 1000), the language had been differentiated in runic inscriptions and in the literature which was then arising, into four different dialects, and Swedish and Danish (*eastern Scandinavian*) and Icelandic and Norwegian (*western Scandinavian,* or northern tongue) are very nearly related to each other. The most

important differences between the two branches, as seen in the oldest preserved documents, are (1) in E. Scand. for fewer cases of "Umlaut," (2) E. Scand. "Brechung" of *y* into *iu* (or *io*) before *ng(w)*, *nk(w)*; (3) in E. Scand. *mp, nk, nt* are in many cases not assimilated into *pp, kk, tt;* (4) in E. Scand. the dative of the definite plural ends in *-umin* instead of W. Scand. *-onom*; (5) in E. Scand. the simplification of the verbal inflectional endings is much farther advanced, and the passive ends in *-s(s)* for *-sk*. In several of these points, and indeed generally speaking, the western Scandinavian languages have preserved the more primitive forms, which also are found in the oldest eastern Scandinavian runic inscriptions, dating from a period before the beginning of the literature, as well as in many modern eastern Scandinavian dialects. Leaving out of account the Icelandic dialects and those of the Faeroes, each of which constitutes a separate group, the remainder may be thus classified:—

1. **West Norwegian Dialects**—spoken on the western coast of Norway between Langesund and Molde.
2. **North Scandinavian**—the remaining Norwegian and the Swedish dialects of Uppland, Västmanland, Dalarna, Norrland, Finland, and Russia.
3. The dialects on the island of Gotland.
4. **Middle Swedish**—spoken in the rest of Sweden, except the southernmost parts (No. 5).
5. **South Scandinavian**—spoken in the greater part of Småland and Halland, the whole of Skåne, Blekinge, and Denmark, and the Danish-speaking part of Slesvig Nord. This group is distinctly divided into three smaller groups—the dialects of southern Sweden (with the island of Bornholm), of the Danish islands, and of Jutland (and Slesvig Nord).

SCANDIUM, one of the rare-earth metals. The discovery of its oxide, *scandia*, by L. F. Nilson in 1879 was of the greatest scientific interest, because this oxide and the other compounds of scandium have properties corresponding with those predicted by D. Mendeleyev in 1869 for the derivatives of a hypothetical element, ekaboron, which was then needed to fill a gap in the periodic classification of the chemical elements. (*See* PERIODIC LAW.) The metal itself, symbol Sc, atomic number 21, atomic weight 45·1, has not been isolated, but its oxide is found combined in the following minerals: thortveitite (Sc_2O_3, 42%) from Saetersdalen, Norway, wiikite from Impilako, Finland (Sc_2O_3, 1·2%), ytherbite (gadolinite) and orthite, and in many tin ores and wolframites. Spectroscopic observations show that scandium is relatively abundant in the sun and stars. Scandia forms many salts with inorganic and organic acids which are generally colourless. Scandium acetylacetone, $Sc[(CH_3{\cdot}CO)_2CH]_3$, crystallises from organic solvents in colourless, prismatic needles, melts at 188° C and may be distilled unchanged under 8–10 mm. pressure.

(G. T. M.)

SCAPA FLOW, an expanse of sea, in the south of the Orkneys, bounded by Pomona on the north, Burray and South Ronaldshay on the east and south-east, and Hoy on the west and south-west. The area contains seven small islands and is about 15 m. in length from north to south, and about 8 m. in mean breadth. There are two chief exits—one, 7 m. in length and 2 m. in mean breadth, into the Atlantic Ocean by Hoy Sound, and the other, 3½ m. in length by 2 m. in mean breadth, into the North Sea by Holm Sound.

Admiral Jellicoe chose Scapa Flow in preference to the Cromarty Firth as the chief naval base of the British fleet in the World War, but in Aug. 1914 everything had to be improvised, guns being landed from the ships to strengthen the defences. Scapa Flow thus gradually assumed the aspect of a great naval station. The German ships surrendered in Nov. 1918 were interned in Scapa Flow, where on June 21, 1919 all the battleships and battle cruisers, with the exception of the battleship "Baden" and five light cruisers, were scuttled by their German crews. Three light cruisers and some smaller vessels were beached.

Naval Aspects.—Scapa Flow now has an historic interest which would never have been attached to it save for the World War. As the main base of the Grand Fleet throughout the earlier period of the war it was a strategic position of great importance. Long before August 1914 it had been used by the ships of the Home or Channel fleets on periodical visits to northern waters, because its roomy and well-sheltered waters provided at one and the same time a good anchorage and an excellent practice ground. In the Admiralty war plans it was the intention that the main fleet should work from this base and control the North Sea, while a smaller fleet based on Portland would watch the English Channel. The Grand Fleet, as it was afterwards called, moved to Scapa Flow during the latter days of July 1914 and it was therefore at its war station at the outbreak of hostilities, but at that time this anchorage was far from being secure against attack by submarines, and in the early days numerous scares arose in the fleet that enemy submarines had actually penetrated into the harbour. In point of fact no German submarine ever did achieve the dangerous passage into the Flow. Apart from the defences which were eventually established, the very strong currents across the entrance made navigation under water especially risky. One enemy submarine was destroyed in the outer approaches in November 1914, and four years later, after the mutiny in the German fleet, one of their submarines manned entirely by officers, perished in a last despairing effort to achieve success.

All channels to Scapa Flow, except the Hoxa and Hoy entrances, were fairly effectively blocked by sinking old ships in them. A submarine obstruction was placed in the Hoy entrance, while the fleet used the Hoxa sound, which was also protected and closely patrolled. In addition to these obstructions, the gun defences were materially increased, while facilities for maintenance were improved by the addition of a small floating dock for destroyers and the provision of a number of repair and supply ships.

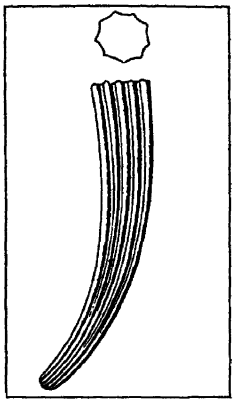
Although Scapa Flow had many advantages, the fleet felt the want of a fully equipped dockyard nearer than those in the south of England, and this in due course was met by sending a large floating dock to Invergordon in the Cromarty Firth, while the work on the newly-started dockyard at Rosyth on the Firth of Forth was pressed forward as rapidly as possible. With the completion of the outer defences of the latter, the greater part of the Grand Fleet was eventually moved south to join the battle cruisers which had been based on the southern port since December 1914.

The Flow was, nevertheless, to witness one final dramatic scene, when on June 21, 1919, the most important units of what had been the German High Sea Fleet, interned in its waters, were scuttled and abandoned by their crews. The situation which made this possible has often been misunderstood and attributed to some laxity on the part of the British ships on guard. In fact it was impossible for the latter to prevent what was done. In spite of the protests of Britain's naval representatives, her allies would not agree to her definitely taking over the German vessels; they were therefore interned and not surrendered, which meant that they retained the officers and crews which had navigated them across the North Sea, and were only under such distant observation that it was impossible to detect the preconcerted and simultaneous opening of under-water valves which led to their sinking. The Germans were evidently intent on avoiding the humiliation of seeing their best ships under the flag of a foreign navy, but it must have been a poor consolation that their last resting-place should have been in the very waters from which the fleet which had over-awed them throughout the war was wont to set forth. They were, moreover, compelled to pay dearly for their breach of faith by having to surrender other tonnage. By 1928 a number of the ships had been raised by a British firm and broken

up to be sold as scrap iron, and the work was still continuing.

Scapa Flow is visited from time to time by the British Atlantic Fleet, but with the exception of the salvage work it has largely sunk back to the peaceful conditions prevalent there before the World War. (E. A.)

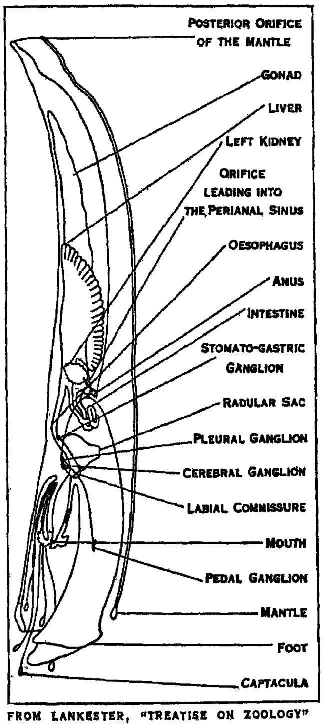
SCAPHOPODA. A group of marine invertebrate animals popularly called elephant's tusk shells and constituting a class of the Mollusca (*q.v.*). They are represented by 12 genera (of which *Dentalium* is the most familiar), and over 300 species, and are the smallest molluscan class. Their structure is quite distinct from that of other molluscs. They are bilaterally symmetrical, elongate animals in which the right and left edges of the mantle are joined in the mid-ventral line except at the anterior and posterior ends. The visceral mass is thus enclosed in a tubular sheath open at both ends. The shell secreted by the mantle is correspondingly tubular and with anterior and posterior orifices. The head is imperfectly developed and bears numerous long filaments. The foot is cylindrical and the animal is devoid of gills.



FROM PILSBRY, "MANUAL OF CONCHOLOGY"

FIG. 1.—SHELL OF DENTALIUM ELEPHANTINUM
Above, a cross-section outline of the tusk-like shell

The Scaphopoda are exclusively marine. The foot is adapted for digging and burrowing into sand, in which they lie with the posterior extremity of the shell projecting from the surface. They were originally placed in the same class (Acephala) as the Lamellibranchia; but beyond the conformation of the mantle and the digging foot there is no close resemblance to that group, whereas their possession of a radula, mandible and buccal bulb and of a stomatogastric system in their nervous organization point to affinities with the Gastropoda.

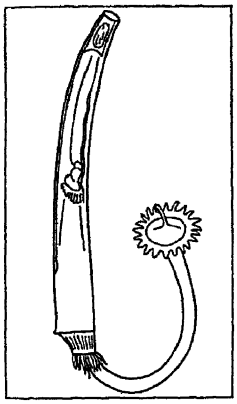


FROM LANKESTER, "TREATISE ON ZOOLOGY"

FIG. 2.—DIAGRAM OF ORGANIZATION OF DENTALIUM, LEFT SIDE VIEW
The Dentaliidae are characterised by the conical shaped foot, and the curvature of the shell

External Form.—The shell of *Dentalium* is able to contain the whole animal and is elongate, conical and slightly curved. There are two apertures in all the Scaphopod shells, a larger anterior one from which the foot projects and a smaller posterior one. The hinder end bearing this orifice is kept clear of the sand and thus admits water for respiration, and allows the excreta and faeces to be discharged when the animal is buried. The mantle-cavity is continuous from one end of the body to the other. The head and foot lie at the anterior end, the former above the latter. The head is cylindrical and bears two lobes beset with long filaments (captacula). These are mainly sensory but also serve to capture the small organisms on which the animal feeds. The foot is elongated and capable of considerable extension. Its expansible end is of great service in digging.

Internal Anatomy.—All Scaphopoda have a well-developed buccal mass with mandible and radula. From the oesophagus the food passes into the stomach, which is little differentiated and receives the ducts of a bilobed liver and a pyloric caecum. The intestine is provided with an anal gland. The circulation and respiratory system is extremely simple. The heart is rudimentary and there are no proper blood vessels. There are no specialized respiratory organs (gills) and the blood is oxygenated in the inner surface of the mantle. There are two kidneys in the mid-ventral region of the body which open to the exterior, one on each side of the anus. The nervous system consists of the same pairs of ganglia with their commissures as in the Gastropoda. The cerebral and pleural ganglia are joined to the pedal ganglia by a long connective. These animals have only three kinds of sensory organs—the captacula, apparently tactile and olfactory, the subradular organ, probably an organ of taste; and the organs of balance (otocysts), situated in the foot. The sexes are separate. The ovary and the testis are unpaired and open into the right kidney, as in the aspidobranchiate Gastropoda.



FROM JUTTINGS, "TIERWELT DER NORD- UND OSTSEE"

FIG. 3.—SIPHONODENTALIUM LOFOTENSE, SHOWING EXPANDED FOOT AND ANTERIOR END OF SHELL

Development.—This has been studied in *Dentalium*. The eggs are laid singly and segmentation is unequal and irregular. A gastrula arises through invagination, as in most Mollusca, and subsequently develops into a floating trochophore larva. A veliger stage succeeds and after five or six days the velum (girdle of cilia) atrophies and the young *Dentalium* abandons its floating life and starts to creep about on the sea-bottom. Interesting experiments have been done on this form. (*See* EXPERIMENTAL EMBRYOLOGY.)

Bionomics, Evolution, Etc.—The Scaphopoda are sedentary and live in the adult stage on the sea-bottom, into the surface layers of which they burrow and usually remain with part of the shell projecting from the surface. They are carnivorous and feed upon such small animals as Foramenifera, young bivalves, etc. The majority live in fairly deep water and (*e.g.*) in the North sea are entirely absent in the littoral zone. *Dentalium peruvianum* has been found at a depth of 2,235 fathoms (U.S.S. "Albatross"). They have a practically cosmopolitan distribution. The earliest representatives of the class appear in the Middle Silurian, some 285 fossil species being known.

BIBLIOGRAPHY.—The most important papers up to 1906 are cited by P. Pelseneer in Lankester's *Treatise on Zoology* (Pt. v. *Mollusca*). *See* also:—T. van Benthem Jutting, "Die Tierwelt der Nord-und Ostsee" IX. c. 1926; J. Henderson, "A Monograph of the North American Scaphopod Molluscs," *United States National Museum*, Bull. iii. 1920. (G. C. R.)

SCAPOLITE, a group of rock-forming minerals, which are silicates of aluminium with calcium or sodium but containing more or less chlorine, carbonate or sulphate radicals. The scapolites (Gr. σκᾶπος, rod, λίθος, stone) must be regarded as variable isomorphous mixtures of the following five components:

Ma $=3NaAlSi_3O_8{\cdot}NaCl$—chloride-marialite
MaS$=3NaAlSi_3O_8{\cdot}Na_2SO_4$—sulphate-marialite
MaC$=3NaAlSi_3O_8{\cdot}Na_2CO_3$—carbonate-marialite
MeC$=3CaAl_2Si_2O_8{\cdot}CaCO_3$—carbonate-meionite
MeS$=3CaAl_2Si_2O_8{\cdot}CaSO_4$—sulphate-meionite

It seems not improbable that in marialite, NaCl, etc., may be replaced to a limited extent by KOH, and in meionite $CaCO_3$, etc., be similarly replaced by CaF_2. The close relation which this group of minerals bears to the plagioclase felspars is apparent in the formulae indicated above. The scapolites crystallize in the tetragonal system, the crystals being prismatic hemihedral. The dominant cleavage is (100). The hardness is 5–6, while the sp.gr. varies with the composition, pure chloride marialite 2·560 carbon-

ate-meionite 2·772. The colour is usually white or grey. Between the end members, marialite and meionite, there are mixtures which have been given definite names. These include dipyre and mizzonite, and may, as in the case of the plagioclase felspars, be arbitrarily fixed as follows:

Marialite $Ma_{100} \rightarrow Ma_{80}$
Dipyre $Ma_{80}Me_{20} \rightarrow Ma_{50}Me_{50}$
Mizzonite $Ma_{50}Me_{50} \rightarrow Ma_{20}Me_{80}$
Meionite $Ma_{20}Me_{80} \rightarrow Me_{100}$

The scapolites show varying resistance to acids, the meionite-rich members being most readily attacked, CO_2 being released by HCl-HF mixtures from the carbonate meionite, while marialite is only slightly attacked. None of the scapolites have as yet been synthesized. They are destroyed by fusion, the lime-rich members giving plagioclase felspar on cooling. The commonest alteration products are calcite kaolin, white mica and zeolites. The scapolites are essentially metamorphic minerals, appearing very commonly in metamorphosed limestones.

Well-developed glassy crystals of scapolite occur in the ejected blocks of limestone of Monte Somma, Vesuvius, and large crystals occur in the apatite deposits of Bamle, southern Norway, where they arise from alteration of plagioclase felspar in gabbro. The mode of occurrence of scapolite is referred to in detail below.

(C. E. T.)

Scapolite Rocks.—According to their genesis the scapolite rocks fall naturally into four groups.

1. The scapolite limestones and contact rocks. As silicates rich in lime, it is to be expected that these minerals will be found where impure limestones have been crystallized by contact with an igneous magma. Even marialite (the variety richest in soda) occurs in this association, being principally obtained in small crystals lining cavities in ejected blocks of crystalline limestone at Vesuvius and the craters of the Eifel in Germany. Mizzonite and meionite are far more common at the contacts of limestone with intrusive masses. The minerals which accompany them are calcite, epidote, vesuvianite, garnet, wollastonite, diopside and amphibole. The scapolites are colourless, flesh-coloured, grey or greenish; occasionally they are nearly black from the presence of very small enclosures of graphitic material. They are not in very perfect crystals, though sometimes incomplete octagonal sections are visible; the tetragonal cleavage, strong double refraction and uniaxial interference figure distinguish them readily from other minerals. Commonly they weather to micaceous aggregates, but sometimes an isotropic substance of unknown nature is seen replacing them. In crystalline limestones and calc-silicate rocks they occur in small and usually inconspicuous grains mingled with the other components of the rock. Large, well-formed crystals are sometimes found in argillaceous rocks (altered calcareous shales) which have suffered thermal metamorphism. In the Pyrenees there are extensive outcrops of limestone which are penetrated by igneous rocks described as ophites (varieties of dolerite) and lherzolites (peridotites). At the contacts scapolite occurs in a great number of places, both in the limestones and in the calcareous shales which accompany them.

2. In many basic igneous rocks, such as gabbro and dolerite, scapolite replaces felspar by a secondary or metasomatic process. Some Norwegian scapolite-gabbros (or diorites) examined microscopically furnish examples of every stage of the process. The chemical changes involved are really small, one of the most important being the assumption of a small amount of chlorine in the new molecule. Often the scapolite is seen spreading through the felspar, portions being completely replaced, while others are still fresh and unaltered. The felspar does not weather, but remains fresh, and the transformation resembles metamorphism rather than weathering. It is not a superficial process, but apparently takes place at some depth under pressure, and probably through the operation of solutions or vapours containing chlorides. The basic soda-lime felspars (labradorite to anorthite) are those which undergo this type of alteration. Many instances of scapolitization have been described from the ophites (dolerites) of the Pyrenees. In the unaltered state these are ophitic and consist of pyroxene enclosing lath-shaped plagioclase felspars; the pyroxene is often changed to uralite. When the felspar is replaced by scapolite the new mineral is fresh and clear, enclosing often small grains of hornblende. Extensive recrystallization often goes on, and the ultimate product is a spotted rock with white rounded patches of scapolite surrounded by granular aggregates of clear green hornblende: in fact the original structure disappears.

3. In Norway scapolite-hornblende rocks have long been known at Oedegården and other localities. They have been called spotted gabbros, but usually do not contain felspar, the white spots being entirely scapolite while the dark matrix enveloping them is an aggregate of green or brownish hornblende. In many features they bear a close resemblance to the scapolitized ophites of the Pyrenees. It has been suggested that the conversion of their original felspar (for there can be no doubt that they were once gabbros, consisting of plagioclase and pyroxene) into scapolite is due to the percolation of chloride solutions along lines of weakness, or planes of solubility, filling cavities etched in the substance of the mineral. Subsequently the chlorides were absorbed, and *pari passu* the felspar was transformed into scapolite. But it is found that in these gabbros there are veins of a chlorine-bearing apatite, which must have been deposited by gases or fluids ascending from below. This suggests that a pneumatolytic process has been at work, similar to that by which, around intrusions of granite, veins rich in tourmaline have been laid down, and the surrounding rocks at the same time permeated by that mineral. In the composition of the active gases a striking difference is shown, for those which emanate from the granites are mainly fluorine and boron, while those which come from the gabbro are principally chlorine and phosphorus. In one case the felspar is replaced by quartz and white mica (in greisen) or quartz and tourmaline (in schorl rocks); in the other case scapolite is the principal new product. The analogy is a very close one, and this theory receives much support from the fact that in Canada (at various places in Ottawa and Ontario) there are numerous valuable apatite vein-deposits. They lie in basic rocks such as gabbro and pyroxenite, and these in the neighbourhood of the veins have been extensively scapolitized, like the spotted gabbros of Norway.

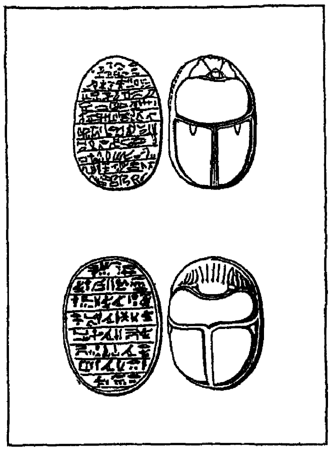
4. In many parts of the world metamorphic rocks of gneissose character occur containing scapolite as an essential constituent. Their origin is often obscure, but it is probable that they are of two kinds. One series is essentially igneous (orthogneisses); usually they contain pale green pyroxene, a variable amount of felspar, sphene, iron oxides. Quartz, rutile, green hornblende and biotite are often present, while garnet occurs sometimes; hypersthene is rare. They occur along with other types of pyroxene gneiss, hornblende gneiss, amphibolites, etc. In many of them there is no reason to doubt that the scapolite is a primary mineral. Other scapolite gneisses equally metamorphic in aspect and structure appear to be sedimentary rocks. Many of them contain calcite or are very rich in calc-silicates (wollastonite, diopside, etc.), which suggests that they were originally impure limestones. The frequent association of this type with graphitic-schists and andalusite-schists makes this correlation in every way probable.

(J. S. F.)

SCARAB (Lat. *scarabaeus*, connected with Gr. κάραβος), literally a beetle, and derivatively an Egyptian symbol in the form of a beetle. The Egyptian hieroglyph  pictures a dung beetle (*Scarabaeus sacer*), which lays its egg in a ball of dung, and may be seen on sandy slopes in hot sunshine compacting the pellet by pushing it backward uphill with its hind legs and allowing it to roll down again, eventually reaching a place of deposit. Whatever the Egyptians may have understood by its actions, they compared its pellet to the globe of the sun. The beetle is common on both shores of the Mediterranean; the Egyptian name was *kheperer, kheperi*, and the sign spelt the verb *khōpi(r)* meaning "become" and perhaps "create," also the substantive "phenomenon" or "marvel." The insect was sacred to the sun-god in his form *khepēri* at Heliopolis, and has been found mummified. A colossal scarabaeus of granite in the British Museum probably came from the temple of Heliopolis. The scarabaeus was much used in Egyptian religions, appearing sometimes with outstretched wings or with a ram's head and horns as the vivifying

soul. It is often seen in this guise on coffins of the New Kingdom and later, when it also became the custom to place in the bandages of the mummy a large stone scarab engraved with a chapter of the Book of the Dead. This chapter, the 64th, identified the object with the heart of the deceased and conjured it not to betray him in the judgment before Osiris. A winged scarab might also be laid on the breast; and later a number of scarabs were placed about the body. These are often of hard stone and of fine workmanship. Another and even more important class of Egyptian antiquities is in the form of scarabs, pierced longitudinally for a swivel or for threading, and having the bases flat and engraved with designs. These were intended principally for seals, but might also be used as beads or ornaments. They are thus found, engraved or plain, strung on necklaces, and amethyst scarabs with plain bases are common articles of Middle Kingdom jewellery. But the employment of scarabs as seals is proved by the impressions found on sealed documents of the Middle and New Kingdom, on several occasions the impressed clay seals alone have been found hardened and preserved by the fire which had destroyed the archives themselves. The seal type of scarabaei is extremely abundant, and the designs engraved beneath them show endless variety. Some have inscriptions carefully executed, but frequently corrupted by illiterate copying until they became meaningless. The inscriptions are sometimes "mottoes" having reference to places, deities, etc., or containing words of good omen or friendly wishes, *e.g.*, "Memphis is mighty for ever," "Ammon protecteth," "Mūt give thee long life," "Bubastis grant a good New Year," "May thy name endure and a son be born thee." Such are of the New Kingdom or later. Names and titles of officials appear, most commonly in the Middle Kingdom.

Historically the most valuable class is of those which bear royal names, ranging from Senusret I. of the XIIth Dynasty to the end of the XXVIth Dynasty. Certain great kings are commemorated on scarabs of periods long subsequent to them. Thus Cheops (Khufu), of the IVth Dynasty, appears on examples of the latest Pharaonic age, scarabs having been unknown in his time, and Tuthmosis III. is found at all times after the XVIIIth Dynasty. But after the XIIth Dynasty the royal names are of contemporary workmanship, and the differences of style and pattern make it possible to group unknown kings with those who are known historically; the names of the Hyksos kings have been principally recovered from collections of scarab-seals. Scarab-shaped seals are traceable as far back as about the VIth Dynasty. They became abundant under the XIIth and continued until almost the end of the native rule. As seals they took the place of the earlier cylinders and "button-seals." Considering the life-history of the scarabaeus and its meaning as a hieroglyph, it may well be that the scarab impressing the clay had a symbolic significance; however that may be, the oval form was well adapted for seal-stones and for the bezels of finger rings. In this situation the scarabs were often mounted with a rim of gold or silver round the edge. Rings of stone, glass or metal, with engraved bezels of the same material, and eventually Greek gem rings, gradually displaced them.



FROM PETRIE, "SCARABS AND CYLINDERS" (HAZELL, WATSON & VINEY)
EGYPTIAN HEART SCARABS OF THE 18TH DYNASTY

A series of exceptionally large scarabs was engraved in the reign of Amenophis III., *c.* 1450 B.C., all being inscribed with his name together with that of Queen Tiye and her parentage. At present five varieties are known. The simplest commemorates his queen and the north and south limits of his empire; another dated in the first year, a great battue of wild cattle; the third, the arrival of the princess Gilukhipa of Mitanni in the tenth year; the fourth (many specimens), the number of lions slain by the king down to his tenth year; the last, the cutting of the lake of Zarukhe in the eleventh year.

Egyptian scarabs were carried by trade to most of the islands and shores of the eastern Mediterranean and to Mesopotamia. The Greeks, especially in their Egyptian colony of Naucratis (*q.v.*), imitated them in soft paste. The finest Etruscan gems of the 6th and 5th centuries B.C. are in the form of scarabs, perhaps suggested by the Egyptian. The forgers of antiquities have carried on a brisk trade in scarabs for more than a century.

See P. E. Newberry, *Scarabs* (London, 1906); Hall, *Catalogue of Scarabs, British Museum,* i. (1913); Petrie, *Scarabs;* also art. GEM, especially for later scarabaeoid gems. (F. LL. G.; H. R. H.)

SCARAMOUCH, properly a buffoon, used later colloquially for a ne'er-do-well. The name was that of a stock character in 17th century Italian farce, *Scaramuccia* (*i.e.*, literally "skirmish"), who, attired usually in a black Spanish dress, burlesquing a "don," was beaten by Harlequin for his boasting and cowardice.

SCARBOROUGH, a municipal borough in the North Riding of Yorkshire, England, 231 m. N. of London and 42 m. N.E. of York by the L.N.E. railway. Pop. (1931) 41,791. It is situated on the N.E. coast of Yorkshire, where a hammer-like peninsula of high land projects eastwards, separating the North and South Bays. The modern town fringes both bays and extends a considerable distance inland. The peninsula is crowned by a 12th century castle, but such a natural stronghold was occupied earlier. The remains of a Roman signalling station were excavated here in 1925, and during the excavations, relics of a bronze age village were discovered. The site had long been abandoned when the Romans came and erected there one of a series of signalling stations to aid in the defence of Britain against Saxon raiders. It was built about 370–395, not as an object of defence but as a watch tower.

After the Roman occupation, the site lay waste until about 1,000 when a chapel was built within the partly ruined walls of the Roman tower, and this was probably destroyed when Harold Hardrada of Norway sacked and burnt the town in 1066. The Roman remains were cleared when the castle was first built in stone in 1148–68 to replace an earlier Norman structure, probably of wood. The present ruins include a lofty Norman keep, and the dyke or moat on the landward side, which was simply a ditch, making the approach on this side more difficult. A wall with towers also protects the castle in this direction. Near the landward side of the dyke is the church of St. Mary, occupying the site of a Cistercian monastery of 1198. It is transitional Norman and Early English with later additions.

History.—Although there is no mention of Scarborough in the Domesday Survey, the remains of Roman roads leading to the town indicate that it was, in early times, a place of importance. It was a "walled city" in 1181, when granted its first charter, which gave the burgesses all liberties in the same way as the citizens of York. The strength of the castle was greatly increased by Henry II., and a new chapel was completed on the site of the old one in 1189. Henry III., in 1253, granted that a court of pleas should be held at Scarborough by the justices who went to hold common pleas at York; he also gave the corporation a gild merchant and granted a yearly fair, which was originally held on the sands. During his reign the Barbican, Causeway, and present gateways of the castle were built and the whole was made an impregnable fortress. The Scots came to Scarborough in 1318, and took and burned the town, but the castle proved too strong for them. The town was taken away from the burgesses by Edward II., but was restored to them by Edward III. in 1327, and a charter of 1356 confirms the privileges of the borough.

By the charter of 1485, Richard III. appointed that the town should be governed by a mayor, a sheriff, and twelve aldermen and that, together with the mayor of Whallesgrave, it should be a county of itself. On the death of Richard III., however, it took no effect and the corporation retained its old mode of government; a mayor was not appointed until 1684. When Henry VIII. passed the Act for the Suppression of the monasteries, the people of Yorkshire unsuccessfully besieged Scarborough castle, which was held for the king. It was repaired during the reign of Elizabeth. During the Civil War, the Royalists held the town and

castle, which were besieged by the Parliamentary forces in 1644. The town was taken in 1645 and after twelve months the castle fell to the Parliamentarians. It underwent another siege in 1648 after Scarborough revolted to the king, and after three months it surrendered and the castle was ordered to be demolished. This was done by blowing down the north-western front with gunpowder in 1650. During the rebellion of 1745, the castle was partly repaired.

The development of Scarborough as a watering place dates from 1620, when two mineral springs were discovered. They are now contained in the garden of the Spa house near the shore of the South Bay, but are relatively unimportant. West of Scarborough lie the high moors intersected by narrow well wooded valleys and to the south lies the Vale of Pickering. Scarborough is thus a tourist centre as well as a seaside resort, and annual sports festivals provide an additional attraction. The harbour, enclosed by piers and divided into two basins, lies on the south side of the castle peninsula. It is dry at low tide, but it accessible at spring tides to vessels of 13 ft. draught, and is largely used by fishing boats. There is also a floating dock for the repair of ships, and a scheme to meet the growing demand for the improvement of the harbour, was begun in 1927. Accommodation has also been made for "fishing-girts." The fishing industry is now less important than at one time. Jet was formerly an important manufacture. The main sea-coast road from Whitby via Scarborough to Bridlington has been improved and the New Valley Bridge built.

Scarborough was shelled by German cruisers in 1914, when the castle was damaged, the coast guard station was struck and the barracks were destroyed. It was also visited by enemy submarines in 1917.

Two members were returned to parliament from 1295–1885, when the number was reduced to one. It now forms part of the Scarborough and Whitby Parliamentary division. (M. K. M.)

SCARIFIER: *see* CULTIVATING MACHINERY.

SCARLATTI, ALESSANDRO (1659–1725), Italian musical composer, was born in Sicily in 1659. He is generally said to have been a pupil of Carissimi in Rome, and he probably had some connection with northern Italy, since his early works show the influence of Stradella and Legrenzi. The production at Rome of his opera *Gli Equivoci nell' amore* (1679) gained him the protection of Queen Christina of Sweden, and he became her maestro di capella. In February 1684 he became maestro di capella to the viceroy of Naples, and here he produced a long series of operas, remarkable chiefly for their fluency. In 1702 he left Naples and did not return until the Spanish domination had been superseded by that of the Austrians. In the interval he enjoyed the patronage of Ferdinand III. of Tuscany, for whose private theatre near Florence he composed operas, and of Cardinal Ottoboni, who made him his maestro di capella, and procured him a similar post at the church of S. Maria Maggiore in Rome (1703). After visiting Venice and Urbino in 1707, he took up his duties at Naples again in 1708, and remained there until 1717. It was at the Teatro Capranica in Rome that he produced some of his finest operas (*Telemaco*, 1718; *Marco Attilio Regolo*, 1719; *Griselda*, 1721), as well as some noble specimens of church music, including a mass for chorus and orchestra, composed in honour of St. Cecilia for Cardinal Acquaviva in 1721. His last work on a large scale appears to have been the unfinished serenata for the marriage of the prince of Stigliano (1723); he died at Naples on the 24th of October 1725.

Scarlatti's music forms the most important link between the tentative "new music" of the 17th century and the classical school of the 18th, which culminated in Mozart. His early operas (*Gli Equivoci nel sembiante* [1679]; *L' Honestà negli amori* [1680]; *Pompeo* [1683], containing the well-known airs "O cessate di piagarmi" and "Toglietemi la vita ancor," and others down to about 1685) retain the older cadences in their recitatives. By 1686 he had definitely established the "Italian overture" form (second edition of *Dal male il bene*), and had abandoned the ground bass and the binary air in two stanzas in favour of the ternary or *da capo* type of air. His best operas of this period are *La Rosaura* (1690, printed by the *Gesellschaft für Musikforschung*), and *Pirro e Demetrio* (1694), in which occur the songs "Rugiadose, odorose," "Ben ti sta, traditor." *Mitridate Eupatore*, composed for Venice in 1707, contains music far in advance of anything that Scarlatti had written for Naples, both in technique and in intellectual power. The later Neapolitan operas are *L'Amor volubile e tiranno* (1709); *La Principessa fedele* (1712); *Tigrane*, 1715.

Scarlatti's claim to remembrance rests on the fact that he practically created the language of classical music. He extended the old forms, and filled them with melody unrivalled for purity and serenity, based on a far-reaching foundation of modern harmony and tonality, combined with great power of thematic development.

SCARLATTI, DOMENICO (1685–1757), eldest son of Alessandro Scarlatti, also a composer, was born at Naples on the 26th of October 1685. Presumably he studied first under his father, but he was in all probability also a pupil of Gaetano Greco. In 1704 he remodelled Pollaroli's *Irene* for performance at Naples. In 1709 Domenico entered the service of Marie Casimire, queen of Poland, then living in Rome, and composed several operas for her private theatre. He was Maestro di Cappella at St. Peter's from 1715 to 1719, and in the latter year came to London to direct his opera *Narciso* at the King's Theatre. In 1720 or 1721 he went to Lisbon, where he taught music to the princess Magdalena Theresia. He was at Naples again in 1725, but in 1729 went to Madrid as music master to the princess, who had married into the Spanish royal house. He is supposed to have died in 1757.

Modern Printed Editions.—Clementi's *Practical Harmony* (4 vols., 1815); Czerny's edition; J. H. Farrenc, *Le Trésor des pianistes* (21 vols., 1861–72). *See* Grove's *Dictionary of Music and Musicians* (1928).

SCARLET FEVER or **SCARLATINA,** names applied indifferently to an acute infectious disease, characterized by high fever, accompanied with sore throat and a diffuse red rash upon the skin. This fever appears to have been first accurately described by Sydenham in 1676, before which period it had evidently been confounded with smallpox and measles. It is generally believed that the disease is caused by haemolytic streptococci. Klein in 1885 isolated a streptococcus which he termed the streptococcus scarlatinae. The scarlatinal throat is the chief habitat of the organism, though it has been found both by Klein and other observers in the discharges from the ears of scarlet fever patients. Mervyn Gordon also isolated from cases the streptococcus conglomerulatus. It is possible that septic cases of scarlet fever are the result of a mixed infection. The serum of patients has been found to contain agglutins to streptococci from cases of erysipelas, septicaemia and puerperal fever, as well as to the streptococci scarlatinae. F. B. Mallory in 1904 published his discovery of "protozoonlike" bodies in the cells of the epidermis. Other observers have found them in the skin of fatal cases, but failed to find them in the living. The contagion of scarlet fever takes place from a previous case either by the skin during the early stages of the disease or by the nasal or aural discharges of a patient. It may be conveyed by any article of clothing or furniture or by any person that has been in contact with a scarlet fever patient. Infectivity may also take place through a contaminated milk supply, as in the Marylebone epidemic, 1885. Klein here found a disorder in cows which he considered analogous to scarlatina and communicable to man.

The period of incubation in scarlet fever may be as short as one or two days, but in most instances it is probably less than a week. The invasion of this fever is generally sudden, consisting in rigors, vomiting and sore throat, together with a rapid rise of temperature and increase in the pulse. About twenty-four hours later the characteristic eruption appears. It is first seen on the neck, chest, arms and hands, but quickly spreads all over the body, although it is not distinctly marked on the face. This rash consists of minute thickly-set red spots, which coalesce to form a general diffuse redness, in appearance not unlike that produced by the application of mustard to the skin. In ordinary cases the rash takes about two days to come out, then begins to fade, and by the end of a week from its first appearance it is usually gone.

The severity of a case is in some degree measured by the copiousness and brilliancy of the rash, except in the malignant varieties, where there may be little or no eruption. The tongue, which at first was furred, becomes about the fourth or fifth day denuded of its epithelium and acquires the peculiar "strawberry" appearance characteristic of this fever. The interior of the throat is red and swollen, especially the uvula, soft palate and tonsils, and much secretion exudes from the inflamed surface. There is also tenderness and slight swelling of the glands under the jaw. In favourable cases the fever departs with the disappearance of the eruption and convalescence sets in with peeling of the cuticle, which first shows itself about the neck, and proceeds slowly over the entire body. Where the skin is thin the desquamation is in the form of fine branny scales; but where it is thicker, as about the hands and feet, it comes off in large pieces, which sometimes assume the form of casts of the fingers or toes. The duration of this process is variable, but it is rarely complete before the end of six or eight weeks, and not unfrequently goes on for several weeks beyond that period. It is during this stage that complications are apt to appear.

Scarlet fever shows itself in certain well-marked varieties, of which the following are the chief:—

1. **Scarlatina Simplex** is the most common form; the symptoms are moderate, and the case usually runs a favourable course. In some instances evidences of the disease are so slight that they escape observation and only become known by the patient infecting another person or subsequently suffering from some of the complications associated with it.

2. **Septic Scarlatina** or **Scarlatina Anginosa** is a more severe form, particularly as regards the throat symptoms. The rash may be well marked or not, but it is often slow in developing and in subsiding. There is intense inflammation of the throat, the tonsils, uvula and soft palate being swollen and ulcerated, or bearing membranous patches not unlike those of diphtheria, while the lymphatic glands in the neck are enlarged and indurated and often suppurate. This form of the disease is marked by great exhaustion and the gradual development of acute septicaemia, with sweating, albuminuria, delirium and septic rash. Some of these cases bacteriologically show the presence of B. diphtheria.

3. **Toxic Scarlatina (Scarlatina Maligna).** In this form the gravity of the condition is due to intense poisoning. The attack sets in with great violence and the patient sinks from the very first. The rash either does not come out at all or is of the slightest amount and of livid rather than scarlet appearance, while the throat symptoms are often not prominent. A further example of a malignant form is occasionally observed in cases where the rash, which had previously been well developed, suddenly recedes, and convulsions or other nervous phenomena and rapid death supervene.

The complications and effects of scarlet fever are among the most important features in this disease, although their occurrence is exceptional. The most serious is inflammation of the kidneys, which is specially apt to appear during convalescence. In a large number of instances it comes on insidiously. One of the most prominent symptoms is swelling of the eyelids. The urine is diminished in quantity, smoky or red from the presence of blood and contains a large quantity of albumen and casts. Mucopurulent rhinorrhoea and rheumatism are other complications. One of the commonest is suppuration of the ears due to extension of the inflammatory process from the throat along the Eustachian tube into the middle ear. This often leads to permanent ear-discharge, with deafness from the disease affecting the inner ear and temporal bone; the condition is dangerous from its proximity to the brain. Other maladies affecting the heart, lungs, pleura, etc., occasionally arise in connection with scarlet fever, but are of less occurrence than those previously mentioned.

Treatment.—In the treatment of scarlet fever, one of the first requirements is isolation of the case, to limit spread of the disease. In convalescence, inunction of the body with carbolized oil (1 in 40) and the frequent use of a bath containing soda, are to be recommended. It is seldom that a patient who has suffered from scarlet fever can safely go about before the expiry of eight weeks, while the period may be considerably prolonged, should any nasal or aural discharge continue. As to general management in favourable cases little is required beyond careful nursing and feeding. The treatment of kidney complications is that of acute Bright's disease. A hot-air bath or wet pack is often useful. When otorrhoea is present the canal must be kept as aseptic as possible. The ears should be carefully syringed every four hours with an antiseptic solution and dried, and a little iodoform inserted into the meatus. Complications such as mastoid disease require special treatment.

Serumtherapy.—Dr. Besredka prepared a serum from the blood of fatal cases, and in the serum prepared at the Pasteur Institute some twenty separate strains of streptococci are used. In using serums, early and large dosage is necessary. Palmirski and Zebrowski prepared a serum from the streptococcus conglomerulatus, which was used with success in the children's hospital at Warsaw. For the Dick method of intradermal inoculation *see* MEDICAL RESEARCH.

SCARLETT, SIR JAMES YORKE (1799–1871), British general, was the second son of the 1st Baron Abinger. Educated at Eton and Trinity College, Cambridge, he entered the army in 1818, and in 1830 became major in the 5th Dragoon Guards. From 1836 until 1841 he was Conservative M.P. for Guildford. In 1840 he obtained the command of his regiment, which he held for nearly fourteen years. In the Crimean War the 5th Dragoon Guards formed part of the Heavy Cavalry Brigade (of which Scarlett was appointed brigadier); it was sent to the Black Sea in 1854, and suffered very heavily from cholera in the camps of Varna. At Balaklava the Heavy Brigade achieved a magnificent success against the Russian cavalry, and had the brigadier (who in the previous charge had been in the thickest of the mêlée) been allowed to advance as he wished, might have converted the disastrous charge of the Light Brigade into a substantial success. (*See* BALACLAVA and CRIMEAN WAR.) For his services on this day Scarlett was promoted major-general, and in 1855 was made K.C.B. After a short absence in England he returned to the Crimea with the local rank of lieutenant-general to command the British cavalry. Scarlett commanded the cavalry at Aldershot until 1860, was adjutant-general of the army from 1860 to 1865, and was commander at Aldershot 1865–70. He died in 1871.

SCARPANTO: *see* KARPATHOS.

SCARRON, PAUL (1610–1660), French poet, dramatist, novelist and husband of Madame de Maintenon, was baptized on the 4th of July 1610. His father, of the same name, was a member of the *parlement* of Paris. Paul the younger became an *abbé* when he was nineteen, and in 1633 entered the service of Charles de Beaumanoir, bishop of Le Mans, with whom he travelled to Rome in 1635. Finding a patron in Marie de Hautefort, he became a well-known figure in literary and fashionable society. An improbable story is told on the authority of La Beaumelle (*Mémoires . . . de Mme. de Maintenon*) that—when in residence at his canonry of Le Mans—he once tarred and feathered himself as a carnival freak and, being obliged to take refuge from popular wrath in a swamp, was crippled from rheumatism. What is certain is that Scarron, after having been in perfect health for nearly thirty years, passed twenty more in a state of miserable deformity and pain. His head and body were twisted, and his legs became useless. He bore up against his sufferings with invincible courage, though his circumstances were further complicated by a series of lawsuits with his stepmother over his father's property, and by the poverty and misconduct of his sisters, whom he supported. Scarron returned to Paris in 1640, and in 1643 appeared a *Recueil de quelques vers burlesques,* and in the next year *Typhon ou la gigantomachie.* At Le Mans he had conceived the idea of the *Roman comique,* the first part of which was printed in 1651. In 1645 was performed the comedy of *Jodelet, ou le maître valet,* the name of which was derived from the actor who took the principal part. *Jodelet* was the first of many French plays in which the humour depends on the valet who takes the part of master, an idea that Scarron borrowed from the Spanish. After a short visit to Le Mans in 1646, he returned to Paris, and worked hard for the bookseller Quinet, calling his works his *"marquisat de*

Quinet." He had also a pension from Fouquet, and one from the queen, which was withdrawn because he was suspected of Frondeur sentiments. When Mazarin received the dedication of *Typhon* coldly, Scarron changed it to a burlesque on the minister. In 1651 he definitely took the side of the Fronde in a *Mazarinade*, a violent pamphlet. He now had no resources but his "*marquisat.*"

In his early years he had been something of a libertine. In 1649 a penniless lady of good family, Céleste Palaiseau, kept his house in the Rue d'Enfer, and tried to reform the gay company which assembled there. But in 1652, sixteen years after he had become almost entirely paralysed, he married a girl of much beauty and no fortune, Françoise d'Aubigné, afterwards famous as Madame de Maintenon (*q.v.*). Scarron had long been able to endure life only by the aid of constant doses of opium, and he died on the 6th of October 1660.

Scarron's work is very abundant and very unequal. The piece most famous in his own day, his *Virgile travesti* (1648–1653), is now thought a somewhat ignoble waste of singular powers for burlesque. But the *Roman comique* (1651–1657) is a work the merit of which is denied by no competent judge. Unfinished, and a little desultory, this history of a troop of strolling actors is almost the first French novel, in point of date, which shows real power of painting manners and character, and is singularly vivid. It is in the style of the Spanish picaresque romance, and furnished Théophile Gautier with the idea and with some of the details of his *Capitaine Fracasse*. Scarron also wrote some shorter novels: *La Précaution inutile,* which inspired Sedaine's *Gageure imprévue; Les Hypocrites,* to which *Tartuffe* owes something, and others. Of his plays *Jodelet* (1645) and *Don Japhet d'Arménie* (1653) are the best.

The most complete edition of his works is by La Martinière, 1737 (10 vols., Amsterdam). The *Roman comique* and the *Énéide travestie* were edited by Victor Fournel in 1857 and 1858. Among the contemporary notices of Scarron, that contained in the *Historiettes* of Tallemant des Réaux is the most accurate. The most important modern works on the subject are *Scarron et le genre burlesque* (1888) by Paul Morillot; a biography by J. J. Jusserand in English, prefixed to his edition of *The Comical Romance and other tales by Paul Scarron, done into English by Tom Brown of Shifnal, John Savage and others* (2 vols., 1892); and *Paul Scarron et Françoise d'Aubigné d'après des documents nouveaux* (1894) by A. de Boislisle.

SCAUP, the wild-fowler's abridgement of SCAUP-DUCK, a diving duck (*Nyroca marila*), so called "because she feeds upon *scaup, i.e.,* broken shell-fish." It is an abundant bird round the coasts of most of the northern hemisphere; it repairs inland in spring to breed in Iceland, Lapland, Siberia, and the fur countries of America. The scaup-duck has considerable likeness to the pochard (*q.v.*), both in habits and appearance; but it more generally affects salt water, and the head of the male is black, glossed with green; in North America, a second species smaller than the ordinary one is also found, the lesser scaup, *N. affinis.* The female scaup-duck can be distinguished from the female pochard by her broad white face.

SCAURUS, MARCUS AEMILIUS, was the son of Marcus Aemilius Scaurus (*c.* 163–88 B.C.), who was curule aedile, praetor and consul in 115, censor in 109, and in charge (104) of the corn supply at Ostia. The father belonged to the moderate aristocratical party, and was frequently in difficulties with extremists on either side. Though not a great orator, his speeches were weighty and impressive. The son served during the 3rd Mithradatic War (74–61 B.C.) as quaestor to Pompey, by whom he was sent to Judaea to settle the quarrel between Hyrcanus and Aristobulus. Scaurus decided in favour of the latter, who was able to offer more money. On his arrival in Syria, Pompey reversed the decision, but, ignoring the charge of bribery brought against Scaurus, left him in command of the district. An incidental campaign against Aretas, king of the Nabataeans, was ended by the payment of 300 talents by Aretas to secure his possessions. This agreement is represented on coins of Scaurus. As curule aedile in 58, Scaurus celebrated the public games on a scale of magnificence never seen before. The show included many animals never before seen in Rome, and a wooden theatre was erected to hold 80,000 spectators. In 56 Scaurus was praetor, and in the following year governor of Sardinia. On his return to Rome (54) he was accused of extortion in his province. Cicero and five others (amongst them the famous Q. Hortensius) undertook his defence, and, although there was no doubt of his guilt, he was acquitted. During the same year, however (according to some, two years later, under Pompey's new law), Scaurus was condemned on a charge of illegal practices as a candidate for the consulship, and was exiled.

See Josephus, *Antiq.* xiv. 3–5, *Bell. Jud.* i. 7; Appian, *Syr.* 51, *Bell. civ.* ii. 24; Pliny, *Nat. Hist.* xxxvi. 24; Cicero, *Pro Sestio,* 54, fragments of *Pro Scauro,* numerous references in the *Letters;* Asconius, *Argumentum in Scaurum. See* also, for both the above, AEMILIUS (Nos. 140, 141) in Pauly-Wissowa's *Realencyclopädie der classischen Altertumswissenschaft,* i. pt. 1. (1894), and Smith's *Dictionary of Greek and Roman Biography, s.v.* Scaurus.

SCAVENGER, now one who cleans the streets, removes refuse, generally a workman employed by the local public health authority (*see* DESTRUCTORS; REFUSE DISPOSAL).

SCAVENGER'S DAUGHTER (corruption of Skevington's or Skeffington's Daughter), an instrument of torture in use during the 16th century in England. It was invented by Sir W. Skevington, lieutenant of the Tower in the reign of Henry VIII. It consisted of a wide iron hoop which by means of screws was tightened round the victim's body until the blood was forced from the nose and ears, and sometimes from the hands and feet.

SCEPTICISM means in Greek philosophical (σκέπτομαι) usage to hesitate, to reflect, to examine, to consider pros and cons, to be unable to arrive at a decision or to rest content with surmise. Strictly defined, it is the denial of the possibility of knowing reality; that is to say, the human mind, by its very constitution, can never comprehend the ultimate nature of things. But this meaning belongs to the rarefied region of pure theory; so much so that complete denial has been the exception even among professional thinkers. Hence the historical importance of the less stringent, even popular usage. For, in general acceptation, scepticism suggests denial of current or customary beliefs. Its assault is by no means confined to theology, as is often supposed.

Taken thus as a repudiation of traditional or authoritative views, it tallies with the stricter philosophical definition in that historically, scepticism has flourished most during periods of transition when attacks upon previous systematic (or even common sense) constructions were rife. Obvious examples are furnished by the assaults of the Sophists upon the Greek cosmologists; of Pyrrho and his pupils upon the followers of Plato and Aristotle; of the Middle and New Academies upon Chrysippus and the Stoics; of Sextus Empiricus upon all the principles of Graeco-Roman thought; of Montaigne upon scholasticism; of Glanvil upon the crusted Aristotelians of the Oxford schools; of Locke upon certain aspects of Cartesianism; of Hume upon Locke and the doctrine of representative perception; of Kant upon natural theology; of L. Feuerbach upon Hegel; of agnostics upon the theological interpretation of nature and man; of Nietzsche upon the practical postulates of European Christendom; and of Pragmatism upon Idealism.

ANCIENT PERIOD

For philosophical thought and practical life alike, scepticism presupposes the existence of theories and socio-political situations which lay themselves open to attack. Accordingly, in the western world, it dates (*c.* 440 B.C.) from the Greek Sophists (*q.v.*) who not only impugned current cosmological speculations, but also impeached the ethical judgments peculiar to the Hellenic "city-state," Athens particularly. Their scepticism was general rather than systematic, political as well as theoretical. Hence, the most thoroughgoing and persistent scepticism known to us arose with the profound changes wrought by Alexander the Great, the decline of the Hellenic type of civil polity, and the gradual exhaustion of original thought during the Roman Republic and Empire. Pyrrho of Elis (*c.* 300 B.C.), whose name furnishes the synonym for philosophical scepticism; his pupil, Timon of Phlius (*c.* 250 B.C.); Carneades (*c.* 150 B.C.), above all Aenesidemus (*c.* A.D. 50) and Sextus Empiricus (*c.* A.D. 200) are the prominent

figures. During the interval between the Sophists and Timon, scepticism was stayed by the personality of Socrates, and by the constructive systems of Plato and Aristotle.

Scepticism, as a distinct school, begins with Pyrrho of Elis, who maintained that knowledge of things is impossible and that we must assume an attitude of reserve (ἐποχή). The Pyrrhonists were consistent enough to extend their doubt even to their own principle of doubt. They thus attempted to make their scepticism universal, and to escape the reproach of basing it upon a fresh dogmatism. Mental imperturbability (ἀταραξία) was the result to be attained by cultivating such a frame of mind. The happiness or satisfaction of the individual was the end which dominated this scepticism as well as the contemporary systems of Stoicism and Epicureanism, and the three Schools agree that it consists in tranquillity or self-centred indifference. It is men's opinions or unwarranted judgments about things, say the sceptics, which betray them into desire, and painful effort and disappointment. From all this the man who abstains from judging one state to be preferable to another is delivered. But, as complete inactivity would have been synonymous with death, it appears to have been admitted that the sceptic, while retaining his consciousness of the complete uncertainty enveloping every step, might follow custom in daily affairs.

Sextus Empiricus presented the sceptical arguments clearly, with special reference to Stoic materialism. Since later scepticism up to Hume's day went no further, it may be well to summarize the ten characteristic ways of procedure (tropes) formulated, possibly, with Aristotle's list of categories in mind. Desirous of disabling assent to any dogmatic view Sextus, following Aenesidemus, tries to show why a criterion of truth is impossible. It is to be remembered that the common effort of the dogmatic schools was to bestow the boon of independent tranquillity upon men. To this end they presumed some knowledge of the nature of the world, which played the part of an external support. Thus, for example, the Stoics taught that sensations produce modifications within the mind, and these, in turn, represent or symbolize objects. The presentations ("phantasies" or images) are "affections occurring in the soul, revealing both themselves and that which caused them." The sceptics held such doctrines to be unnecessary and impossible. Sensations or ideas, being states of individual subjectivity, men can know nothing save their own inward experiences. Hence the intent of the "tropes." (1) Animals differ in their modes of perception, because they differ in the development of their senses. (2) Men similarly differ from each other. (3) The sense-organs differ, so that objects perceived by this or that sense present contrasted aspects. Did we possess more senses, unknown aspects of objects might appear. (4) The moods of precipients differ, and make it impossible to discern which affords true information about objects. (5) Objects differ according to their distance and position—the stick seems bent when thrust into water. (6) The organs of sense-perception constitute a medium through which the object must be perceived; hence objects cannot be known directly. (7) The modes of objects, never the objects themselves, appear to us. (8) Everything in the external world is relative, not merely to the percipient, but to everything else. (9) Associations are of such a nature that we see things in false perspective, stressing the unfamiliar, for instance, and accepting the familiar without question. (10) Consideration of mankind shows that customs, opinions, manners, institutions, laws and beliefs are of the most diverse; even in the essential matter of right and wrong, no universal standard exists. Allowing that such qualities as truth, capacity to appeal to sensibility, and intelligibility are intrinsic to objects, it follows that "(1) nothing is self-evident, for if things were certain of themselves men would not differ about them; (2) nor can anything be made certain by proof; because we must either arrive in the process at something self-evident or involve ourselves in an endless regress." Accordingly, it is out of the question to argue from "signs" to things signified, and cause as an effective component of phenomena disappears. To be beyond reach of fear or doubt or other disturbance, a man must retire into himself. Such is the theory. For the rest, he might (often did) acquiesce practically in the Roman conviction of "manifest destiny," to which Carneades would have allowed a measure of probability.

TRANSITION

The changes and disturbances which accompanied the dissolution of the Roman Empire, the gradual formation thereafter of a new philosophical synthesis within the Church, and lack of contact with Greek thought prevented for centuries anything like a revival of ancient scepticism. The *Sic et Non* of Abelard (d. 1142) with its list of contradictories about 158 questions, recalls the outlook of the "tropes," but there is no reason to regard them as sources; the same may be said of the critical subtleties of Occam (d. 1347). During the Italian Renaissance revolts against dogma and clericalism appeared, but no systematic scepticism. Nor can it be affirmed that French scepticism thereafter, although its debt to the Greek schools is obvious, became definitely systematic. Montaigne (1533–92), a practical sceptic in his attack upon abuses, diffused an atmosphere of inquiry; so did Charron (1541–1603) in his philosophy of living and appeal to natural reason. Sanchez, in his *Tractatus de multum nobili et prima universali scientia quod nihil scitur* (*A Treatise on the Noble and High Science of Nescience,* 1581), with its derivation of knowledge from the senses; and la Mothe-le-Vayer (1586–1672), who calls Sextus Empiricus "our beloved sceptic," paved the way for Bayle's *Dictionnaire historique et critique* (1697), a quarry for contradictions calculated to set natural reason and supernatural revelation by the ears. Bayle maintained that the dubiety of knowledge points to renunciation of inquiry and acceptance of revelation. In a word, be reason what it may, the authority of faith in its own sphere remains unimpaired. Hence we have a form of Christian scepticism, either genuine or assumed as a precaution.

PASCAL

The typical and most eminent example of the Christian sceptic is Pascal (1623–62). The form of the *Pensées* forbids the attempt to evolve from their detached utterances any coherent system. For, though he says "Pyrrhonism is the truth," "he who flouts philosophy is the veritable philosopher," or, again, "Abase thyself, helpless reason; be silent, thou imbecile nature," other passages recognize the validity of reason in its proper place. But what he everywhere emphatically denies is the possibility of reaching by the unassisted reason a satisfactory theory of things. Man is a hopeless enigma to himself, till he sees himself in the light of revelation as a fallen creature. The Fall alone explains the nobleness and the meanness of humanity. Christ is the only solution in which the baffled reason can rest. These are the two points on which Pascal's thought turns. Far from being able to sit in judgment upon the mysteries of the faith, reason is unable to solve its own contradictions without aid from a higher source.

HUME

Hume is the most illustrious and typical of modern sceptics. His scepticism is sometimes placed, as by Kant, in his distrust of our ability and right to pass beyond the empirical sphere. But it is essential to the sceptical position that reason be dethroned within experience as well as beyond it, and this is undoubtedly the result at which Hume arrives. The *Treatise* (1739–40) is a *reductio ad absurdum* of the principles of Lockianism, inasmuch as these principles, when consistently applied, leave the structure of experience entirely "loosened" (to use Hume's own expression), or cemented together only by the irrational force of custom. Hume's scepticism thus really arises from his thoroughgoing empiricism. Starting with "particular perceptions" or isolated ideas let in by the senses, he never advances beyond these "distinct existences." Each of them exists on its own account; it is what it is, but it contains no reference to anything beyond itself. The very notion of objectivity and truth therefore disappears. Hume's analysis of the conceptions of a permanent world and a permanent self reduces us to the sensationalistic relativism of the Greek Sophist, Protagoras. He expressly puts this forward in various passages as the conclusion to which reason conducts us. The fact that the conclusion is in "direct and total

opposition" to the apparent testimony of the senses is a fresh justification of philosophical scepticism. For, indeed, scepticism with regard to the senses is considered in the *Enquiry* (1748) to be sufficiently justified by the fact that they lead us to suppose "an external universe which depends not on our perception," whereas "This universal and primary opinion of all men is soon destroyed by the slightest philosophy." Scepticism with regard to reason, on the other hand, depends on an insight into the irrational character of the relation which we chiefly employ, viz., that of cause and effect. It is not a real relation in objects, but rather a mental habit of belief engendered by frequent repetition or custom. This point of view is applied in the *Treatise* universally. All real connection or relation, therefore, and with it all possibility of an objective system, disappears; it is, in fact, excluded by Hume from the outset, for "the mind never perceives any real connection among distinct existences."

KANT

The system of Kant, or rather that part of his system expounded in the *Critique of Pure Reason* (1781), though expressly distinguished by its author from scepticism, has been included by many writers in their survey of sceptical theories. The difference between Kant, with his system of pure reason, and any of the thinkers passed in review is obvious; and his limitation of reason to the sphere of experience suggests in itself the title of agnostic or positivist rather than that of sceptic. Yet, if we go a little deeper, there is substantial justification for the view which treats agnosticism of the Kantian type as essentially sceptical in its foundations and in its results. For criticism not only limits our knowledge to a certain sphere, but denies that our knowledge within that sphere is real; we never know things as they actually are, but only as they appear to us. This doctrine of relativity really involves a condemnation of our knowledge (and of all knowledge), because it fails to realize an impossible and self-contradictory ideal. The man who impeaches the knowing faculties because of the fact of relation which they involve, is pursuing the phantom of an apprehension which, as Lotze expresses it, does not apprehend things, but is itself things; he is desiring not to know but to be the things themselves. If this dream or prejudice be exploded, then the scepticism originating in it—and a large proportion of recent sceptical thought does so originate—loses its basis. The prejudice, however, which meets us in Kant is, in a somewhat different form, the same prejudice which is found in the "tropes" of antiquity—what Lotze calls the "inadmissible relation of the world of ideas to a foreign world of objects." For, as he rightly points out, whether we suppose idealism or realism to be true, in neither case do the things themselves pass into our knowledge. No standpoint is possible from which we could compare the world of knowledge with such an independent world of things, in order to judge of the conformity of the one to the other. But the abstract doubt "whether, after all, things may not be quite other in themselves than that which by the laws of our thought they necessarily appear" is a scepticism which, though admittedly irrefutable, is as certainly groundless. No arguments can be brought against it, simply because the scepticism rests on nothing more than the empty possibility of doubting. This holds true, even if we admit the "independent" existence of such a world of things. But the independence of things may with much greater reason be regarded as itself a fiction or prejudice. The real "objective" to which our thoughts must show conformity is not a world of things in themselves, but the system of things as it exists for a perfect intelligence. Scepticism is deprived of its persistent argument if it is seen that, while our individual experiences are to be judged by their coherence with the context of experience in general, experience as a whole does not admit of being judged by reference to anything beyond itself.

THE 19TH CENTURY

During the 19th century, the methods of measurement and enumeration, coming down from Newton and Leibniz, were applied in many spheres with such success that, by 1850, a new scepticism, in the shape of positivism unaware of its own dogmas, acquired vogue. This was the heyday of materialism. The natural universe, with "matter" as *substratum* came to be viewed as a given changeless system wherein everything followed from an irreversible cosmic order. The spiritual must be accounted merely a side-issue, devoid of intrinsic reality. On this scheme gravitation, electricity, magnetism and other forces were paraded as properties of "matter"—all else betrayed the taint of illusion or, to be plain, superstition. The hidden postulate—that nothing is valid save sense-perception—inevitably led to dogmatism. Hence types of scepticism arose successively, agnosticism being the earliest, while, very gradually during the final quarter of the 19th century, more rapidly during the first quarter of the 20th, the theological aspect of the issue fell in shadow, thanks to unprecedented extension of natural knowledge and profound socio-economic changes.

The Reign of Law.—The mechanical conception of nature ruled between 1850 and 1870. The atomic theory, reverting to implications as old as Democritus, the theorem of the conservation of energy when energy was accounted a purely mechanical principle, the early hypotheses of physiology after the enunciation of the cell-theory, and the doctrine of evolution thrust into physical categories, lent seeming authority to the uniformity of "matter" as the whole import of the uniformity of nature. The "reign of law," reducing all phenomena to motion, appeared to warrant an ultimate philosophy bound to oust "Romantic" sentimentalism. Experiential test had established calculable truths; therefore, it alone could guarantee the truth. In short, Hume's view, that nothing is valid save sense-perception, came to be identified with the system of actual science.

Agnosticism in Theology.—Meanwhile Protestant theology, notably in Germany, beset by opposition between inward faith and historical criticism, was fain to fall back upon abstract subjectivity. Nature, conceived as a vast automatic mechanism, betrays no spiritual purpose; and the corporate witness of the Christian consciousness down the ages, being deprived of divine intimation by positivist history, had become "naturalized" similarly. The contradiction between Reason and Faith seemed irremediable when Nature and the Church and the Scriptures could furnish no decisive guidance. Hence, relying upon a negative interpretation of Kant, Albrecht Ritschl (1822–88) and his disciples distinguished sharply between "scientific" and "religious" experience, denied theological validity to the former, and found the latter purely in the attitude of the believer to the object of his belief. This attitude is determined by the psychical facts of sin, recognition of forgiveness, and conviction of restoration of the will to goodness, which, taken together, furnish sufficient evidence of the historical person of Jesus as a divine revelation, and the necessary antecedent of a God Who can reconcile. Thus, no matter what natural science and "scientific" history may conclude, these "value-judgments" of inward consciousness remain quite unaffected. So far as the believer is concerned, there is neither reign of natural law nor immanent development within human history. "Things-in-themselves" being inscrutable, have no bearing upon individual conviction, which is a practical affair justified by results. "The redemption of man by the surrender of his own will to the will of the Whole" becomes irrelevant, because the Whole and its will have disappeared. So, as in ancient scepticism, man is the measure of all things, seeing that judgments of faith are "only intelligible as the expression of the personal self-certainty of the human spirit which is in some way morally determined." Religion is no theory, but a practice "utilized by the living person as a means to his own ends." In short, religion is conserved at the price of objective truth. Later developments seem to show that this position has not been maintained with its pristine rigour.

Current forms of scepticism bear intimate relation to discoveries in the natural sciences and psychology, to the perspective induced by the historical outlook, and to social displacements accompanied by the development of anti-intellectualism. A summary (and therefore partial) statement follows:—

Physiologism.—Things are external to us in space. Hence, the physiological conditions antecedent to perception interpose a veil between us and objects and direct knowledge is ruled out. Again,

the cerebro-spinal states on which perception depends may as well be effects of disturbances within the organism as of stimuli from without. Evidently, this view assumes the existence of objects out of relation to consciousness and also that one part of knowledge is valid, disclosing, as it does, reasons for the dubiety of perception.

Psychologism.—Granted that the mind is merely a "natural object," it is conditioned by time no less than by space. But reference to past time presupposes memory, and to future time anticipation. Psychologically, both are untrustworthy; therefore man is confined to the specious present. In any case, whatever may be said for knowledge derived from the past, the future baffles penetration; even "laws of nature" may alter or lapse, and it would seem to follow that all experiential conjunctions are casual. Scepticism of this kind involves the dogma that hypotheses as to uniformity are inadmissible, and that objective "fact," other minds included, is at best a perilous inference. It may be added that Behaviourism is dogmatic rather than sceptical, being a subtle recrudescence of materialism.

Historicism.—This is sometimes treated as if it were identical with naturalism; that is, given an evolving series, discovery of origins suffices for "explanation," not merely of "species," but also of "values" in the spiritual and social life. The underlying assumptions are too plain to require comment. Thus, in its sceptical drift, Historicism rather implies that, on review of the past all opinions and, equally, their practical consequences, in institutions, etc., can be shown to have been bemused by hopeless diversity of judgment. In particular, thinkers who profess to decide fundamentals, exhibit irremediable contradiction. It is absurd, then, to claim that ultimates are capable of settlement. This view involves a negative dogma, by denying the possibility of progressive insight—hypothesis can never rise to theory. The process of phenomena, each member its own witness, hides aught that may lie behind.

Pragmatism.—In so far as it embodies an emphatic protest against certain types of philosophy, pragmatism cannot be identified with scepticism off-hand. But, being a species of geneticism, it favours sceptical tendencies. "Logical forms and structures are distinctions within the process of reflective and experimental enquiry." If so, all "laws" must be judged evanescent. On this score, pragmatic geneticism and futurism are anti-intellectual. Notwithstanding, they embrace belief in the creative function of an evolutionary process (Bergson), and justify the voluntaristic creed of modernism (Blondel). Even so, the reason for the validity of the hypothesis is made secondary to other considerations. Consequences are good, because subserving happiness, etc., and not true, because in agreement with a *ratio essendi.* Hence the sceptical thrust. Truth is relative to individual activity which happens to be in continuous process of transmutation. Thus, truth can never be more than the best relevant or temporary adjustment; hence, all questions about the truth must be reckoned artificial. Coming in at the death, intellect can but offer bad reasons for manifest effects. Meantime, it were prudent, perhaps, to regard pragmatism rather as a search for a technique by a generation eager to formulate new values than as bare scepticism. Taken thus, it employs dogmas of its own—reality on the make in linear progress, for example. Nevertheless it is the symptomatic philosophy of a period of disintegration, often doubtful whether the "world-spirit" be for it or against it, and seeking a criterion in "social utility."

CONCLUSION

Of a scepticism which professes to doubt the validity of every reasoning process and every operation of all our faculties it is, of course, as impossible as it would be absurd to offer any refutation. This absolute scepticism, indeed, can hardly be regarded as more than empty words; the position which they would indicate is not one which has ever existed. In any case, such scepticism is at all times sufficiently refuted by the imperishable and justifiable trust of reason in itself. The real function of scepticism in the history of philosophy is relative to the dogmatism which it criticizes. And, as a matter of fact, it has been seen that many so-called sceptics were rather critics of the effete systems which they found cumbering the ground than actual doubters of the possibility of knowledge in general. And even when a thinker puts forward his doubt as absolute it does not follow that his successors are bound to regard it in the same light. The progress of thought may show it to be relative, as when the nerve of Hume's scepticism is shown to be his thoroughgoing empiricism, or when the scepticism of the *Critique of Pure Reason* is traced to the unwarrantable assumption of things-in-themselves. When the assumptions on which it rests are proved to be baseless, the particular scepticism is also overcome. In like manner, the apparent antinomies on which such a scepticism builds will be found to resolve themselves for a system based on a deeper insight into the nature of things. The serious thinker will always repeat the words of Kant that, in itself, scepticism is "not a permanent resting-place for human reason." Its justification is relative and its function transitional.

SCÈVE, MAURICE (1500?–1564), French poet, was born at Lyons, where his father practised law. Besides following his father's profession he was a painter, architect, musician, and poet. He was the centre of the Lyonnese group who elaborated the theory of spiritual love, derived partly from Plato and partly from Petrarch, which was enunciated in Antoine Héroet's *Parfaicte Amye.*

Scève's chief works are *Délie, objet de plus haulte vertu* (1544); two eclogues, *Arion* (1536) and *La Saulsaye* (1547), and *Le Microcosme* (1562), an encyclopaedic poem beginning with the fall of man. *Délie* (an anagram for *l'idée*) set the fashion of a series of poems addressed to a mistress real or imaginary, followed by Ronsard in *Cassandre* and by Du Bellay in *Olive.* For the Lyonnese school of which Scève was the leader *see* LABÉ, LOUISE.

See Pernetti, *Recherches pour servir à l'histoire de Lyon* (1757); E. Bourciez, *La Littérature polie et les moeurs de cour sous Henri II.* (1886); F. Brunetière, "Un Précurseur de la Pléiade, Maurice Scève," in his *Études critiques,* vol. vi. (1899).

SCHACHT, HJALMAR (1877–), German financier, was born at Tingleff, near Flensburg, on Jan. 22, 1877. After studying political economy, he became secretary of the *Handelsvertragsverein* (Trade Agreements League) 1901–03, and was then deputy director of the Dresden Bank until 1916. From 1916 to 1923 he was a member of the board of the Nationalbank für Deutschland, afterwards the Darmstädter und Nationalbank. He was appointed president of the German Reichsbank in Dec.

1923. In 1924 he collaborated in the conference of London and the deliberations of the Dawes Committee and in 1929 he was the chief German representative on the expert committee which sat in Paris to attempt the settlement of the reparations question. Dr. Schacht also established the Gold Bank of issue (*Goldnotenbank*).

SCHADOW, a family of German artists.

I. Johann Gottfried Schadow (1764–1850), sculptor, was born in Berlin, where his father was a poor tailor. His first teacher was an inferior sculptor, Tassaert, patronized by Frederick the Great, but with the aid of his father-in-law Schadow was able later to study in Rome. In 1788 he returned to Berlin to succeed Tassaert as court sculptor and secretary to the Academy. Over half a century he produced some two hundred works. His earlier work, including a portrait statue of Frederick playing the flute and the charming group of the crown-princess Louise and her sister, was notable for its directness and naturalness in an age of artificiality. For a long time Schadow stood out against the classicist movement, becoming engaged in a controversy with Goethe on the subject; but the forces against him were too strong, and his Rostock monument to Blücher, supervised by Goethe, represents the great field marshal in a lion's skin and toga after the affected manner of the day. He died in Berlin in 1850.

Two fine examples of his classical sculpture are the Quadriga on the Brandenburger Tor and the allegorical frieze on the façade of the Royal Mint in Berlin. Thirty church monuments and memorial works are enumerated. Besides the Blücher monument he executed one of Frederick the Great at Stettin and that of Luther at Wittenberg. His busts number over a hundred, and include 17 colossal heads in the Valhalla at Ratisbon. He also wrote treatises on the proportions of the human figure, on national physiognomy, etc.

II. His eldest son Rudolph Schadow (1786–1822), sculptor, was born in Rome and at first studied with his father in Berlin. In 1810 he went to Rome and was befriended by Canova and Thorwaldsen. He showed great versatility, producing now a figure of Paris, now a girl spinning, and, after becoming a convert to Roman Catholicism, statues of John the Baptist and of the Virgin and Child. In England he executed bas-reliefs for the duke of Devonshire and the marquis of Lansdowne. For the king of Prussia he modelled a colossal group of "Achilles with the body of Penthesilea." He died in Rome in 1822.

III. Friedrich Wilhelm Schadow (1789–1862), painter, was the second son of Johann Gottfried. He was born in Berlin on Dec. 6, 1789. In 1810 he went with his elder brother Rudolph to Rome, where he became a leading German pre-Raphaelite. With his friend Overbeck and others he also joined the Roman Catholic church. Together with Cornelius, Overbeck and Veit, Schadow received a commission from the Prussian consul, General Bartholdi, to decorate a room in his house on the Pincian Hill with frescoes of "Joseph and his Brethren," the two scenes executed by Schadow being the "Bloody Coat" and "Joseph in Prison." In 1819 Schadow became a professor in the Berlin Academy, and in 1826 was appointed director at Düsseldorf, where he entirely re-organized the Academy and made it a centre of Christian art to which students flocked from all sides. In 1859, after a reaction against Schadow's sacerdotal style had set in, the Naturalist party succeeded in deposing him. He died at Düsseldorf on March 19, 1862. His most important work is the "Wise and Foolish Virgins" (1842) at the Staedel Institute, Frankfurt.

SCHAFF, PHILIP (1819–1893), American theologian and church historian, was born at Chur, Switzerland, on Jan. 1, 1819. He was educated at the gymnasium of Stuttgart, and at the universities of Tübingen, Halle and Berlin, where he became *Privatdozent* in 1842. In 1843 he became professor of church history and biblical literature in the German Reformed Theological seminary of Mercersburg, Pennsylvania. On his journey he stayed six months in England and met Pusey and other Tractarians. His inaugural address on *The Principle of Protestantism,* delivered in German at Reading (Pa.), in 1844, and published in German and in an English version by J. W. Nevin (1845), by its Neander-like view that Romanism and Protestantism were only stages in the divinely appointed development of the Christian Church, caused him to be tried for heresy. Schaff's broad views strongly influenced the German Reformed Church. His *History of the Apostolic Church* (in German, 1851; in English, 1853) and his *History of the Christian Church* (1858–92) were standard works. In 1870 he became a professor at the Union Theological seminary, holding successively several different chairs till his resignation in the spring of 1893. He died in New York city on Oct. 20, 1893. The English Bible Revision committee in 1870 requested him to form a co-operating American committee, of which he became president in 1871. He also was a founder of the American Society of Church History (1888) and president until his death. He strove earnestly to promote Christian unity and union; his last labours being in behalf of the Parliament of Religions held at the Chicago World's Fair. He remains one of the foremost of American theological scholars, both through the quality and the remarkable quantity of his work. He edited the American translation and revision of Lange's *Bibelwerk* (1864–80), the great Schaff-Herzog *Encyclopaedia of Religious Knowledge* (1884); the first 7 volumes of the Nicene and Post-Nicene Church Fathers in English (1886–94); the *International Illustrated Commentary on the New Testament* (1879–82) and the *International Revision Commentary* (1881–84), as far as the Epistle to the Romans. His *Bibliotheca symbolica ecclesiae universalis: the Creeds of Christendom* (1877) was a pioneer work in English in the field of symbolics. He was the author also of literary essays, biographies and other works.

See his *Life* (1897) by his son, David Schley Schaff.

SCHAFFHAUSEN, the most northerly Swiss canton, lying almost wholly north of the Rhine, which, in part, separates it from the cantons of Zürich and Thurgau. On the other sides it is surrounded by Baden, portions of which separate the canton into three detached portions; the largest is the region near the chief town, Schaffhausen. Southwards, the small lowland isolated district of Rüdlingen and Buchberg was purchased in 1520, and Zürich, in 1798, ceded a slightly more extensive eastward tract around the old town of Stein. The territory contains two tiny Baden "enclaves," of which the village of Büsingen and the small tract of land surrounding it is the larger and more important. The total area of the canton is (1923–24 determinations) 115 sq.m., of which the high proportion of 95·3% are classed as "productive" (forests covering 45·5 sq.m., and vineyards 1·3 sq.m.). The dominant land feature is the plateau of Randen—Hohe Randen summit 2,998 ft., is on the northern boundary—sloping gently southwards to the Rhine and intersected by short glens such as Klettgau (west of Schaffhausen) which carry intermittent water torrents. The Rhine 1½ m. below the capital is a stream 370 ft. wide, interrupted by the famous falls (Laufen), which, though of small height (60 ft.), are of considerable grandeur; they are exploited for hydro-electric power. The capital is an important railway junction. It is on the main line from Constance to Basle which traverses the canton, and also has normal railway linkages with Friedrichshafen (Lake of Constance), and Zürich (2 lines). Schleitheim (north-west) is connected to it by a light railway. In 1920 the population was 50,428, of whom 48,258 were German-speaking, 1,611 were Italian-speaking and 339 were French-speaking, while 39,294 were Protestants, 10,768 Catholics and 51 Jews. The inhabitants are devoted chiefly to agriculture and to vine growing; its well managed forests are also a considerable source of revenue. The manufacture of watches and jewellery is also assuming considerable importance. Schaffhausen (pop. 21,650) is the only large town. Neuhausen (6,450) near the Rhine falls has an important aluminium works. There are six administrative districts containing 36 communes. The Cantonal Constitution dates from 1876. The legislature (*Grossrat*) is composed of 78 members elected (by the system of absolute majority) for four years in the proportion of one to every 600 residents. The executive (*Regierungsrat*) of five members is also elected for four years by a popular vote, as are the two members of the Federal *Ständerat* and the three members of the Federal *Nationalrat.* Since 1876, any 1,000 electors have the right of "initiative," both for legislative projects and for the revision of the Cantonal Constitution. Since 1895 the "obligatory referendum" for all legislative projects and financial resolutions has prevailed. Taxation is light, for the public cantonal property, *e.g.,* forests, is the most

considerable in Switzerland and the area is particularly prosperous.

The canton, admitted into the Confederation in 1501, arose from acquisitions made at various dates by the town; the chief of these were the outlying estates of the ecclesiastical foundations suppressed at the time of the Reformation. Of historical interest in this connection is the little town of Stein-am-Rhein (pop. 2,113) with its Benedictine monastery (1005–1526)—now restored to form a museum of antiquities—and Hohenklingen—the castle of the feudal lords of Stein—towering above it.

SCHAFFHAUSEN, Fr. *Schaffhouse,* the capital of the Swiss canton of that name, situated on rising ground above the right bank of the Rhine, and 31 m. by rail W. of Constance. In 1920 it had 20,064 inhabitants (18,872 German-speaking), while there were 14,023 Protestants, 5,811 Roman Catholics, and 39 Jews. The estimated population (1928) was 21,650. The spot is first mentioned in 1045, "Villa Scafhusun," while in 1050 we hear of the "ford" there across the Rhine.

About 1050 the counts founded here the Benedictine monastery of All Saints, which henceforth became the centre of the town. Perhaps as early as 1190, certainly in 1208, it was an imperial free city, while the first seal dates from 1253. The powers of the abbot were gradually limited and in 1277 the emperor Rudolf gave the town a charter of liberties. The Habsburgs held the town from 1330 to 1415, its freedom being finally purchased in 1418, while from 1411 the trade gilds ruled the town. In 1454 it made an alliance with six of the Swiss confederates, by whom it was received as an "ally," being finally admitted a full member in 1501. The Reformation was adopted in 1524, finally in 1529. The town suffered much in the Thirty Years' War from the passage of Swedish and Bavarian troops.

Schaffhausen is a city of contrasts, mediaeval architecture of the true Swabian type and modern manufactures mingling curiously together. The chief ancient building in the town is the *Münster* (now Protestant) of All Saints, formerly a Benedictine monastery. It was consecrated in 1052, and is a specimen of the sternest and plainest Romanesque. Close to it is deposited the famous 15th-century bell that suggested Schiller's *Song of the Bell* and the opening of Longfellow's *Golden Legend.* The castle of Unnoth, above the town, dates in its present form from the second half of the 16th century.

There are a number of factories in the town, while at Neuhausen, its suburb, are aluminium, as well as railway rolling stock works. Industrial development has been furthered by the works for the utilization of the forces in the Rhine, now the property of the town; since 1900 they have been worked by electricity.

BIBLIOGRAPHY.—E. Im-Thurn, *Der Kanton Schaffhausen* (St. Gall and Bern, 1840); F. L. Baumann, *Das Kloster Allerheiligen in Schaffhausen* (vol. iii. of the "Quellen z. Schweizer Geschichte") (Basle, 1881); *Beiträge z. vaterländisch. Geschichte* (5 parts, 1863–84). In 1901 there appeared at Schaffhausen two elaborate historical "Festschriften," one for the canton and one for the town.

SCHAFFNER, JAKOB (1875–   ), Swiss novelist and story-writer, was born at Basel on Feb. 14, 1874, was educated in a charity school, and worked as a shoemaker until his 30th year. He won the Schiller prize for his novel *Johannes* (1922). Schaffner is a master of the short story, as may be seen in *Die Goldene Fratze* (1912), *Verhängnisse* (1927), and *Föhnwind* (1928). He has also published an unconventional and lively *History of Switzerland* (1915), a volume advocating various political and social reforms, and a collection of poems (*Der Kreislauf;* 1927). Schaffner's style is marked by freshness, geniality, imagination and humour, often recalling Gottfried Keller (*q.v.*). He is, perhaps, at his best in dealing with the world of toil and machinery familiar to him from his own early experience.

SCHAPPE. A term denoting a particular type of yarn spun from "schappe" waste silk from which the natural gum, termed sericin has not been entirely removed or discharged either by "boiling-off" by the English system of "degumming" raw silk, or by the alternative Continental system of fermentation, known as "schapping." The waste silk so treated is soft and lustrous, with the fine silk filaments free from each other, yet retaining some of their natural gum. Schappe silk varies from a white to a bright yellow tone according to the amount of gum still present.

Schappe also denotes a particular type of silk fabric sold under that trade-name and produced from two-ply "schappe" spun silk yarn which, before bleaching, has a somewhat yellow tone owing to the presence of the natural gum. A schappe silk fabric is a fairly strong and firm texture of medium weight, woven on the principle of the plain calico weave, but having a slightly fine ribbed effect somewhat similar to that of a fine "poplin" (*q.v.*) texture but with the ribs or cords much less pronounced. This fine ribbed effect is developed by employing warp yarn of finer denier or counts than that of the weft, and also by inserting a greater number of warp threads than picks of weft, per inch, in the fabric. Thus, one example of "schappe" silk fabric contains 104 warp threads of 52's/2, and 72 picks of 40's/2 weft, per inch.

These denominations of yarn counts are equivalent to 52's and 40's counts of single cotton yarn respectively. They are produced by folding and doubling together two silk threads each of 50 denier silk (approximately) to produce the 52's/2 silk thread, and two threads each of 65 denier silk (approximately) to produce the 40's/2 silk thread. (H. N.)

SCHARLIEB, DAME MARY DACOMB (1845–   ), British surgeon, born in London on June 18, 1845, daughter of William Candler Bird. She was educated privately, and married a barrister practising in India. She entered the medical college at Madras, receiving its diploma in 1878, and afterwards studied at the London School of Medicine for Women. In 1883 she returned to Madras where she became lecturer in midwifery and gynaecology at the Medical College, and examiner at the university. In 1888 she took her London M.D. and from 1887 to 1902 was surgeon at the New Hospital for Woman, being senior surgeon from 1889. In 1887 she was appointed lecturer on forensic medicine to the Royal Free Hospital, in 1889 lecturer on midwifery, and in 1902 chief gynaecologist. She retired from these posts in 1909, in 1917 was made C.B.E., and in 1926 D.B.E. She was a member of the royal commission on Venereal Diseases (1913–16).

She wrote a number of works on medical subjects; her *Reminiscences* appeared in 1924.

SCHARNHORST, GERHARD JOHANN DAVID VON (1755–1813), Prussian general, was born at Bordenau near Hanover, on Nov. 12, 1755. In 1778 he received a commission in the Hanoverian service. He designed, and in part published, a *Handbuch für Offiziere in den anwendbaren Theilen der Kriegswissenschaften.* He also published in 1792 his *Militärische Taschenbuch für den Gebrauch im Felde.* His first campaign was that of 1793 in the Netherlands, in which he served under the duke of York with distinction. In 1794 he took part in the defence of Menin and commemorated the escape of the garrison in his *Vertheidigung der Stadt Menin* (Hanover, 1803), which, next to his paper *Die Ursachen des Glücks der Franzosen in Revolutionskrieg,* is his best-known work. Shortly after this he was promoted major and employed on the staff of the Hanoverian contingent.

In 1801 he entered the service of the king of Prussia, who gave him a patent of nobility, and the rank of lieutenant-colonel. Scharnhorst was employed at the War Academy of Berlin, where he had Clausewitz (*q.v.*) as one of his pupils, and he was the founder of the Berlin Military Society. In the mobilizations and precautionary measures of 1804 and 1805, and in the war of 1806, Scharnhorst was chief of the general staff (lieutenant-quartermaster) of the duke of Brunswick, and received a slight wound at Auerstedt. He attached himself to Blücher in the last stages of the disastrous campaign, was taken prisoner with him at the capitulation of Ratkau, and, being shortly exchanged, bore a prominent part in the leading of L'Estocq's Prussian corps which served with the Russians. For his services at Eylau, he received the order *pour le mérite.*

Educated in the traditions of the Seven Years' War, Scharnhorst had by degrees divested his mind of antiquated forms of war, and come to realise that a "national" army and a policy of fighting decisive battles alone responded to the political and strategical situation created by the French Revolution. The

steps by which he converted the professional long-service army of Prussia, wrecked at Jena, into the national army as we know it to-day, based on universal service, were slow and laboured. He was promoted major-general a few days after the peace of Tilsit, and placed as the head of a reform commission, to which were appointed Gneisenau, Grolman, Boyen and others. Stein himself became a member of the commission and secured for Scharnhorst free access to the king by causing him to be appointed aide-de-camp-general. But Napoleon's suspicions were quickly aroused, and the king had repeatedly to suspend or to cancel the reforms recommended. By direct application to Napoleon, Scharnhorst evaded the decree of Sept. 26, 1810, commanding all foreigners to leave the Prussian service forthwith, but when in 1811–1812 Prussia was forced into an alliance with France against Russia and despatched an auxiliary army to serve under Napoleon's orders, Scharnhorst left Berlin on unlimited leave of absence. In retirement he wrote his *Über die Wirkung des Feuergewehrs* (1813). But the retreat from Moscow at last sounded the call to arms for the new national army of Prussia. Scharnhorst was recalled to headquarters, and was made chief of staff to Blücher. The first battle, Lützen or Gross-Görschen, was a defeat, but a very different defeat from those which Napoleon had hitherto been accustomed to inflict. Scharnhorst was wounded, and died from the effects of his wound on June 8, at Prague, where he had been sent to negotiate with Schwarzenberg and Radetzky for the armed intervention of Austria.

See C. von Clausewitz, *Über das Leben und den Charakter des General v. Scharnhorst;* a life by M. Lehmann (Leipzig, 1886–88, an important work in two volumes); also Max Jähns, *Gesch. der Kriegswissenschaften,* iii. 2,154; Weise, *Scharnhorst und die Durchführung der allgemeinen Wehrpflicht* (1892); A. von Holleben, *Der Frühjahrsfeldzug, 1813* (1905).

SCHAUMBURG-LIPPE, a republic since November, 1918, and a constituent State of the German Republic. It consists of the western half of the old countship of Schaumburg, and is surrounded by Westphalia, Hanover and Hesse-Nassau. Area, 131 sq.m. Its northern extremity is occupied by a lake named the Steinhuder Meer. The southern part is hilly (Wesergebirge), but the remainder consists of a fertile plain. Besides husbandry, the inhabitants practise yarn-spinning and linen-weaving, and the coal-mines of the Bückeberg, on the south-eastern border, are very productive. The great bulk of the population is Lutheran. The capital is Bückeburg, and Stadthagen is the only other important town. The constitution dates from Feb. 24, 1922, but has since been amended. The Landtag consists of 15 members.

SCHEELE, KARL WILHELM (1742–1786), Swedish chemist, was born at Stralsund, the capital of Pomerania, which then belonged to Sweden, on Dec. 19, 1742. He studied the elements of chemistry during his apprenticeship to an apothecary in Gothenburg, with whom he stayed for eight years. In 1770 he settled at Uppsala, where he made the personal acquaintance of Bergman (*q.v.*). A friendship soon sprang up between the two men, and it has been said that Scheele was Bergman's greatest discovery. In 1775, the year in which he was elected into the Stockholm academy of sciences, he left Stockholm for Köping, a small place on Lake Malar, where he became proprietor of a pharmacy. He found time for an extraordinary amount of original research, and every year he published two or three papers, most of which contained some discovery or observation of importance. His unremitting work, it is said, especially at night, induced a rheumatic attack which brought about his death on May 19, 1786.

Scheele's record as a discoverer of new substances is probably unequalled, in spite of his poverty and lack of ordinary laboratory conveniences. His first paper was published in 1770 in conjunction with his friend Retzius; it dealt with the isolation of tartaric acid from cream of tartar. (*See* ANTIMONY.) The analysis of manganese dioxide in 1774 led him to the discovery of chlorine and baryta, to the description of various salts of manganese itself, including the manganates and permanganates, and to the explanation of its action in colouring and decolourizing glass. In 1775 he investigated arsenic acid and its reactions, discovering arsine and "Scheele's green" (copper arsenite). (*See* ARSENIC.) Papers, published in 1776 were concerned with quartz, alum and clay and with the analysis of *calculus vesicae* from which for the first time he obtained uric acid. In 1777 Scheele prepared sulphuretted hydrogen, and noted the chemical action of light on silver compounds and other substances. (*See* SULPHUR.) In 1778 he proposed a new method of making calomel and powder of algaroth, and he got molybdic acid from mineral *molybdaena nitens* which he carefully distinguished from ordinary molybdena (plumbago or black lead of commerce). In the following year he showed that plumbago consists essentially of carbon, and he published a record of estimations of the proportions of oxygen in the atmosphere, which he had carried on daily during the whole of 1778—three years before Cavendish. In 1780 he proved that the acidity of sour milk is due to what was afterwards called lactic acid; and by boiling milk sugar with nitric acid he obtained mucic acid.

His next discovery, in 1781, was in connection with the mineral scheelite (calcium tungstate), from which he obtained tungstic acid. In 1782 he published some experiments on the formation of ether, and in 1783 examined the properties of glycerine, which he had discovered seven years before. About the same time in the course of some work on Prussian blue he described the composition, properties and compounds of prussic acid, and even ascertained its smell and taste, quite unaware of its poisonous character. In the last years of his life he returned to the vegetable acids, and investigated citric, malic, oxalic and gallic acids (*qq.v.*). His only book, on *Air and Fire,* was published in 1777, but was written some years before. The manuscript was in the hands of the printers in 1775, and most of the experimental work for it was done before 1773. One of the chief observations recorded in it is that the atmosphere is composed of two gases—one which supports combustion and the other which prevents it. The former, "fire-air," or oxygen, he prepared from "acid of nitre," from saltpetre, from black oxide of manganese, from oxide of mercury and other substances, and there is little doubt but that he obtained the gas two years before Priestley. Owing to the delay in the publication of his results he is rarely given credit for this discovery. Scheele remained in favour of the phlogiston theory (*see* CHEMISTRY: *History of*) until his death; he apparently thought that hydrogen, which he had obtained by the action of certain acids on iron or zinc was pure *phlogiston.*

A list of Scheele's papers is given in Poggendorff's *Biographisch-litterarisches Handwörterbuch* (Leipzig, 1863). They were collected and published in French as *Mémoires de chymie* (Paris, 1785–88); in English as *Chemical Essays,* by Thomas Beddoes (1786); in Latin as *Opuscula,* translated by Schäfer, edited by Hebenstreit (Leipzig, 1788–89); and in German as Sämtliche Werke (ed. by Hermbstadt, 1793). The work on *Air and Fire* appeared in German at Leipzig and Uppsala in 1777, and again in 1782; in English (ed. by J. R. Forster 1780); and in French (ed. by Dietrich, 1781). *See* W. A. Tilden, *Famous Chemists* (1921).

SCHEELITE, a mineral consisting of calcium tungstate; $CaWO_4$. It was early known as "tungsten" (meaning in Swedish, "heavy stone"), and is the mineral in which K. W. Scheele discovered tungstic acid, hence the name scheelite. Well-developed crystals are not frequent; they usually have the form of acute tetragonal bipyramids, but compact and granular masses are much more abundant. The colour is usually yellowish white or brownish, the crystals sometimes transparent to translucent; the lustre vitreous to adamantine. The hardness is 4·5, the specific gravity 6·0. Molybdenum is usually present, replacing an equivalent amount of tungsten; and in a green variety known as "cuproscheelite" part of the calcium is replaced by copper.

Scheelite usually occurs with topaz, fluor, apatite, wolframite, etc., in tin-bearing veins, and wolfram is often more or less altered to scheelite. Good crystals come from Traversella in Piedmont; massive forms from Carrock Fell, Cumberland; the Riesengebirge in Germany and Czechoslovakia; and Corrèze, France. But the largest known deposits, of great commercial value as an ore of tungsten, are found in California, near Atolia and Randsburg, San Bernardino and Kern counties; and near Bishop, Inyo county: there tungsten-bearing granite magma has invaded highly calcareous rocks, so that scheelite is formed instead of wolfram.

SCHEER, REINHARD (1863–1928), German admiral, was born at Oberkirchen, Hesse-Nassau, on Sept. 30, 1863. After

serving in Cameroon and East Africa, in 1903 he was given command of the 1st torpedo division. In 1910 he became chief-of-staff of the High Sea Fleet under Von Holtzendorff, and in 1913 became commander of a battle squadron. At the outbreak of the World War he was stationed at Kiel with his squadron. Scheer introduced many important improvements in submarine tactics. In Jan. 1916 he was placed in command of the German High Sea Fleet, which he led at the battle of Jutland. On July 2, 1918, he succeeded Von Holtzendorff as chief of the Admiralty Staff. On Nov. 14, 1918, he was placed on the retired list, and took up residence in Weimar, where he died on Nov. 25, 1928. Scheer's account of the battle of Jutland appears in his book *Deutschlands Hochseeflotte im Weltkriege* (1920).

SCHEFFEL, JOSEPH VIKTOR VON (1826–1886), German poet and novelist, was born at Karlsruhe on Feb. 16, 1826. He studied at Munich, Heidelberg and Berlin, entered the State judicial service, and for four years (1848–52) held an official position at Säckingen. Here he wrote his poem *Der Trompeter von Säckingen* (1853), a romantic and humorous tale which immediately gained extraordinary popularity. It has reached more than 250 editions. In 1854 he quitted the Government service and settled at Heidelberg, with the intention of joining the teaching staff of the university. His studies were interrupted by eye-disease, and he went to live on the Lake of Constance. There he elaborated the plan of his famous historical romance *Ekkehard* (1857), the scene of which is laid in the monastery of St. Gall in the 10th century; (Eng. trans. by S. Delffs, Leipzig 1872). The first ideas for this work he got from the *Monumenta Germaniae*. In 1901 *Ekkehard* had reached the 179th edition. Scheffel next returned to Heidelberg, and published *Gaudeamus, Lieder aus dem Engeren und Weiteren* (1868), a collection of joyous and humorous songs, the matter for which is taken partly from German legends, partly from historical subjects. Scheffel was custodian (1857–59) of the library of Prince Egon von Fürstenberg at Donaueschingen; he eventually settled at Karlsruhe, in which city he died on April 9, 1886.

Scheffel's *Gesammelte Werke* have been published in 6 vols. (1907). *See* A. Ruhemann, *Joseph Victor von Scheffel* (1887); G. Zernin, *Erinnerungen an Joseph Victor von Scheffel* (1887); J. Prölss, *Scheffels Leben und Dichten* (1887); L. von Kobell, *Scheffel und seine Frau* (1901); E. Boerschel, *J. V. von Scheffel und Emma Heim* (1906).

SCHEFFER, ARY (1795–1858), French painter of Dutch extraction, was born at Dort on Feb. 10, 1795, the son of a painter of German origin. After his father's death his mother, also an artist, took him to Paris and placed him in the studio of Guérin. Scheffer had little sympathy with the direction given to the Romantic movement by its most conspicuous representatives, Delacroix or Géricault, and made various tentative efforts—"Gaston de Foix" (1824), "Suliot Women" (1827)—before he found his own path, which is essentially classicist. With charm and facility of composition, his colour was earthy, and his sentiment somewhat vapid. He turned to Byron and Goethe, selecting from Faust a long series of subjects which had an extraordinary vogue. Among his most notable works are the "St. Augustin and St. Monica" in the Louvre and the "Francesca da Rimini" in the Wallace collection. He died at Argenteuil on June 15, 1858.

See Vitet's notice (1861) prefixed to Bingham's publication of works of A. Scheffer; A. Etex, *Ary Scheffer* (1859); Mrs. Grote, *Life of A. Scheffer* (1860).

SCHEIDEMANN, PHILIPP (1865–), German politician, was born at Kassel July 26, 1865. In 1903 he entered the *Reichstag* as deputy for Kassel, and in the course of the World War became leader of the Majority Socialists. He voted for the government's war credits and supported its policy up to 1917, when he was associated with Erzberger in the "Peace Resolution" of July 19, 1917, which demanded "peace without annexation or indemnities." He was already exercising influence in German internal politics and was frequently consulted by Bethmann Hollweg. In June 1918 he became vice-president of the *Reichstag*, and on Oct. 3 Secretary of State without portfolio in Prince Max of Baden's Cabinet. On Nov. 9 Scheidemann proclaimed the German Republic from the buildings of the *Reichstag*. On Nov. 10 he was one of the three Majority Socialists who formed the first Provisional Government of the Republic. Although violently attacked by the Spartacists and Minority Socialists as a "counter revolutionary," he undoubtedly helped to save his country from bloodshed and anarchy, and on Feb. 8, 1919, was elected president of the first republican ministry of the *Reich* by the Constituent Assembly at Weimar. On June 20, 1919, he vehemently opposed signing the Treaty of Versailles and resigned when a majority of the Government decided to sign. He then resumed the leadership of the Majority Socialists in the National Assembly and subsequently in the republican *Reichstag*. His reminiscences in *Der Zusammenbruch* (1921) are supplemented by *The Making of New Germany* (1929). (*See* also GERMANY: *Political History*.)

SCHELDT (Fr. *Escaut*, Flem. *Schelde*), a river rising near Catelet in France, entering Belgium near Bleharies in Hainaut, and flowing past Tournai, Oudenarde, Ghent and Termonde till it reaches Antwerp. Some distance below Antwerp, in front of the island Beveland, where the river divides into two channels, respectively north and south of the island, both banks belong to Holland. Of the two channels named, the southern, De Hout, which reaches the sea at Flushing, is used for ocean commerce. The Scheldt has a length of 250 m., of which, by a skilful arrangement of locks, not less than 207 m. are navigable. Its breadth is 500 metres at Antwerp and 1,200 metres where it leaves Belgium. The principal tributaries are the Lys, the Dender and the Rupel. By the treaty of Munster in 1648 the Dutch obtained the right to close the Scheldt to navigation, and they clung tenaciously to it for over two centuries. In 1839 on the final dissolution of the kingdom of the Netherlands, Holland gave definite form to this right by fixing the toll, and by obtaining the assent of the powers to the arrangement which fettered the trade of Antwerp. In 1863 after long negotiations Belgium bought up this right—each of the powers interested in the trade contributing its quota—and the navigation of the Scheldt was then declared free. For the subsequent history of the Scheldt question *see* HOLLAND: *History* and BELGIUM: *History*.

SCHELLING, FRIEDRICH WILHELM JOSEPH VON (1775–1854), German philosopher, was born on Jan. 27, 1775 at Leonberg, a small town of Württemberg. He was educated at the cloister school of Bebenhausen, near Tübingen, where his father, an able Orientalist, was chaplain and professor, and entered the theological seminary at Tübingen at 16. Among his (elder) contemporaries were Hegel and Hölderlin. He shared in the revolutionary sentiments common among his fellow-students, and was suspected of being the author of a German version of the Marseillaise. In 1792 he graduated. Meanwhile he was a close student of Kant, Fichte and Spinoza, more especially of Fichte. Schelling had no sooner grasped the leading ideas of Fichte's amended form of the critical philosophy than he put together his impressions of it in his *Über die Möglichkeit einer Form der Philosophie überhaupt* (1794). The more elaborate work, *Vom Ich als Princip der Philosophie, oder über das Unbedingte im menschlichen Wissen* (1795), while remaining within the limits of the Fichtean idealism, exhibits a tendency to give the Fichtean method a more objective application and to amalgamate with it Spinoza's more realistic view.

After two years as tutor to two youths of noble family, Schelling was called as extraordinary professor of philosophy to Jena, the centre of the poets and philosophers of the Romantic School, in midsummer 1798. He had already contributed articles and reviews to the *Journal* of Fichte and Niethammer; had written the *Briefe über Dogmatismus und Kriticismus* (1796), a critique of the ultimate issues of the Kantian system, and *Neue Deduction des Naturrechts* (1797), which to some extent anticipated Fichte's treatment in the *Grundlage des Naturrechts*. His studies of physical science bore rapid fruit in the *Ideen zu einer Philosophie der Natur* (1797), and the treatise *Von der Weltseele* (1798). The philosophical renown of Jena was at its height during the years (1798–1803) of Schelling's residence. His intellectual sympathies united him closely with some of the most active literary tendencies of the time. With Goethe he was on excellent terms, but he was repelled by Schiller's less expansive disposition. In Schelling, essentially a self-conscious genius, eager and rash, yet with unde-

niable power, the Romanticists hailed a personality of the true Romantic type. With August Wilhelm Schlegel and his wife Caroline, herself the embodiment of the Romantic spirit, Schelling's relations were intimate, and a marriage between Schelling and Caroline's young daughter, Auguste Böhmer, was vaguely contemplated by both. Auguste's death in 1800 (due partly to Schelling's rash confidence in his medical knowledge) drew Schelling and Caroline together, and Schlegel having removed to Berlin, a divorce was, apparently with his consent, arranged. On June 2, 1803, Schelling and Caroline were married, and with the marriage Schelling's life at Jena came to an end.

From 1803 to 1806 Schelling was professor at the new university of Würzburg. During this time he broke both with Fichte and Hegel. He embroiled himself with his colleagues and also with the Government. In Munich, to which he removed in 1806, he found a quiet residence. A position as State official, at first as associate of the academy of sciences and secretary of the academy of arts, afterwards as secretary of the philosophical section of the academy of sciences, gave him ease and leisure. Without resigning his official position he lectured for a short time at Stuttgart, and during seven years at Erlangen (1820–27). In 1809 Caroline died, and three years later Schelling married one of her closest friends, Pauline Gotter, in whom he found a faithful companion.

During the long stay at Munich (1806–41) Schelling's literary activity seemed gradually to come to a standstill. The "Aphorisms on Naturphilosophie" contained in the *Jahrbücher der Medicin als Wissenschaft* (1806–08) are for the most part extracts from the Würzburg lectures; and the *Denkmal der Schrift von den göttlichen Dingen des Herrn Jacobi* was drawn forth by the special incident of Jacobi's work. The only writing of significance is the "Philosophische Untersuchungen über das Wesen der menschlichen Freiheit," which appeared in the *Philosophische Schriften*, vol. i. (1809), and which carries out, with increasing tendency to mysticism, the thoughts of the previous work, *Philosophie und Religion.* In 1815 appeared the tract *Über die Gottheiten zu Samothrake,* ostensibly a portion of a great work, *Die Weltalter,* frequently announced as ready for publication, of which no great part was ever written. The dominance of Hegel in the German schools appears to have silenced Schelling. It was only in 1834, after the death of Hegel, that, in a preface to a translation by H. Beckers of a work by Cousin, he expressed in writing the antagonism in which he stood to the Hegelian and to his own earlier conceptions of philosophy. The antagonism certainly was not new; it was evidenced in the Erlangen lectures on the history of philosophy (*Sämt. Werke,* x. 124–125) of 1822, and Schelling had already begun the treatment of mythology and religion which in his view constituted the true positive complement to the negative of logical or speculative philosophy. The writings of Strauss, Feuerbach and other members of the Hegelian Left had alarmed the religious element. Frederick William IV. invited him to Berlin in 1841, and made him Prussian privy councillor and member of the Berlin Academy, in the hope that he would lecture at the university and counteract the Hegelians. But these were too strongly entrenched. In 1845 he ceased to lecture. No authentic information as to the nature of the new positive philosophy was obtained till after his death (at Bad Ragaz, on Aug. 20, 1854), when his sons began the issue of his collected writings with the four volumes of Berlin lectures: vol. i. *Introduction to the Philosophy of Mythology* (1856); ii. *Philosophy of Mythology* (1857); iii. and iv. *Philosophy of Revelation* (1858).

Schelling indicated the turning points of his philosophical career as follows:—(1) the transition from Fichte's method to the more objective conception of nature—the advance, in other words, to *Naturphilosophie;* (2) the definite formulation of that which implicitly, as Schelling claims, was involved in the idea of *Naturphilosophie,* viz., the thought of the identical, indifferent, absolute substratum of both nature and spirit, the advance of *Identitätsphilosophie;* (3) the opposition of negative and positive philosophy, an opposition which is the theme of the Berlin lectures, though its germs may be traced back to 1804. Only what falls under the first and second of the divisions so indicated can be said to have discharged a function in developing philosophy; only so much constitutes Schelling's philosophy proper.

Nature and spirit, *Naturphilosophie* and *Transcendentalphilosophie,* stand as two relatively complete, but complementary parts of the whole. Schelling, who sought the reconciliation of differences moved towards the conception of the uniting basis of which nature and spirit are manifestations, forms or consequences. For this common basis, however, he found at first only the negative expression of indifference. The identity, the absolute, which underlay all difference, all the relative, is to be characterized simply as *neutrum,* as absolute undifferentiated self-equivalence. Spinoza appeared to Schelling as the thinker whose form of presentation came nearest to his new problem. The *Darstellung meines Systems,* and the more expanded and more careful treatment contained in the lectures on *System der gesammten Philosophie und der Naturphilosophie insbesondere* given in Würzburg, 1804 (published in the *Sämtliche Werke,* vol. vi. pp. 131–576), are thoroughly Spinozistic in form, and to a large extent in substance. They are not without value, indeed, as extended commentary on Spinoza. But Schelling does not succeed in bringing his conceptions of nature and spirit into any vital connection with the primal identity, the absolute indifference of reason. No true solution could be achieved by resort to the mere absence of distinguishing, differencing feature. The absolute was left with no other function than that of removing all the differences on which thought turns. The criticisms of Fichte, and more particularly of Hegel (in the "Vorrede" to the *Phänomenologie des Geistes*), point to the fatal defect in the conception of the absolute as mere featureless identity.

In all his later writings Schelling strove to amend the conception of absolute reason as the ultimate ground of reality. He sought to give to this absolute a *character,* to make of it something more than empty sameness, and to clear up the relation in which the actuality or apparent actuality of nature and spirit stood to the ultimate real. He had already (in the *System der ges. Phil.*) sought an amalgamation of the Spinozistic conception of substance with the Platonic view of an ideal realm. Things—nature and spirit—have an actual being. They exist not merely as logical consequence or development of the absolute, but have a stubbornness of being in them. The actuality of things is a defection from the absolute, and their existence compels a reconsideration of our conception of God. There must be recognized in God as a completed actuality, a dim, obscure ground or basis, which can only be described as not yet being, but as containing in itself the impulse to externalization, to existence. It is through this ground of Being in God Himself that we must find explanation of that independence which things assert over against God. From this position Schelling was led on to the further statements that not in the rational conception of God is an explanation of existence to be found, but that God is to be conceived as act, as will, as something over and above the rational conception of the Divine. Hence the stress laid on will as the realizing factor, in opposition to thought, a view in which Schelling is a precursor of Schopenhauer and Von Hartmann, and on the ground of which he has been recognized by the latter as the reconciler of idealism and realism. Finally, then, there emerges the opposition of negative, *i.e.,* merely rational philosophy, and positive, of which the content is the real evolution of the divine as it has taken place in fact and in history, and as it is recorded in the varied mythologies and religions of mankind. Not much satisfaction can be felt with the exposition of either as it appears in the volumes of Berlin lectures.

Bibliography.—Schelling's works were collected and published by his sons, in 14 vols. (1856–61). The individual works appeared as follows:— *Über die Möglichkeit einer Form der Philosophie überhaupt* (Tübingen, 1794); *Ideen zu einer Philosophie der Natur* (Leipzig, 1797, ed. 1803); *Von der Weltseele* (Hamburg, 1798), 3rd ed., 1809); *Erster Entwurf eines Systems der Naturphilosophie* (Jena, 1799); *Einleitung zu seinem Entwurf der Naturphilosophie* (*ib.*, 1799); *System des transcendentalen Idealismus* (Tübingen, 1800); *Bruno, oder über das göttliche und natürliche Prinzip der Dinge* (1802, ed., 1843); *Vorlesungen über die Methode des akademischen Studiums* (Tübingen, 1803, ed. Braun, 1907); *Über das Verhältniss der bildenden Künste zu der Natur* (Munich, 1807); *Über die Gottheiten von Samothrake* (Stuttgart, 1815). His Munich lectures were published by A. Drews (Leipzig, 1902). For the life good materials are to be found in

Aus Schelling's Leben in Briefen (3 vols., 1869–70), containing a sketch by his son. The biography in Kuno Fischer's *Gesch. der neueren Philosophie,* vol. vii. (3rd ed., 1902) is complete and admirable. *See* further *Schelling als Persönlichkeit. Briefe, Reden, Aufsätze,* ed. Otto Braun (1908), who also wrote *Schellings geistige Wandlungen in den Jahren 1800–1810* (1906); Rosenkranz, *Schelling* (1843); L. Noack, *Schelling und die Philosophie der Romantik* (2 vols., 1859); G. A. C. Frantz, *Schelling's Positive Philosophie* (3 vols., 1879–80); Watson, *Schelling's Transcendental Idealism* (1882); Groos, *Die reine Vernunftwissenschaft. Systematische Darstellung von Schellings . . . Philosophie* (1889); E. von Hartmann, *Schelling's philos. System* (1897); Delbos, *De posteriore Schellingii philosophia quatenus Hegelianae doctrinae adversatur* (1902); Koeber, *Die Grundprinzipien der Schellingschen Naturphilosophie* (1882); G. (R. A.; X.)

SCHENECTADY (skĕ-nek′tạ-dĭ), a city of New York, U.S.A., the county seat of Schenectady county; 16 m. N.W. of Albany, on the Mohawk river. It has an airport, and is served by the Delaware and Hudson, the New York Central, the West Shore and electric railways. Pop. (1920) 88,723 (23% foreign-born white, over half from Italy, Poland and Germany); and 95,692 in 1930. The city has a fine site of 10·34 sq.m., 230 ft. above sea-level, in a beautiful and fertile region. It is a place of much historic interest, and has many examples of quaint Dutch colonial and early American architecture. St. George's Episcopalian church was built in 1762. The fine "Great Western Gateway" bridge (opened 1926) connects the highways east and south of the river with those north and west. A wide crosstown boulevard has been constructed (completed 1924) over the abandoned bed of the Erie canal. Union college was incorporated in 1795. The chapel was built in 1924 by public subscription as a memorial to the Union boys who died in the World War. The assessed valuation of property for 1927 was $191,642,280.

According to tradition Schenectady stands on the site of the chief village of the Mohawk Indians, and its name is of Indian origin. In 1661 Arendt Van Corlaer (or Curler), a cousin of the patroon Killian Van Rensselaer and manager of his manor, with 14 other residents of Rensselaerwyck, bought a tract here from the Indians, established a settlement, and in 1670 extended their territory to embrace about 128 square miles. The price was "600 hands of good Whyte Wampum, six Koates of Duffels, 30 Barres of Lead, and nine Bagges of Powder." Many of the early settlers were well-to-do and brought their slaves with them. For many years the settlement was reputed the richest in the colony. In 1690 (Feb. 9) a force of French and Indians surprised the village, burning it, killing 60 of the inhabitants and carrying 30 into captivity. About 1700 there was an influx of English settlers. Schenectady was chartered as a borough in 1765 and as a city in 1798. From the close of the Revolution to the opening of the Erie canal (1825) it was a lively river port, and boat-building was one of its chief industries. Railways to Albany and to Saratoga (the first in the State) were opened in 1831 and 1832. The manufacture of locomotives began in 1848. In 1850 the population was 8,921; in 1880 it was 13,655. Rapid development dates from the establishment in 1886 of the Edison Machine Works, which became a unit of the Edison General Electric Company in 1889 and the largest plant of the General Electric Company on its organization in 1892. The General Electric Company has here its general offices, research laboratories, broadcasting station (WGY) and largest manufacturing works, covering 645 ac. and comprising 350 buildings with 6,500,000 sq.ft. of floor space. The list of distinguished scientists who have been connected with the Schenectady plant includes W. R. Whitney, Irving Langmuir (*q.v.*), W. D. Coolidge and C. P. Steinmetz (*q.v.*). From 19,902 in 1890 the population of the city grew to 72,826 in 1910. The value of its manufactures in 1927 was $99,402,269.

SCHERER, EDMOND HENRI ADOLPHE (1815–1889), French theologian, critic and politician, was born in Paris on April 8, 1815. After a course of legal studies he spent several years in theological study at Strasbourg, where he graduated doctor in theology in 1843, and was ordained. He held a theological chair in a Protestant seminary at Geneva for a brief period, but developed liberal opinions on religious matters, and eventually settled in Paris as a journalist. He at once attracted attention by brilliant critical work, at first chiefly on great foreign writers, contributed to the *Revue des deux mondes.* He was elected municipal councillor at Versailles in 1870, deputy to the National Assembly for the department of Seine-et-Oise in 1871 and senator in 1875. He supported the Republican party. Scherer was for many years one of the ablest contributors to *Le Temps.* He was a frequent visitor to England, and took a lively interest in English politics and literature. He died at Versailles on March 16, 1889.

Among his works are: *Études critiques sur la littérature contemporaine* (1863–89), *Études critiques de littérature* (1876), *Diderot* (1880), *La Démocratie et la France* (1883), *Études sur la littérature au XVIIIe siècle* (1891).

SCHERER, WILHELM (1841–1886), German philologist and historian of literature, was born at Schönborn in Lower Austria on April 26, 1841. He studied at Vienna and afterwards at the university under the Germanist, Karl Viktor Müllenhoff (1818–84), and became *Privatdozent* for German language and literature in the university in 1864, and in 1868 professor. He was subsequently professor at Strasbourg (1872) and Berlin (1877). He died at Berlin on Aug. 6, 1886.

His first great work was *Zur Geschichte der deutschen Sprache* (1868, 3rd. ed., 1890), a history of the German language with special reference to phonetic laws. Scherer's best-known work is his history of German literature, *Geschichte der deutschen Literatur* (1883; 10th ed., 1905; Eng. trans. by Mrs. F. C. Conybeare, 1883; new ed. 1906).

See V. Basch, *Wilhelm Scherer et la philologie allemande* (1889), and the article by Eduard Schröder in *Allgemeine deutsche Biographie.*

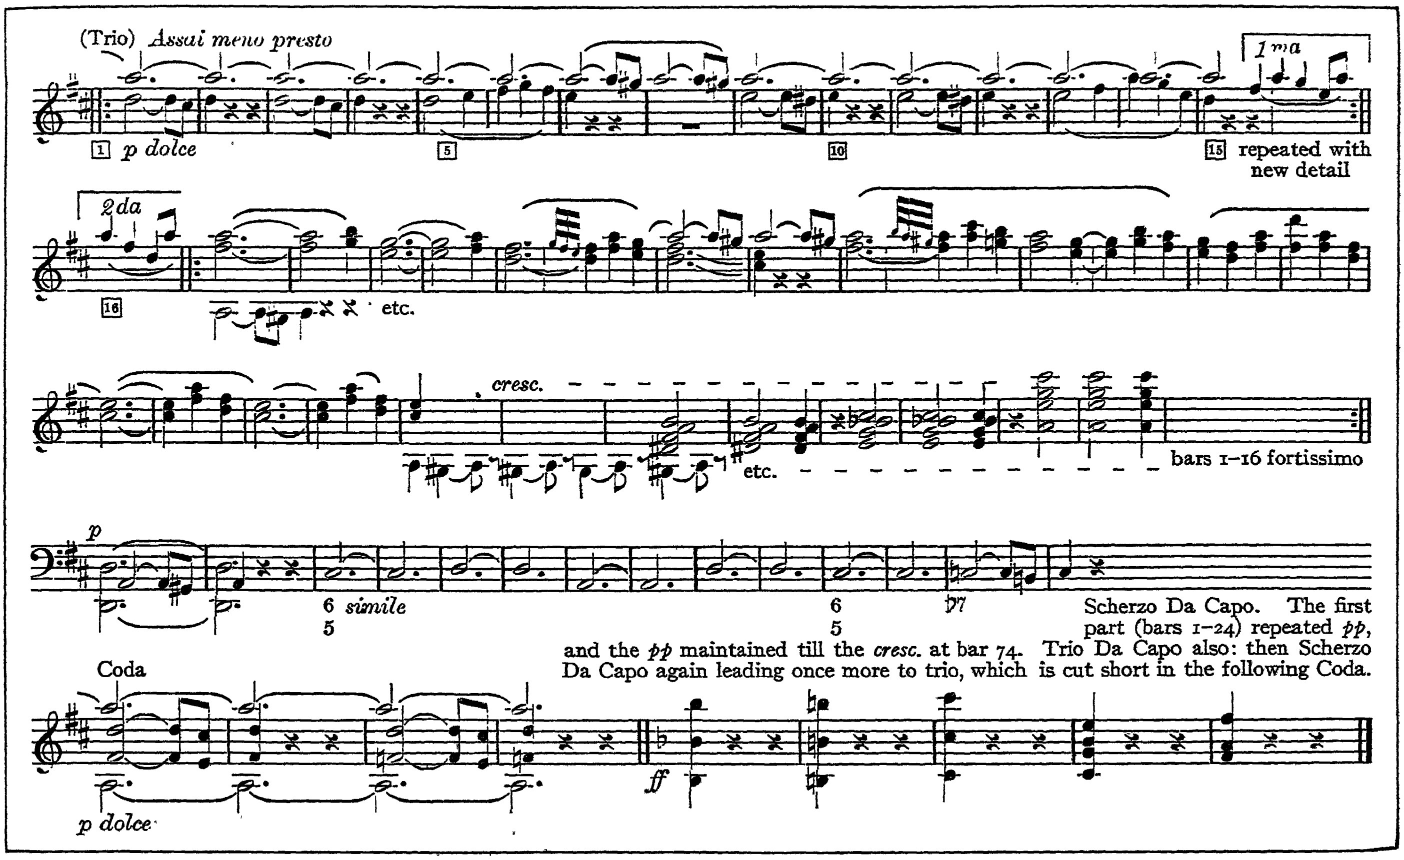
SCHERZO (Italian for "a joke"); in music, a quick movement evolved from the minuet and used in the position thereof in the sonata forms (*q.v.*). The term is also used as a mere character name. Haydn first used it and its adverb scherzando, for the middle movement of an early sonata in C sharp minor, and afterwards in place of the minuet in the set of six quartets known sometimes as "Gli Scherzi," and sometimes as the "Russian quartets" (op. 33). He never used the term again, though his later minuets are often in a very rapid *tempo* and sometimes on a larger scale than any of the earlier scherzos of Beethoven. Haydn wished to see the minuet made more worthy of its position in large sonata works; but he did not live to appreciate (though he might possibly have heard) the fully-developed scherzos of his pupil, Beethoven.

The formal essence of the minuet and trio lies in their combination of melodic forms with an exact *da capo* of the minuet after the trio. No other movement in the sonata has leisure for so purely decorative a symmetry. Beethoven's typical scherzos purposely exaggerate this quality. He does not follow Mozart's example of minuets with two trios, for the style of his mature scherzos is so continuous that a second trio would give it an elaborate *rondo* character unlike that of a dance-movement. But after Beethoven's scherzo has run through the stages of scherzo, trio and scherzo *da capo,* it goes through the same trio and *da capo* again; and then tries to do so a third time, as if it could not find a way out; so that it has to be abruptly stopped. Modern players and listeners are impatient of these grotesque repetitions; but the art-form is true to its own nature, and we should be the better for leisure to understand it. Apart from the wonderful little A flat bagatelle—No. 7 of the set written at the age of 15 and published (presumably with extensive revision) as op. 33—Beethoven first used the double repetition in his 4th symphony (with a shortening of the last *da capo*); and his last example is in the C sharp minor quartet (op. 131).

The scherzo of the 9th symphony is so enormous that its main body differs from a complete first movement of a sonata only in its uniformity of texture and its incessant onrush, which not even the startling measured pauses and the changes from 4-bar to 3-bar

Outline of SCHERZO of Beethoven's 7th Symphony.

(The phrasing given here is the most natural; but any phrasing whatever will prove that the themes change their accents in the course of the movement.)



rhythm can really interrupt. Beethoven directs as many repetitions of its subsections as possible, and his coda consists of an attempt to begin the trio again, dramatically cut short. The scherzo of the C minor symphony was originally meant to go twice round; and a certain pair of superfluous bars, which caused controversy for 30 years after Beethoven's death, were due simply to traces of the difference between the *prima volta* and *seconda volta* being left in the score.

Beethoven does not use the title of scherzo unless the music is humorous. Thus in the sonata in E flat (op. 31, No. 3) it is applied to a sonata-form lively movement which is technically the slow movement, while the following slow minuet is the dance-movement. The second movement of the F major quartet (op. 59, No. 1) is a unique example of scherzo-style in a most elaborate sonata-form.

Perhaps this gigantic movement may have been the inspiring source of the Mendelssohnian scherzo, one of the most distinct new types of movement since Beethoven, and quite independent of the notion of an alternating trio. The scherzos in Mendelssohn's *Midsummer Night's Dream* music, in the Scotch symphony and in the string quartets in E minor and E flat major (op. 44, Nos. 2 and 3) are splendid examples. Even Berlioz shows their influence in the "Queen Mab" scherzo of his *Roméo et Juliette*.

Of Brahms' scherzos there are several distinct types, ranging from a quiet allegretto and trio in melodic forms to the sonata-form *Presto giocoso* of the 4th symphony, which within seven minutes accomplishes the most powerful scherzo since Beethoven. Every degree of lyric beauty and dramatic passion is comprised in the various movements that Brahms puts into the position of scherzo in his sonata works.

Chopin produced a new type of independent scherzo; obviously inspired by Beethoven, but with a slightly macabre tendency of his own, except in the very diffuse and light 4th scherzo. The majority of classical scherzos are in a quick triple time with only one countable beat to a bar; and this custom is the last vestige of the derivation of the scherzo from the minuet.

Of modern scherzos there is nothing specific to be said; the term still applies to lively intermediate movements in cyclic instrumental works, and is otherwise a mere character-name.

(D. F. T.)

SCHEVENINGEN (Schā′nĭng-ẹn), fishing port and watering-place, Holland, on the North sea, province of South Holland, about 2 m. N. of The Hague, of which it is now a suburb. It is situated in the dunes at the extremity of the woods which separate it from The Hague. The development of Scheveningen as a fashionable seaside resort dates from modern times, but the fishing village is of ancient origin and once stood farther seaward. To prevent coast erosion a stone wall was built along the sea front in 1896–1900, and below this lies the fine sandy beach stretching for miles on either side. The first bathing establishment here dates from 1818, and was also the first in Holland. There is a large harbour for the fishing fleet.

SCHIAPARELLI, GIOVANNI VIRGINIO (1835–1910), Italian astronomer and senator of the kingdom of Italy, was born on March 14, 1835, at Savigliano in Piedmont. He entered Turin university in 1850, and graduated in 1854. Two years later he went to Berlin to study astronomy under Encke, and in 1859 was appointed assistant observer at Pulkova, a post which he resigned in 1860 for a similar one at Brera, Milan. On the death of Francesco Carlini (b. 1783) in 1862, Schiaparelli succeeded to the directorship, which he held until 1900. He died at Milan on July 4, 1910.

Schiaparelli possessed exceptional powers as an observer—his first discovery was of the asteroid Hesperia in 1861—and his considerable mathematical ability is shown in his papers. In 1866 he showed the connection between meteor streams and cometary orbits, giving, in particular, the identity of the orbits of the Perseids and Comet III., 1862, and of the Leonids and Comet I., 1866. These discoveries were subsequently amplified in his *Le Stelle cadenti* (1873) and in his *Norme per le osservazioni delle stelle cadenti dei bolidi* (1896). He observed double stars, and the results of his measures are published in 2 vols., the first containing those made between 1875–85, and the second those between

1886–1900. He made extensive studies of Mercury, Venus and Mars. In 1877 he observed on Mars the peculiar markings, which he called *canali,* the nature and origin of which is still controversial. (*See* MARS.) From his observations of Mercury and Venus he concluded that these planets rotated on their axes in the same time as they revolved about the sun. On his retirement he turned to the astronomy of the Hebrews and Babylonians; his earlier results are given in his *L' Astronomia nell' antico Testamento* (1903), which has been translated into English and German, whilst later ones are to be found in various journals, the last being in *Scientia* (1908).

SCHICHAU, FERDINAND (1814–1896), German engineer and shipbuilder, was born at Elbing, the son of a smith and ironworker, on Jan. 30, 1814. He started works of his own at Elbing in 1834, and was soon employing some 8,000 men. He began by making steam engines, hydraulic presses and industrial machinery, and, by concerning himself with canal work and river or coast improvement, came to the designing and construction of dredgers, in which he was the pioneer (1841), and finally to the building of ships.

His "Borussia," in 1855, was the first screw-vessel constructed in Germany. Schichau began to specialize in building torpedo-boats and destroyers (at first for the Russian Government) at an early date. From 1873 he had the co-operation of Carl H. Ziese, who married his daughter. Ziese introduced compound engines into the first vessels built by Schichau for the German navy, the gunboats "Habicht" and "Möwe," launched in 1879, and also designed in 1881 the first triple-expansion machinery constructed on the continent, supplying these engines to the torpedo-boats built by Schichau for the German navy in 1884, the first of some 160 that by the year 1909 were provided by the Elbing yards. Torpedo-boats were also built for China, Austria and Italy. Meanwhile Elbing had become insufficient for the increased output demanded. In 1889 Schichau established a floating dock and repairing shops at Pillau, and soon afterwards, by arrangement with the Government, started a large yard at Danzig. He died on Jan. 23, 1896.

SCHICKELE, RENÉ (1883–), Alsatian writer, was born in Oberehnheim, Alsace, Aug. 4, 1883. He was educated in Zabern and Strasburg, and afterwards lived in Paris and Berlin. His first works were poetic; they include the volumes *Sommernächte* (1902), *Der Ritt ums Leben* (1906), *Mein Herz mein Land* (1915). His first prose work was *Der Fremde* (1907). He has also written dramas, which are of less importance; but *Hans im Schnakenloch* (1916) was performed in both Paris and Berlin during the War. Schickele is essentially an Alsatian in both style and thought. He blends in his work, which unites warmth with strength in a remarkable degree, the essence of the Germanic and the Latin cultures. His life has been largely a revolt against the crushing of Alsace's individuality by either German or French. Before the World War he was in revolt against Germany. During the War, against which he protested strongly, he lived in Switzerland; but later he made his home in Germany, in the Black Forest. The most remarkable novels of his maturity are *Wir wollen nicht sterben* (1922), *Maria Capponi* (1925, English trans. 1928), and *Blick auf die Vogesen* (1927).

SCHIEDAM, a town and river port of Holland, in the province of South Holland, on the Schie, near its confluence with the Maas, and a junction station 3 m. W. of Rotterdam by rail. Pop. (1927), 43,263. The public buildings of interest are the Groote or Janskerk, the old Roman Catholic church, the synagogue, the town hall, the exchange, the concert-hall and a ruined castle. Schiedam is famous as the seat of a great gin manufacture, which, carried on in more than three hundred distilleries, gives employment besides to malt-factories, cooperages and cork-cutting establishments, and supplies sufficient yeast to form an important article of export.

SCHIFF, JACOB HENRY (1847–1920), American banker and philanthropist, was born at Frankfort-on-Main, Germany, Jan. 10, 1847. He studied in the schools of Frankfurt and for a time worked in a bank. In 1865 he went to New York city and organized the brokerage firm of Budge, Schiff and Co. In 1875 he was taken into the firm of Kuhn, Loeb and Co., and, on Loeb's retirement in 1885, took his place. In 1897 his house assisted E. H. Harriman in reorganizing the Union Pacific Railway, and in 1901 aided him in his struggle with James J. Hill and J. P. Morgan for the control of the Northern Pacific Railway. In his later years he gave much personal attention to charities. He was a founder and president of the Montefiore Home for chronic invalids, New York city. In 1903 he presented a Semitic museum building to Harvard university. He died in New York city Sept. 25, 1920.

SCHILL, FERDINAND BAPTISTA VON (1776–1809), Prussian soldier, was born in Saxony. Entering the Prussian cavalry at the age of twelve, he was still a subaltern of dragoons when he was wounded at the battle of Auerstädt. At Kolberg he played a very prominent part in the celebrated siege of 1807. After the peace of Tilsit he was given the command of a hussar regiment. In 1809 the political situation in Europe appeared to Schill to favour an attempt to liberate his country from the French domination. Leading out his regiment from Berlin under pretext of manoeuvres, he raised the standard of revolt, and marched for the Elbe. At Dodendorf (May 5, 1809) he had a brush with the Magdeburg garrison, but was soon driven northwards, where he hoped to find British support. With little more than his original force Schill was surrounded by 5,000 Danish and Dutch troops in the neighbourhood of Wismar. He escaped by hard fighting (action of Damgarten, May 24) to Stralsund. The Danes and Dutch soon hemmed him in, and by sheer numbers overwhelmed the defenders (May 31). Schill himself was killed.

See L. K. C. von Liliencron, *Schilliana* (2 vols., 1810); Haken, *Ferdinand von Schill* (Leipzig, 1824); Bärsch, *Ferdinand von Schill's Zug und Tod* (Leipzig, 1860), and *F. von Schill, ein Charakterbild* (Potsdam, 1860); Francke, *Aus Stralsunds Franzosenzeit* (1890).

SCHILLER, JOHANN CHRISTOPH FRIEDRICH VON (1759–1805), German poet, dramatist and philosopher, was born at Marbach on the Neckar, on Nov. 10, 1759. His father, Johann Kaspar (1723–96), was an army-surgeon, and the vicissitudes of his profession entailed a constant change of residence; but at Lorch and at Ludwigsburg, where the family was settled for longer periods, the child was able to receive a regular education. In 1773 the duke Karl Eugen of Württemberg claimed young Schiller as a pupil of his military school at the "Solitude" near Ludwigsburg, where he was obliged to devote himself to law. On the removal of the school in 1775 to Stuttgart, he was, however, allowed to take up medicine. The strict military discipline of the school lay heavily on Schiller, and intensified the spirit of rebellion, which burst out in the young poet's first tragedy. In 1776 some specimens of Schiller's lyric poetry had appeared in a magazine, and in 1777–78 he completed his drama, *Die Räuber.* In 1780 he left the academy qualified to practise as a surgeon, and was at once appointed by the duke as doctor to a regiment garrisoned in Stuttgart. His discontent found vent in the passionate lyrics of this period. Meanwhile *Die Räuber,* which Schiller had been obliged to publish at his own expense, appeared in 1781 and made an impression on his contemporaries hardly less deep than Goethe's *Götz von Berlichingen,* eight years before. The strength of this remarkable tragedy lay, in spite of its inflated tone and exaggerated characterization, in the sure dramatic instinct with which it is constructed and the directness with which it gives voice to the most pregnant ideas of the time. In this respect, Schiller's *Räuber* is one of the most vital German dramas of the 18th century. In January 1782 it was performed in the Court and National Theatre of Mannheim, Schiller himself having stolen secretly away from Stuttgart in order to be present. The success encouraged him to begin a new tragedy, *Die Verschwörung des Fiesco zu Genua,* and he edited a lyric *Anthologie auf das Jahr 1782,* to which he was himself the chief contributor. A second surreptitious visit to Mannheim came, however, to the ears of the duke; he had Schiller put under a fortnight's arrest, and forbade him to write any more "comedies" or to hold intercourse with any one outside Württemberg. Schiller resolved on flight, and took advantage of some court festivities in Sept. 1782 to put his plan into execution. He hoped in the first instance for material support from the theatre in

Mannheim and its intendant, W. H. von Dalberg; but nothing but rebuffs and disappointments were in store for him. He did not even feel secure against extradition in Mannheim, and after several weeks spent mainly in the village of Oggersheim, where his third drama, *Kabale und Liebe,* was in great part written, he found a refuge at Bauerbach in Thuringia, in the house of Frau von Wolzogen, the mother of one of his former schoolmates. Here *Kabale und Liebe* was finished and *Don Carlos* begun. In July 1783 he received a definite appointment for a year as "theatre poet" in Mannheim, and here both *Fiesco* and *Kabale und Liebe* were performed in 1784. In the latter play Schiller's powers as a realistic portrayer of people and conditions familiar to him are seen to best advantage. Although Schiller failed to win an established position in Mannheim, he added to his literary reputation by the publication of the beginning of *Don Carlos* (in blank verse) in his journal, *Die rheinische Thalia* (1785). He had also the opportunity of reading the first act of the new tragedy before the duke of Weimar at Darmstadt in Dec. 1784.

In April 1785 Schiller accepted the invitation of four unknown friends—C. G. Körner, L. F. Huber, and their *fiancées* Minna and Dora Stock—with whom he had corresponded, to pay a visit to Leipzig. He spent a happy summer mainly at Gohlis, near Leipzig, his jubilant mood being reflected in the *Ode an die Freude;* and in September of the same year he followed his new friend Körner to Dresden. As Körner's guest in Dresden and at Loschwitz on the Elbe, Schiller completed *Don Carlos,* wrote the dramatic tale, *Der Verbrecher aus verlorener Ehre* (1786), and the unfinished novel, *Der Geisterseher* (1789). Körner's interest in philosophy also induced Schiller to turn his attention to such studies, the first results of which he published in the *Philosophische Briefe* (1786). *Don Carlos,* meanwhile, appeared in 1787, and added to Schiller's reputation as a poet. It was unfortunate, however, that in seeking a model for this higher type of tragedy he turned rather to the classic theatre of France than to the English drama.

A new chapter in Schiller's life opened with his visit to Weimar in July 1787. Goethe was then in Italy, and the duke of Weimar was absent; but the poet was kindly received by Herder and Wieland. Not very long afterwards he made the acquaintance at Rudolstadt of the family von Lengefeld, the younger daughter of which subsequently became his wife. Meanwhile the preparation for *Don Carlos* had interested Schiller in history, and in 1788 he published the first volume of his chief historical work, *Geschichte des Abfalls der vereinigten Niederlande von der spanischen Regierung.* It obtained for him, on the recommendation of Goethe, a professorship in the university of Jena, and in Nov. 1789 he delivered his inaugural lecture. Schiller's other historical writings comprise a *Sammlung historischer Memoires* and *Geschichte des dreissigjährigen Krieges* (1791–93). The latter is written for a wider public than his first history, but the narrative is dramatic and vivid and the portraiture is sympathetic.

Before, however, this work was finished, Schiller had turned from history to philosophy. A year after his marriage he had been stricken down by severe illness, from the effects of which he was never completely to recover; financial cares followed, which were relieved unexpectedly by the generosity of the hereditary prince of Holstein-Augustenburg, who conferred upon him a pension of 1,000 talers a year for three years. Schiller devoted the leisure of these years to the study of philosophy. In the summer of 1790 he had lectured in Jena on the aesthetics of tragedy, and in the following year he studied carefully Kant's *Kritik der Urteilskraft,* which had just appeared and appealed powerfully to Schiller's mind. The influence of these studies is to be seen in several essays, as well as in his correspondence with his friend Körner. Here Schiller arrives at his definition of beauty, as "Freiheit in der Erscheinung," which marked the beginning of a new stage in the history of German aesthetic theory. *Über Anmut und Würde,* published in 1793, was a further contribution to the elucidation and widening of Kant's theories; and in the eloquent *Briefe über die ästhetische Erziehung des Menschen* (1795), Schiller proceeded to apply his new standpoint to the problems of social and individual life. These remarkable letters were published in *Die Horen,* a new journal, founded in 1794, which was the occasion for his gaining the friendship of Goethe. An immediate outcome of the new friendship was Schiller's admirable treatise, *Über naive und sentimentalische Dichtung* (1795–96). Here Schiller applied his aesthetic theories to that branch of art which was most peculiarly his own, the art of poetry; it is an attempt to classify literature in accordance with an a priori philosophic theory of "ancient" and "modern," "classic" and "romantic," "naïve" and "sentimental"; and it sprang from the need Schiller himself felt of justifying his own "sentimental" and "modern" genius beside the "naïve" and "classic" tranquillity of Goethe's.

For Schiller himself this was the bridge that led back from philosophy to poetry. Under Goethe's stimulus he won fresh laurels in that domain of philosophical lyric which he had opened with *Die Künstler;* and in *Das Ideal und das Leben, Die Macht des Gesanges, Würde der Frauen,* and *Der Spaziergang,* he produced masterpieces of reflective poetry. These poems appeared in the *Musenalmanach,* a new publication which Schiller began in 1796. Here were also published the *Xenien* (1797), a collection of distichs by Goethe and Schiller, in which the two friends avenged themselves on their critics. The *Almanach* of the following year was even more noteworthy, for it contained a number of Schiller's most popular ballads, *Der Ring des Polykrates, Der Handschuh, Ritter Toggenburg, Der Taucher, Die Kraniche des Ibykus* and *Der Gang nach dem Eisenhammer; Der Kampf mit dem Drachen* following in 1799, and *Das Lied von der Glocke* in 1800. As a ballad poet, Schiller's popularity has been hardly less great than as a dramatist; his bold and simple outlines, his terse dramatic characterization appealed directly to the popular mind. The supreme achievement of the last period of Schiller's life was the series of master dramas which he gave to the world between 1799 and 1804. Just as *Don Carlos* had led him to the study of Dutch history, so now his occupation with the history of the Thirty Years' War supplied him with the theme of his trilogy of *Wallenstein* (1798–99). The plan of *Wallenstein* was of long standing, and it was only towards the end, when Schiller realized the impossibility of saying all he had to say within five acts, that he decided to divide it into three parts, a descriptive prologue, *Wallensteins Lager,* and the two dramas *Die Piccolomini* and *Wallensteins Tod.* Without entirely breaking with the classic method he had adopted in *Don Carlos, Wallenstein* shows how much Schiller's art had benefited by his study of Greek tragedy; the fatalism of his hero is a masterly application of an antique motive to a modern theme. The success of *Wallenstein,* with which Schiller passed at once into the front rank of European dramatists, was so encouraging that the poet resolved to devote himself with redoubled ardour to dramatic poetry. Towards the end of 1799 he took up his residence permanently in Weimar, not only to be near his friend, but also that he might have the advantage of visiting regularly the theatre of which Goethe was director.

Wallenstein was followed in 1800 by *Maria Stuart,* a tragedy, which, in spite of its great popularity in and outside of Germany, is not one of his best. Finer in every way is the "romantic tragedy," *Die Jungfrau von Orleans* (1801). The resplendent mediaeval colouring of the subject, the heroic character of Joan of Arc, gave Schiller an admirable opportunity for the display of his rich imagination and rhetorical gifts; and by an ingenious alteration of the historical tradition he was able to make the drama a vehicle for his own moral idealism. Between this drama and its successor, *Die Braut von Messina,* Schiller translated and adapted to his classic ideals Shakespeare's *Macbeth* (1801) and Gozzi's *Turandot* (1802). With *Die Braut von Messina* (1803) he experimented with a tragedy on purely Greek lines, this drama being as close an approximation to ancient tragedy as its mediaeval and Christian *milieu* permitted. The introduction of a chorus detracted from the value of the tragedy for the theatre, but it appealed particularly to Schiller's genius. In the poet's last completed drama, *Wilhelm Tell* (1804), he once more, as in *Wallenstein,* chose a historical subject involving wide issues. *Wilhelm Tell* is the drama of the Swiss people; its subject is less the personal fate of its hero than the struggle of a nation to free itself from tyranny. It was an attempt to win for the German drama a new field, to

widen the domain of dramatic poetry. Besides writing *Tell*, Schiller had found time in 1803 and 1804 to translate two French comedies by Picard, and to prepare a German version of Racine's *Phèdre*; and in the last months of his life he began a new tragedy, *Demetrius*, which gave promise of being another step forward in his poetic achievement. But *Demetrius* remains a fragment of hardly two acts.

Schiller died at Weimar on May 9, 1805. His last years were darkened by constant ill-health; and indeed it is marvellous that he was able to achieve so much. A visit to Leipzig in 1801, and to Berlin in 1804, were the chief outward events of his later years. He was ennobled in 1802. Schiller's art, with its broad, clear lines, its unambiguous moral issues, and its enthusiastic optimism, has appealed with peculiar force to the German people, especially in periods of political despondency. But since the re-establishment of the German empire in 1871 there has been a certain waning of his popularity, the Germans of to-day realizing that Goethe more fully represents the aspirations of the nation. In point of fact, Schiller's genius lacks that universality which characterizes Goethe's; as a dramatist, a philosopher, an historian, and a lyric poet, he was the exponent of ideas which belong essentially to the Europe of the period before the French revolution.

BIBLIOGRAPHY.—The first edition of Schiller's *Sämtliche Werke* appeared in 1812–15 in 12 vols. Of the countless subsequent editions mention need only be made here of the *Historisch-kritische Ausgabe* by K. Goedeke (15 vols., 1867-76). Good modern editions are the *Säkularausgabe*, edited by E. von der Hellen and others (17 vols., 1904–05) and that edited by O. Güntter and G. Witkowsky (20 vols., 1904–11). A critical edition of Schiller's *Briefe* was published by F. Jonas (7 vols. 1892–96).

The chief biographies of Schiller are the following: T. Carlyle, *Life of Friedrich Schiller* (1824, German translation with an introduction by Goethe, 1830); E. Palleske, *Schillers Leben und Werke* (1858–59, 14th ed. 1894, Eng. trans. 1885); H. Viehoff, *Schillers Leben* (1875, new ed. 1888); J. Sime, *Schiller* (1882); R. Weltrich, *F. Schiller* (vol. i., 1890); O. Brahm, *Schiller* (vols. i. ii., 1888–92); J. Minor, *Schiller, sein Leben und seine Werke* (vols. i.–ii., 1890); O. Harnack, *Schiller* (1898, 2nd ed. 1905); C. Thomas, *Life and Works of Schiller* (1901); K. Berger, *Schiller* (1905–09: 9th ed., 1917); E. Kühnemann, *Schiller* (1905: Eng. transl., 1912). *See* further: V. Basch, *La Poétique de Schiller* (1902); L. Bellermann, *Schillers Dramen: Beiträge zu ihrem Verständnis* (2 vols., 1888–91; 4th ed., 1908); A. Köster, *Schiller als Dramaturg* (1891); K. Fischer, *Schiller-Schriften* (1891–92); J. W. Braun, *Schiller im Urteile seiner Zeitgenossen* (3 vols., 1882); J. G. Robertson, *Schiller after a Century* (1905); Schiller's *Gespräche*, ed. by J. Petersen (1911); M. Hecker and J. Petersen, *Schillers Persönlichkeit*, 3 vols. (1907–09); A. Ludwig, *Schiller und Die Deutsche Nachwelt* (1909). (J. G. R.)

SCHILTBERGER, JOHANN or **HANS** (1381–1440?), German traveller and writer, was born of a noble family in 1381, probably at Hollern near Lohof, half way between Munich and Freising. In 1394 he joined the suite of Lienhart Richartinger, and went off to fight under Sigismund, king of Hungary (afterwards emperor), against the Turks on the Hungarian frontier. At the battle of Nicopolis (Sept. 28, 1396) he was wounded and taken prisoner; Sultan Bayezid I. (*Ilderim*) then took him into his service as a runner (1396–1402). During this time he accompanied Ottoman troops to Asia Minor and Egypt. On Bayezid's overthrow at Angora (July 20, 1402), Schiltberger passed into the service of Bayezid's conqueror Timur: he now visited Samarkand, Armenia and Georgia. After Timur's death (Feb. 17, 1405) his German runner became a slave of various successors. He next accompanied Chekre, a Tatar prince living in Abu Bekr's horde, on an excursion to Siberia, of which name Schiltberger gives us the first clear mention in west European literature. He followed Chekre in his attack on the Old Bulgaria of the middle Volga. Wanderings in south-east Russia; visits to Sarai, the old capital of the Kipchak Khanate on the lower Volga and to Azov or Tana, still a trading centre for Venetian and Genoese merchants; travels in the Crimea, Circassia, Abkhasia and Mingrelia; and finally escape (from the neighbourhood of Batum) followed; he lay hid at Constantinople for a time, then returned to his Bavarian home (1427) by way of Kilia, Akkerman, Lemberg, Cracow, Breslau and Meissen. After his return he became a chamberlain of Duke Albert III.

Schiltberger's *Reisebuch* contains not only a record of his own experiences and a sketch of various chapters of contemporary Eastern history, but also an account of countries and their manners and customs. First come the lands "this side" of Danube, where he had travelled; next follow those between the Danube and the sea, which had now fallen under the Turk; then the Ottoman dominions in Asia; last come the regions from Trebizond to Russia and from Egypt to India. Schiltberger is perhaps the first writer of Western Christendom to give the true burial place of Mohammed at Medina; he contributed to fix Prester John, at the close of the middle ages, in Abyssinia.

Four mss. of the *Reisebuch* exist: (1) at Donaueschingen in the Fürstenberg library, No. 481; (2) at Heidelberg, university library, 216; (3) at Nuremberg, city library, 34; (4) at St. Gall, monast. library, 628 (all of 15th century, the last fragmentary). The work was first edited at Augsburg, *c.* 1460; four other editions appeared in the 15th century, and six in the 16th; in the 19th the best were K. F. Neumann's (Munich, 1859), P. Bruun's (Odessa, 1866, with Russian commentary, in the *Records of the Imperial University of New Russia*, vol. i.), and V. Langmantel's (Tübingen, 1885); "Hans Schiltbergers Reisebuch," in the 172nd volume of the *Bibliothek des literärischen Vereins in Stuttgart*. *See* also the English (Hakluyt Society) version, *The Bondage and Travels of Johann Schiltberger . . .*, trans. by Buchan Telfer with notes by P. Bruun (1879); C. R. Beazley, *Dawn of Modern Geography* (1897, etc.) iii. 356–378, 550.

SCHINZNACH, a small spa in the canton of Aargau (Switzerland). It is situated 3 m. from Brugg, in the lower valley of the river Aar, at the south-west foot of the small but steep, well-wooded hill mass of Wülpelsburg (1,683 ft. altitude). The village (1,165 ft. alt.; pop. *c.* 1,200) is famed for its strongly sulphurous and saline medicinal springs (90°–95° F) and, during the period May to September, annually, it is much patronized, principally by French visitors. Other popular spas, such as Müllingen and Birmenstorf, lying eastward in the valley of the river Reuss, are in its immediate vicinity. The Wülpelsburg is crowned by the ruins of an 11th century castle. Tradition claims that the count of Altenburg discovered his strayed hawk (Ger. *habicht*) on the hill summit, and the naturally defended site resulted in its selection for the erection of the Castle of Habichtsburg—the first important stronghold of the subsequently famous Habsburg dynasty of Austria.

SCHISM, a division, especially used of a formal separation from a church or religious body; a sect, or church formed by such separation. The dispute which led to the separation of the Latin and Greek Churches is known as the "Great Schism." *See* HERESY and for the "Great Schism" *see* PAPACY and CHURCH HISTORY.

SCHISTOSOMIASIS: *see* BILHARZIASIS.

SCHISTS, in petrology, metamorphic rocks which have a fissile character (Gr. σχίζειν, to split); in all there is at least one mineral which crystallizes in platy forms (*e.g.* mica, talc, chlorite, haematite), or in long blades or fibres (anthophyllite, tremolite, actinolite, tourmaline), and, when these have a well marked parallel arrangement in definite bands or folia, the rock will break far more easily along the bands than across them. The platy minerals have a perfect cleavage parallel to their flat surfaces, while the fibrous often have two or more cleavages following their long axes; hence a schistose rock may split not only by separation of the mineral plates from one another but also by cleavage of the parallel minerals through their substance.

Schists in the common acceptance of the term are completely recrystallized rocks; fissile slates, shales or sandstones, in which the sedimentary structures are little modified by recrystallization, are not included in this group by English petrologists, though the French *schistes* and the German *Schiefer* are used to designate also rocks of these types. The differences between schists and gneisses are that the latter have less highly developed foliation, are, as a rule, more coarse-grained, and contain far more quartz and felspar—two minerals which rarely assume platy or acicular forms, and hence do not lead to fissility in the rocks in which they are important constituents. Schists, as a rule, are found in regions composed mainly of metamorphic rocks, *e.g.*, the Central Alps, Himalayas and other mountain ranges, Saxony, Scandinavia, the Highlands of Scotland and N.-W. Ireland. They are typical products of "regional" metamorphism, and are in most cases

older than the fossiliferous sedimentary rocks. Transitions between schists and normal igneous or sedimentary rocks are often found. The Silurian mica-schists of Bergen are fossiliferous; in the Alps it is believed that even Mesozoic rocks pass laterally into mica-schists and calc-schists. These changes have probably been produced by the operation of heat, pressure and folding. Igneous rocks also may be converted readily into schists (*e.g.*, serpentine into talc-schist, dolerite into hornblende-schist) by the same agencies.

There are two great groups, viz., schists derived from (*a*) sedimentary and (*b*) igneous rocks, or, as they have been called, the "paraschists" and the "orthoschists." The first is the more important and includes some of the commonest metamorphic rocks. In the paraschists, though fossils are exceedingly rare, sedimentary structures such as bedding and the alternation of laminae of fine and coarse deposit may frequently be preserved; the foliation is often parallel to the bedding, but may cross it obliquely or at right angles, or the bedding may be folded and contorted while the foliation maintains a nearly uniform orientation. When the foliation is undulose or sinuous the rocks are said to be crumpled, and have wavy splitting surfaces instead of nearly plane ones. The development of foliation in shaly rocks is undoubtedly closely akin to the production of cleavage in slates.

The sedimentary schists or paraschists have three great subdivisions, the mica-schists (*q.v.*) and chlorite-schists (which correspond in a general way to shales or clay rocks) the calc-schists (impure limestones) and the quartz-schists (metamorphosed sandstones). The chlorite-schists are often of igneous derivation, such as ash-beds or fine lavas which have been metamorphosed. Many of them contain large octahedra of magnetite. Others are probably sedimentary rocks, especially those which contain much muscovite. Calc-schists are usually argillaceous limestones in which a large development of biotite or phlogopite has occasioned foliation. Often they contain quartz and felspar, sometimes pyroxene, amphibole, garnet or epidote. Pure limestones do not frequently take on schistose facies. The quartz-schists consist of quartz and white mica, and are intimately related to quartzites. Many of them have been originally micaceous or felspathic sandstones. We may mention also graphitic-schists containing dark scaly graphite (often altered forms of carbonaceous shales), and haematite-schists which may represent beds of ironstone.

The orthoschists are white mica-schists produced by the shearing of acid rocks, such as felsite and porphyry. Some of the "porphyroids" which have grains of quartz and felspar in a finely schistose micaceous matrix are intermediate between porphyries and mica-schists of this group. Still more numerous are orthoschists of hornblendic character (hornblende-schists) consisting of green hornblende with often felspar, quartz and sphene (also rutile, garnet, epidote or zoisite, biotite and iron oxides). These are modified forms of basic rocks such as basalt and dolerite. Every transition can be found between perfectly normal ophitic dolerites and typical hornblende-schists, and occasionally the same dike or sill will provide specimens of all the connecting stages. A few hornblende-schists are metamorphosed gabbros; others have developed from dikes or sills of lamprophyre. Under extreme crushing these basic rocks may be converted into dark biotite-schists, or greenish chlorite-schists. Tremolite-schist and anthophyllite-schist are in nearly all cases the representatives of the ultra-basic igneous rocks such as peridotite in regions of high metamorphism. Talc-schists are of the same category. They are soft and lustrous, with a peculiarly smooth feel. They are also known as the products of metamorphism of siliceous dolomitic limestones.

SCHLEGEL, AUGUST WILHELM VON (1767–1845), German poet, translator and critic, was born on Sept. 8, 1767, at Hanover, where his father, Johann Adolf Schlegel (1721–1793), was a Lutheran pastor. He was educated at the Hanover gymnasium and at the university of Göttingen. Having spent some years as a tutor in the house of a banker at Amsterdam, he went to Jena, where, in 1796, he married Karoline Michaelis, the widow of the district medical officer Böhmer and in 1798 was appointed extraordinary professor. Here he began his translation of Shakespeare, which was ultimately completed, under the superintendence of Ludwig Tieck, by Tieck's daughter Dorothea and Graf W. H. Baudissin. This rendering is one of the best poetical translations in German, or indeed in any language. At Jena Schlegel contributed to Schiller's periodicals the *Horen* and the *Musenalmanach;* and with his brother Friedrich he conducted the *Athenaeum,* the organ of the Romantic school. He also published a volume of poems, and carried on a rather bitter controversy with Kotzebue. The brothers were the leaders of the new Romantic criticism. A volume of their joint essays appeared in 1801 under the title *Charakteristiken und Kritiken.* In 1802 Schlegel went to Berlin, where he lectured on art and literature; and in the following year he published *Ion*, a tragedy in Euripidean style, which gave rise to a suggestive discussion on the principles of dramatic poetry. This was followed by *Spanisches Theater* (2 vols., 1803–1809), in which he presented admirable translations of five of Calderon's plays; and in another volume, *Blumensträusse italienischer, spanischer und portuguesischer Poesie* (1804), he gave translations of Spanish, Portuguese and Italian lyrics. In 1807 he attracted much attention in France by an essay in the French language, *Comparaison entre la Phèdre de Racine et celle d'Euripide,* in which he attacked French classicism from the standpoint of the Romantic school. His lectures on dramatic art and literature (*Über dramatische Kunst und Literatur,* 1809–1811), which have been translated into most European languages, were delivered at Vienna in 1808.

Meanwhile, after a divorce from his wife Karoline, in 1804, he travelled in France, Germany, Italy and other countries with Madame de Staël, who owed to him many of the ideas which she embodied in her work, *De l'Allemagne.* In 1813 he acted as secretary to the crown prince of Sweden. Schlegel was made a professor of literature at the university of Bonn in 1818, and during the remainder of his life occupied himself chiefly with oriental studies, although he continued to lecture on art and literature, and in 1828 he issued two volumes of critical writings (*Kritische Schriften*). In 1823–1830 he published the journal *Indische Bibliothek* (3 vols.) and edited (1823) the *Bhagavad-Gīta* with a Latin translation, and (1829) the *Rāmāyana.* These works mark the beginning of Sanskrit scholarship in Germany. After the death of Madame de Staël Schlegel married (1818) a daughter of Professor Paulus of Heidelberg; but this union was dissolved in 1821. He died at Bonn on May 12, 1845. As an original poet Schlegel is unimportant, but as a poetical translator he has rarely been excelled.

In 1846–47 Schlegel's *Sämtliche Werke* were issued in twelve volumes by E. Böcking. There are also editions by the same editor of his *Œuvres écrites en français* (3 vols., 1846), and of his *Opuscula Latine scripta* (1848). Schlegel's Shakespeare translations have been often reprinted; the edition of 1871–72 was revised with Schlegel's mss. by M. Bernays. *See* M. Bernays, *Zur Entstehungsgeschichte des Schlegelschen Shakespeare* (1872); R. Genée, *Schlegel und Shakespeare* (1903); J. Koerner, *Romantiker und Klassiker. Die Brüder Schlegel in ihren Beziehungen zu Schiller und Goethe* (1924); Schlegel's Berlin lectures of 1801–04 were reprinted from ms. notes by J. Minor (1884). A selection of the writings of both A. W. and Friedrich Schlegel, edited by O. F. Walzel, will be found in Kürschner's *Deutsche Nationalliteratur,* 143 (1892). *See* especially R. Haym, *Romantische Schule,* and the article in the *Allg. deutsche Biographie* by F. Muncker.

SCHLEGEL, FRIEDRICH VON (1772–1829), German poet, critic and scholar, was the younger brother of August Wilhelm von Schlegel. He was born at Hanover on March 10, 1772. He studied law at Göttingen and Leipzig, but ultimately devoted himself entirely to literary studies. He published in 1797 the important book *Die Griechen und Römer*, which was followed by the suggestive *Geschichte der Poesie der Griechen und Römer* (1798). Goethe and Schiller looked to the Greeks for form and objectivity; Schlegel's hellenism was romantic and lyrical. At Jena, where he lectured as a *Privatdozent* at the university, he contributed to the *Athenäum* the aphorisms and essays in which the principles of the Romantic school are most definitely stated. This journal formed the centre for the first group of romanticists at Jena. Here also he wrote *Lucinde* (1799), an unfinished romance, which is interesting as an attempt to transfer to practical ethics the Romantic demand for complete individual freedom, and *Alarcos*, a

tragedy (1802) in which, without much success, he combined romantic and classical elements. In 1802 he went to Paris, where he edited the review *Europa* (1803), lectured on philosophy and carried on oriental studies, some results of which he embodied in *Über die Sprache und Weisheit der Indier* (1808).

In the same year in which this work appeared, he and his wife Dorothea (1763–1839), a daughter of Moses Mendelssohn, joined the Roman Catholic Church, and from this time he became more and more opposed to the principles of political and religious freedom. In 1809 he was appointed imperial court secretary at the headquarters of the archduke Charles at Vienna; later he was councillor of legation in the Austrian embassy at the Frankfort diet, but in 1818 he returned to Vienna. Meanwhile he had published his collected *Gedichte* (1809) and two series of lectures, *Über die neuere Geschichte* (1811) and *Geschichte der alten und neuen Literatur* (1815). After his return to Vienna from Frankfort he edited *Concordia* (1820–23), and began the issue of his *Sämtliche Werke*. He also delivered lectures, which were republished in his *Philosophie des Lebens* (1828) and in his *Philosophie der Geschichte* (1829). He died on Jan. 11, 1829, at Dresden.

Friedrich Schlegel's wife, Dorothea, was the author of an unfinished romance, *Florentin* (1801), a *Sammlung romantischer Dichtungen des Mittelalters* (2 vols., 1804), a version of *Lother und Maller* (1805), and a translation of Madame de Staël's *Corinne* (1807–08)—all of which were issued under her husband's name.

Friedrich Schlegel's *Sämtliche Werke* appeared in 10 vols. (1822–25); a 2nd ed. (1846) in 15 vols. His *Prosaische Jugendschriften* (1794–1802) have been edited by J. Minor (1882, 2nd ed. 1906); there are also reprints of *Lucinde*, and F. Schleiermacher's *Vertraute Briefe über Lucinde, 1800* (1907). *See* I. Rouge, *F. Schlegel et la genèse du romantisme allemand* (1904) and *Erläuterungen zu F. Schlegels Lucinde* (1905); M. Joachimi, *Die Weltanschauung der Romantik* (1905); W. Glawe, *Die Religion F. Schlegels* (1906); E. Kircher, *Philosophie der Romantik* (1906); R. Volpers, *Friedrich Schlegel als politischer Denker und deutscher Patriot* (1917). On Dorothea Schlegel *see* J. M. Raich, *Dorothea von Schlegel und deren Söhne* (1881); F. Diebel, *Dorothea Schlegel als Schriftsteller im Zusammenhang mit der romantischen Schule* (1905).

SCHLEIERMACHER, FRIEDRICH DANIEL ERNST (1768–1834), German theologian and philosopher, was the son of a Prussian army chaplain of the Reformed confession, and was born on Nov. 21, 1768 at Breslau. He was educated in a Moravian school at Niesky in upper Lusatia, and at the Moravian seminary at Barby near Halle. Reluctantly his father permitted him to enter the university of Halle, which had already (1787) abandoned pietism and adopted the rationalist spirit of Wolf and Semler (*see* RATIONALISM). But though Schleiermacher left the Moravians he retained their intense religious spirit, and the years spent in their schools affected the whole course of his development. In his own life he reconciled personal emotional religion with a modified adoption of the Kantian critical philosophy. In 1796 he became chaplain to the Charité Hospital in Berlin. He was at that time profoundly affected by German Romanticism, as represented by his friend Friedrich Schlegel. This is evidenced by his *Confidential Letters* on Schlegel's *Lucinde* (*Vertraute Briefe über Schlegel's "Lucinde,"* 1801; ed. 1835; by Jonas Fränkel, 1907; R. Frank, 1907), as well as by his relation to Eleonore Grunow, the wife of a Berlin clergyman. Meantime he studied Spinoza and Plato, and was profoundly influenced by both, though he was never a Spinozist; he made Kant more and more his master, though he departed on fundamental points from him, and finally remodelled his philosophy; with some of Jacobi's positions he was in sympathy, and from Fichte and Schelling he accepted ideas, which in their place in his system, however, received another value and import. Schleiermacher was, in fact, a great eclectic. The literary fruit of this period of intense fermentation was his *Reden über die Religion* (1799; ed. Göttingen, 1906), and his "new year's gift" to the new century, the *Monologen* (1800; ed. 1902). In the first book he drew a sharp line between religion on the one hand and ethics and knowledge on the other. Religion is a matter of immediate intuition, he argued, whatever its manifestations and the dogmas with which it may be cloaked. In the *Monologen* he developed his ethical manifesto, in which he proclaimed his ideas as to the freedom and independence of the spirit; and as to the relation of the mind to the world of sense and imperfect social organizations. In these essays he emphasized individual personal development.

From 1802 to 1804, Schleiermacher was pastor in the little Pomeranian town of Stolpe. These years were full of literary work. He relieved Friedrich Schlegel entirely of his nominal responsibility for the translation of Plato, which they had together undertaken (vols. 1–5, 1804–10; 3rd. ed., 1855–61; vol. 6, *Repub.* 1828; 2nd ed., 1855–62); he was also occupied with *Grundlinien einer Kritik der bisherigen Sittenlehre* (1803; 2nd ed. 1834), the first of his strictly critical and philosophical productions. In the year 1804 Schleiermacher went as university preacher and professor of theology to Halle, where he remained until 1807. There he wrote his dialogue the *Weihnachtsfeier* (1806; 4th ed. 1850), which stands midway between his *Reden* and his great dogmatic work, *Der christliche Glaube*.

After the battle of Jena he returned to Berlin (1807), where he was appointed pastor of the Trinity church. The next year he married the widow of his friend Willich. At the foundation of the Berlin university (1810), he received a theological chair, and shortly afterward became secretary to the Academy of Sciences. Schleiermacher threw himself into the movement for national independence, acquiring a name and place in his country's annals with Arndt, Fichte, Stein and Scharnhorst. He shared in the reorganization of the Prussian church, and advocated, unsuccessfully, the union of the Lutheran and Reformed churches. In the *Kurze Darstellung des theologischen Studiums* (1811; 2nd ed. 1830), he sought to do for theology what he had done for religion in his *Reden*. His chief theological work *Der christliche Glaube nach den Grundsätzen der evangelischen Kirche* (1821–22; 2nd ed., greatly altered, 1830–31; 6th ed., 1884) is a classic, and has been described as the greatest theological work produced by Protestantism since the Reformation. Schleiermacher's aim was to reform Protestant theology by means of the fundamental ideas of the *Reden*, to put an end to the unreason and superficiality of both supernaturalism and rationalism, and to deliver religion and theology from a relation of dependence on perpetually changing systems of philosophy. His claim of the right of the church to frame its own liturgy in opposition to the arbitrary dictation of the state brought upon him fresh troubles. He felt himself more and more isolated in Berlin. But he continued his translation of Plato and prepared a new and greatly altered edition of his *Christliche Glaube*, anticipating the latter in two letters to his friend Lücke (in the *Studien und Kritiken*, 1829), in which he defended his theological position generally and his book in particular. He continued his defence against Hengstenberg's party on the one hand and the rationalists von Cölln and D. Schulz on the other, protesting against both subscription to the ancient creeds and the imposition of a new rationalistic formulary. He died, after a few days' illness, on Feb. 12, 1834.

Philosophical System.—Schleiermacher maintained that the world and God are distinct, but correlative, and neither can be conceived without the other. The world without God would be "chaos," and God without the world an empty "phantasm." But though God is transcendent and unknowable he is immanent in the world. In self-consciousness God is present as the basis of the unity of our nature in every transition from an act of knowledge to an act of will, and vice versa. As far as man is the unity of the real and the ideal, God is in him. He is also in all things, inasmuch as in everything the totality of the world and its transcendental basis is presupposed by virtue of their being and correlation. The unity of our personal life amidst the multiplicity of its functions is the symbol of God's immanence in the world, though we may not conceive of the Absolute as a person. Though He may not be conceived as the absolute cause of the world, the idea of absolute causality as symbolized in it may be taken as the best approximate expression of the contents of the religious consciousness. The unbroken connection of cause and effect throughout the world becomes thus a manifestation of God. God is to be sought only in ourselves and in the world. He is completely immanent in the universe. It is impossible that His causality should

have any other sphere than the world, which is the totality of being. "No God without a world, and no world without God." The divine omnipotence is quantitatively represented by the sum of the forces of nature, and qualitatively distinguished from them only as the unity of infinite causality from the multiplicity of its finite phenomena. Throughout the world—not excepting the realm of mind—absolute necessity prevails. As a whole the world is as good and perfect as a world could possibly be, evil being only the necessary limitation of individual being.

Ethics.—In his earlier essays Schleiermacher pointed out the defects of ancient and modern ethical thinkers, particularly of Kant and Fichte, favouring only Plato and Spinoza. His own ethics connects the moral world by a deductive process with the fundamental idea of knowledge and being; it offers a view of the entire world of human action; it presents an arrangement of the matter of the science which tabulates its constituents after the model of the physical sciences; and it supplies a sharply defined treatment of specific moral phenomena in their relation to the fundamental idea of human life as a whole. Schleiermacher defines ethics as the theory of the nature of the reason, or as the scientific treatment of the effects produced by human reason in the world of nature and man. The ontological basis of ethics is the unity of the real and the ideal, and the psychological and actual basis of the ethical process is the tendency of reason and nature to unite in the form of the complete organization of the latter by the former. The end of the ethical process is that corporeal nature may become the perfect symbol and organ of mind. Conscience, as the subjective expression of the presupposed identity of reason and nature in their bases, guarantees the practicability of our moral vocation. Nature is preordained or constituted to become the symbol and organ of mind, just as mind is endowed with the impulse to realize this end. But the moral law must not be conceived under the form of an "imperative"; it differs from a law of nature only as being descriptive of the fact that it ranks the mind as conscious will above nature. Strictly speaking, the antitheses of good and bad and of free and necessary have no place in an ethical system, but simply in history, which is obliged to compare the actual with the ideal; but as far as the terms "good" and "bad" are used in morals they express the rule or the contrary of reason, or the harmony of the contrary of the particular and the general. The idea of "free" as opposed to necessary expresses simply the fact that the mind can propose to itself ends, though a man cannot alter his own nature. In contrast to Kant and Fichte and modern moral philosophers Schleiermacher assigned pre-eminent importance to the doctrine of the *summum bonum,* or highest good. It represents in his system the aim of the entire life of man, supplying the ethical view of the conduct of individuals in relation to society and the universe, and therewith constituting a philosophy of history at the same time. Moral functions cannot be performed by the individual in isolation but only in relation to the family, the state, the school, the church, and society—all forms of human life which ethical science finds to its hand and leaves to the science of natural history to account for. Duties are divided with reference to the principle that every man make his own the entire moral problem and act at the same time in an existing moral society. This condition gives four general classes of duty: duties of general association or duties with reference to the community (*Rechtspflicht*), and duties of vocation (*Berufspflicht*)—both with a universal reference, duties of the conscience (in which the individual is sole judge), and duties of love or of personal association. It was only the first of the three sections of the science of ethics—the doctrine of moral ends—that Schleiermacher handled with approximate completeness. In his *Christian Ethics* he dealt with the subject from the basis of the Christian consciousness instead of from that of reason generally; the ethical phenomena dealt with are the same in both systems, and they throw light on each other, while the Christian system treats more at length and less aphoristically the principal ethical realities—church, state, family, art, science and society.

Religious System.—From Leibniz, Lessing, Fichte, Jacobi and the Romantic school Schleiermacher had imbibed a profound mystical view of human personality. The ego, the person, is an individualization of universal reason; and the primary act of self-consciousness is the first conjunction of universal and individual life. Thus every person becomes a specific and original representation of the universe. While therefore we cannot, as we have seen, attain the idea of the supreme unity of thought and being by either cognition or volition, we can find it in our own personality, in immediate self-consciousness or (which is the same in Schleiermacher's terminology) feeling. Feeling in this higher sense (as distinguished from "organic" sensibility), which is the minimum of distinct antithetic consciousness, the cessation of the antithesis of subject and object, constitutes likewise the unity of our being, in which the opposite functions of cognition and volition have their permanent background of personality and their transitional link. Having its seat in this central point of our being, or indeed consisting in the essential fact of self-consciousness, religion lies at the basis of all thought and action. In his earlier days he called it a feeling or intuition of the universe, consciousness of the unity of reason and nature, of the infinite and the eternal within the finite and the temporal. In later life he described it as the feeling of absolute dependence, or, as meaning the same thing, the consciousness of being in relation to God. As in every affection of our being by individual phenomena we are brought into contact with the whole universe, we are brought into contact with God at the same time as its transcendental cause. This religious feeling is not knowledge in the strict sense, as it is purely subjective or immediate; but it lies at the basis of all knowledge. The so-called natural as distinguished from positive religion, or the religion of reason, is a mere abstraction. All religions are positive, or their characteristics and value are mainly determined by the manner in which the world is conceived. But these varying conceptions with their religious meaning become religiously productive only in the souls of religious heroes, who are the authors of new religions, mediators of the religious life, founders of religious communities. For religion is essentially social, and everywhere forms churches, the necessary organs of its highest life. The specific feature of Christianity is its mediatorial element, its profound feeling of the striving of the finite individual to reach the unity of the infinite whole, and its conception of the way in which Deity deals with this effort by mediatorial agencies, which are both divine and human. Its adherents are conscious of having been delivered by Christ from a condition in which their religious consciousness was overridden by the sense-consciousness of the world and put into one in which everything is subordinated to it. The mediator is now the Christian church, but in the case of Jesus, its originator, it was an entirely new and original factor in the process of religious development, and in so far, like every new and higher stage of being, a supernatural revelation. The appearance of the Saviour in human history is therefore as a divine revelation neither absolutely supernatural nor absolutely beyond reason, and the controversy of the 18th century between the rationalists and supernaturalists rests on false grounds, leads to wrong issues, and each party is right and wrong (*see* Rationalism). As regards Christian theology, it is not its business to establish a system of objective truth, but simply to present in a clear connected form a given body of Christian faith as the contents of the Christian consciousness. Dogmatic theology is a connected accurate account of the doctrine held at a particular time in a given section of the Christian church. But such doctrines as constitute no integral part of the Christian consciousness—*e.g.*, the doctrine of the Trinity—must be excluded from the theological system of the evangelical theologian. As regards the relation of theology and philosophy, it is not one of dependence or of opposition, but of complete independence, equal authority, distinct functions and perfect harmony.

The marked feature of Schleiermacher's thought in every department is the effort to combine the antithetic conceptions of other thinkers. He is realistic and idealistic, individualistic and universalistic, monistic and dualistic, sensationalist and intellectualist, naturalist and supernaturalist, rationalist and mystic, gnostic and agnostic. Apart from the positive and permanent value of the higher unities which he succeeds in establishing, the suggestiveness of his discussions of the great points at issue in all the principal fields of human thought, unsatisfactory as many of

his positions may be considered, make him one of the most instructive of modern thinkers. And, since the focus of his almost universal thought and inquiry and of his rich culture was religion and theology, he must be regarded as the classical representative of modern effort to reconcile science and philosophy with religion and theology, and the modern world with the Christian church.

Schleiermacher's collected works were published in three sections: (1) Theological (11 vols.); (2) Sermons (10 vols., ed. 1873–74, 5 vols.); (3) Philosophical and Miscellaneous (9 vols., 1835–64). His *Pädagogische Schriften* were separately published by Platz (3rd ed., 1902). Of lives the best are his own correspondence; *Aus Schleiermachers Leben in Briefen*, by W. Dilthey (1858–63, in 4 vols., Eng. trans. by Rowan); *Leben Schleiermachers* by Dilthey (vol. i., 1870, the period from 1768–1804); *Friedrich Schleiermacher, ein Lebens- und Charakterbild*, by D. Schenkel (Elberfeld, 1868); a selection of the letters by M. Rade (Jena, 1906). *See* also E. von Willick, *Aus Schleiermachers Hause, Jugenderinnerungen seines Stiefsohnes* (1909). The accounts and critiques of his philosophy, ethics and theology are numerous; some of the most valuable are: J. Schaller, *Vorlesungen über Schleiermacher* (Halle, 1844); G. Weisenborn, *Darstellung und Kritik der Schleiermacher'schen Glaubenslehre* (1849); F. Vorländer, *Schleiermachers Sittenlehre* (Marburg, 1851); W. Bender, *Schleiermachers Theologie mit ihren philosophischen Grundlagen* (1876–78); O. Ritschl, *Schleiermachers Stellung zum Christentum in seinen Reden über die Religion* (1888); and *Schleiermachers Theorie von der Frömmigkeit* (1897); O. Kirn, *Schleiermacher und die Romantik* (1895); H. Bleek, *Die Grundlagen der Christologie Schleiermachers* (1898); M. Fischer, *Schleiermacher* (1899); Lülmann, *Das Bild des Christentums bei den grossen deutschen Idealisten* (1901), and *Schleiermacher der Kirchenvater des 19. Jahrhunderts* (1907); Stephan, *Die Lehre Schleiermachers von der Erlösung* (1901); Theile, *Schleiermachers Theologie und ihre Bedeutung für die Gegenwart* (1903); G. Thimme, *Die religionsphilosophischen Prämissen der Schleiermacher'schen Glaubenslehre* (1901); H. Sueskind, *Der Einfluss Schellings auf die Entwicklung von Schleiermachers System* (1909); F. Kattenbusch, *Von Schleiermacher zu Ritschl* (1903); E. Cramaussel, *La Philosophie religieuse de Schleiermacher* (1909). Full bibliography in Überweg, *Grundriss der Gesch. der Philosophie*, Bd. 4 (1923).

(J. F. Sm.; X.)

SCHLESWIG, town and capital of the Prussian province of Schleswig-Holstein on the narrow arm of the sea called the Schlei, 30 m. to the N.W. of Kiel on the railway from Hamburg to Flensburg. Pop. (1925) 18,683. The town consists mainly of a single street, 3½ m. long, forming a semicircle round the Schlei. The church of St. Peter (1100), renewed in the Gothic style in the 15th century, contains a fine carved oak reredos by Hans Brüggemann. The former commercial importance of the town has disappeared, and the Schlei now affords access to small vessels only. Fishing, tanning, flour-milling and gardening are the chief industries.

History.—Schleswig (ancient forms *Sliesthorp, Sliaswic, i.e.,* the town or bay of the Slia or Schlei) seems to have been already a place of importance in the 9th century, as a medium of trade between the North Sea and the Baltic. The first Christian church was built here by Ansgarius (d. 865), and it became the seat of a bishop about a century later. The town, which obtained civic rights in 1200, also became the seat of the dukes of Schleswig, but its commerce gradually dwindled owing to the rivalry of Lübeck, the wars in which the district was involved, and the silting up of the Schlei. At the partition of 1544 the old castle of Gottorp, built in 1160 for the bishop, became the seat of the Gottorp line of the Schleswig-Holstein family, which remained here till expelled by the Danish king Frederick IV. in 1713. From 1731 to 1846 it was the seat of the Danish governor of the duchies. For later history *see* Schleswig-Holstein Question.

SCHLESWIG-HOLSTEIN, a province in the north-west of Prussia, formed out of the once Danish duchies of Schleswig, Holstein and Lauenburg, and bounded west by the North Sea, north by Denmark, east by the Baltic Sea, Lübeck and Mecklenburg, and south by the lower course of the Elbe (separating it from Hanover). It thus consists of the southern half of the Cimbric peninsula, and forms the connecting link between Germany and Denmark. As a result of the plebiscite taken in accordance with the Treaty of Versailles in 1920, the Northern Zone of the existing German province of Schleswig-Holstein was restored to Denmark, while the Southern Zone remained part of German territory. The new boundary line runs just north of Sylt, south of Tønder and north of Flensburg. In addition to the mainland, which decreases in breadth from south to north, the province includes several islands, the most important being Fehmarn in the Baltic, and Heligoland, Sylt and Föhr in the North Sea. The total area of the province is 5,815 sq.m.

The more ancient geological formations are scarcely met with in Schleswig-Holstein. The contrast between the two coast-lines of the province is marked. The Baltic coast has generally steep well-defined banks and is irregular, being pierced by numerous long and narrow inlets (*Föhrden*) which often afford excellent harbours. The North Sea coast is low and flat, and its smooth outline is interrupted only by the estuary of the Eider and the peninsula of Eiderstedt. Dunes or sand-hills, though rare on the protected mainland, occur on Sylt and other islands, while the small flat islands called *Halligen* require protection by dykes.

The climate of Schleswig-Holstein is mainly determined by the proximity of the sea, and the mean annual temperature, varying from 45° in the north to 49° in the south, is rather higher than is usual in the same latitude. Rain and fog are frequent, but the climate is on the whole healthy. The Elbe forms the southern boundary of Holstein for 65 m., but the only river of importance within the province is the Eider, which rises in Holstein, and after a course of 120 m. falls into the North Sea, forming an estuary 3 to 12 m. in breadth. It is navigable from its mouth as far as Rendsburg, which is on the Kaiser Wilhelm (Kiel-Elbe) canal, which intersects Holstein. There are numerous lakes in north-east Holstein, the largest of which are the Plöner See (12 sq.m.) and the Selenter See (9 sq.m.).

The ordinary cereals are all cultivated with success and there is generally a considerable surplus for export. Rape is grown in the marsh lands and flax on the east coast, while large quantities of apples and other fruit are raised near Altona for the Hamburg and English markets. The marsh lands afford admirable pasture, and great numbers of cattle are reared for export. The Holstein horses are also in request, but sheep-farming is comparatively neglected. Bee-keeping is a productive industry. The hills skirting the bays of the Baltic coast are generally pleasantly wooded, but the forests are nowhere of great extent except in Lauenburg. The fishing in the Baltic is productive; Eckernförde is the chief fishing station in Prussia. The oysters from the beds on the west coast of Schleswig are widely known under the misnomer of "Holstein natives." The mineral resources are almost confined to a few layers of rock-salt near Segeberg. The more important industrial establishments, such as iron foundries, machine works, tobacco and cloth factories, are mainly confined to the large towns, such as Altona, Kiel and Flensburg. The shipbuilding of Kiel and other seaports, however, is important. The commerce and shipping of Schleswig-Holstein, stimulated by its position between two seas, as well as by its excellent harbours and waterways, are much more prominent than its manufactures. Kiel is one of the chief seaports of Prussia, while oversea trade is also carried on by Altona and Flensburg. Schleswig is the official capital of the province, but Altona and Kiel are the largest towns. The main exports are grain, cattle, horses, fish and oysters, in return for which come timber, coal, salt, wine and colonial produce.

The population of the province in 1925 was 1,529,909. Among the Germans the prevalent tongue is Low German, but the North Frisians on the west coast of Schleswig and the North Sea islands still speak a Frisian dialect, which, however, is dying out. The peninsula of Angeln, between the Gulf of Flensburg and the Schlei, is supposed to have been the original seat of the English, and observers profess to see a striking resemblance between this district and the counties of Kent and Surrey. The peasants of Dithmarschen in the south-west retain many of their ancient peculiarities. The language boundary between Danish and German now practically coincides with the political boundary. The chief educational institution in Schleswig-Holstein is the university of Kiel.

SCHLESWIG-HOLSTEIN QUESTION, the name given to the whole complex of diplomatic and other issues arising in the 19th century out of the relations of the two "Elbe duchies," Schleswig and Holstein, to the Danish Crown on the one hand

and the German Confederation on the other, which came to a crisis with the extinction of the male line of the reigning house of Denmark by the death of King Frederick VII. on Nov. 15, 1863. The central question was whether the two duchies did or did not constitute an integral part of the dominions of the Danish Crown, with which they had been more or less intimately associated for centuries. This involved the purely legal question, raised by the death of the last common male heir to both Denmark and the duchies, as to the proper succession in the latter, and the constitutional questions arising out of the relations of the duchies to the Danish crown, to each other, and of Holstein to the German Confederation. There was also the national question: the ancient racial antagonism between German and Dane, intensified by the tendency, characteristic of the 19th century, to the consolidation of nationalities. Lastly, there was the international question: the rival ambitions of the German powers involved, and beyond them the interests of other European States, notably that of Great Britain, in preventing the rise of a German sea-power in the north.

Early History.—From time immemorial the country north of the Elbe had been the battle-ground of Danes and Germans. Danish scholars point to the prevalence of Danish place-names far southward into the German-speaking districts as evidence that at least the whole of Schleswig was at one time Danish, *i.e.*, place-names according to popular usage, not the official names given in German maps (*e.g.*, Haderslev for Hadersleben. See *La Question du Slesvig*, p. 61 *seq.*, "Noms de lieux"). German scholars claim it, on the other hand, as essentially German. That the duchy of Schleswig, or South Jutland (Sönderjylland), had been from time immemorial a Danish fief was, indeed, not in dispute, nor was the fact that Holstein had been from the first a fief of the Germano-Roman empire. The controversy in the 19th century raged round the "indissoluble" union of the two duchies, the principle of which had been secured by the Charter of Ribe, signed by the Danish King Christian I., in 1460, after his election by the respective estates as count of Holstein and duke of Schleswig. The "Eider Danes" (*i.e.*, the party at Copenhagen which aimed at making the Eider, the southern boundary of Schleswig, the frontier of the Danish kingdom proper) claimed Schleswig as an integral part of the Danish monarchy, which, on the principle of the union, involved the retention of Holstein also; the Germans claimed Holstein as a part of Germany and, therefore, on the same historic principle, Schleswig also.

The Congress of Vienna, instead of settling the questions involved in the relations of the duchies of Denmark once for all, sought to stereotype the old divisions in the interests of Germany. In 1806, after the dissolution of the Holy Roman empire, the duchies had been virtually incorporated in Denmark. This settlement was reversed by the Congress, and while Schleswig remained as before, Holstein and Lauenburg were included in the new German Confederation. The opening up of the Schleswig-Holstein question thus became sooner or later inevitable. The Germans of Holstein, influenced by the new national enthusiasm evoked by the War of Liberation, resented more than ever attempts to treat them as part of the Danish monarchy and, encouraged by the sympathy of the Germans in Schleswig, tried to reassert in the interests of Germanism the old principle of the unity of the duchies. The political atmosphere, however, had changed at Copenhagen also; and their demands were met by the Danes with a nationalist temper as intractable as their own. Affairs were ripe for a crisis, which the threatened failure of the common male heirs to the kingdom and the duchies precipitated.

CRISIS OF 1848–49

When Christian VIII. succeeded his father Frederick VII. in 1839 the elder male line of the house of Oldenburg was on the point of extinction, the king's only son and heir having no children. To German opinion the solution of the question of the succession seemed clear enough. The Crown of Denmark could be inherited by female heirs; in the duchies the Salic law had never been repealed and, in the event of a failure of male heirs to Christian VIII., the succession would pass to the dukes of Augustenburg. Danish opinion, on the other hand, clamoured for a royal pronouncement proclaiming the principle of the indivisibility of the monarchy and its transmission intact to a single heir, in accordance with the royal law. To this Christian VIII. yielded so far as to issue in 1846 letters patent declaring that the royal law in the matter of the succession was in full force so far as Schleswig was concerned. As to Holstein he stated that he could not give so clear a decision, but the principle of the independence of Schleswig and of its union with Holstein were expressly reaffirmed. An appeal against this by the estates of Holstein to the German diet received no attention. The revolutionary year 1848 brought matters to a head. On Jan. 28, Christian VIII. proclaimed a new constitution which, while preserving the autonomy of the different parts of the country, incorporated them for common purposes in a single organization. The estates of the duchies replied by demanding the incorporation of Schleswig-Holstein, as a single constitutional state, in the German Confederation. Frederick VII., who had succeeded his father at the end of January, declared (March 4) that he had no right to deal in this way with Schleswig, and, yielding to the Eider-Danish party, withdrew the rescript of January (April 4) and announced to the people of Schleswig (March 27) the promulgation of a liberal constitution under which the duchy, while preserving its local autonomy, would become an integral part of Denmark.

Prussian Intervention.—Meanwhile the duchies had broken out into insurrection; a provisional Government had been established at Kiel; and the duke of Augustenburg had hurried to Berlin to secure the assistance of Prussia in asserting his rights. This was at the very crisis of the revolution in Berlin, and the Prussian Government saw in the proposed intervention in Denmark in a popular cause an excellent opportunity for restoring its damaged prestige. Prussian troops were accordingly marched into Holstein and, the diet having on April 12 recognized the provisional Government of Schleswig and commissioned Prussia to enforce its decrees, General Wrangel was ordered to occupy Schleswig also. Prussia, as the mandatory of Germany, endeavoured to enforce the principle that the states were independent, indissolubly united and hereditary only in the male line. But the Germans had reckoned without the European powers, which were united in opposing any dismemberment of Denmark, even Austria refusing to assist in enforcing the German view.

Convention of Malmoe.—Prussia was now confronted on the one side by the German nation urging her to action, on the other side by the European powers threatening the worst consequences should she persist. Frederick William chose the lesser of two evils and, on Aug. 26, 1848, Prussia signed at Malmoe a convention which yielded practically all the Danish demands. The Holstein estates appealed to the German parliament, but it was soon clear that this had no means of enforcing its views, and the convention was ratified at Frankfort.

The convention was only in the nature of a truce establishing a temporary *modus vivendi*, and the main issues continued to be hotly debated. A conference held in London failed to arrive at a settlement, and on April 3, 1849, the war was renewed. But the European situation, and notably the attitude of the Emperor Nicholas I. of Russia—who looked on Augustenburg as a rebel and Russia as bound in honour to safeguard the interests of the Danish Crown—decided Prussia to conclude peace with Denmark on the basis of the *status quo ante bellum*.

Treaty of Berlin, 1850.—The treaty was signed at Berlin on July 2, 1850. Both parties reserved all their antecedent rights; but for Denmark it was enough, since it empowered the king-duke to restore his authority in Holstein with or without the consent of the German Confederation. Danish troops marched in to coerce the duchies; but, meanwhile, negotiations among the powers continued, and on Aug. 2, 1850, Great Britain, France, Russia and Norway-Sweden signed a protocol, to which Austria subsequently adhered, approving the principle of restoring the integrity of the Danish monarchy. On Jan. 28, 1852, King Frederick VII. issued a royal letter announcing the institution of a unitary State which, while maintaining the fundamental con-

stitution of Denmark, would increase the powers of the estates of the two duchies. This was approved by Prussia and Austria, and by the German federal diet in so far as it affected Holstein and Lauenburg.

The Protocol of London, 1852.—The question of the succession was next approached. The main obstacle to an agreement among the Powers was removed when, on March 31, 1852, the duke of Augustenburg resigned his claim in return for a money payment. Further adjustments followed. After the renunciation by the emperor of Russia (who represented the elder, Gottorp line) and others of their eventual rights, Charlotte, landgravine of Hesse, sister of Christian VIII., and her son Prince Frederick transferred their rights to the latter's sister Louise, who in her turn transferred them to her husband Prince Christian of Glücksburg. This arrangement received international sanction by the protocol signed in London on May 8, 1852, by the five great powers and Norway and Sweden. On July 31, 1853, King Frederick VII. gave his assent to a law settling the crown on Prince Christian, "prince of Denmark," and his heirs male. The protocol of London, while consecrating the principle of the integrity of Denmark, stipulated that the rights of the German Confederation in Holstein and Lauenburg should remain unaffected. It was, in fact, a compromise which satisfied neither the Danes nor the Germans; and when in Oct. 1855, King Frederick issued a parliamentary constitution for the whole monarchy, its legality was disputed by the two German great powers, on the ground that the estates of the duchies had not been consulted, and the diet of the Confederation refused to admit its validity so far as Holstein and Lauenburg were concerned (Feb. 11, 1858).

The question was now once more the subject of international debate; but the situation was no longer so favourable to the Danish view. The Crimean War had crippled Russia, and Nicholas I. was dead. France was prepared to sell the interests of Denmark in the duchies to Prussia in return for "compensations" to herself elsewhere. Great Britain alone sided with the Danes; but the action of British ministers, who realized the danger to British supremacy at sea of the growth of German sea-power in the Baltic, was hampered by the natural sympathy of Queen Victoria and the prince consort with the German point of view[1]. The result was that the German diet, on the motion of Bismarck, having threatened federal intervention (July 29), Frederick VII. abolished the general constitution so far as it affected Holstein and Lauenburg, while retaining it for Denmark and Schleswig (Nov. 6).

CRISIS OF 1863–64

Though even this concession violated the principle of the "indissoluble union" of the duchies, the German diet, fully occupied at home, determined to refrain from further action till the Danish parliament should make another effort to pass a law or budget affecting the whole kingdom without consulting the estates of the duchies. This contingency arose in July 1860, and in the spring of the following year the estates were once more at open odds with the Danish Government. The German diet now prepared for armed intervention; but it was in no condition to carry out its threats, and Denmark decided, on the advice of Great Britain, to ignore it and open negotiations directly with Prussia and Austria as independent Powers. These demanded the restoration of the union between the duchies, a question beyond the competence of the Confederation. Denmark replied with a refusal to recognize the right of any foreign Power to interfere in her relations with Schleswig; to which Austria, anxious to conciliate the smaller German princes, responded with a vigorous protest against Danish infringements of the compact of 1852. Lord John Russell now intervened, on behalf of Great Britain, with a proposal for a settlement of the whole question on the basis of the independence of the duchies under the Danish Crown[2]. This was accepted by Russia and by the German great powers, and Denmark found herself isolated. The international situation, however, favoured a bold attitude, and she met the representations of the powers with a flat defiance. The retention of Schleswig as an integral part of the monarchy was to her a matter of life and death; the German Confederation had made the terms of the protocol of 1852, defining the intimate relations between the duchies, the excuse for unwarrantable interference in the internal affairs of Denmark; and on March 30, 1863, a royal proclamation was published at Copenhagen repudiating the compacts of 1852, and, by defining the separate position of Holstein in the Danish monarchy, negativing the claims of Germany upon Schleswig[3].

Danish Constitution of 1863.—The reply of the German diet was a note to Copenhagen (July 9) demanding, on pain of federal execution, the withdrawal of the proclamation and the grant of a constitution based on the compacts of 1852 or on the British note of Sept. 24, 1862. Instead, King Frederick VII. issued on Sept. 28, 1863, a new constitution for "our kingdom of Denmark-Slesvig," which, encouraged by the hesitating attitude of the German diet, the Danish parliament passed on Nov. 13. Two days later Frederick VII. died.

The "Protocol-King," Christian IX., who now ascended the throne, was in a difficult position. The first act he was called upon to perform was to sign the new constitution. To sign was to violate the terms of the very protocol which was his title to reign; to refuse to sign was to defy the sentiment of his Danish subjects. He chose what seemed the remoter evil, and on Nov. 18 signed the constitution. The news was received in Germany with violent manifestations of anger. Frederick, duke of Augustenburg, son of the prince who in 1852 had renounced the succession to the duchies, now claimed his rights on the ground that he had had no share in the renunciation. In Holstein an agitation in his favour had begun from the first, and this was extended to Schleswig on the terms of the new Danish constitution becoming known. His claim was enthusiastically supported by the German princes and people, and in spite of the negative attitude of Austria and Prussia the federal diet decided to occupy Holstein "pending the settlement of the succession." On Dec. 24 Saxon and Hanoverian troops marched into the duchy in the name of the German Confederation, and supported by their presence and by the loyalty of the Holsteiners the duke of Augustenburg assumed the Government under the style of Duke Frederick VIII.

Attitude of Austria and Prussia.—With this "folly"—as Bismarck roundly termed it—Austria and Prussia, in the teeth of violent public opinion, would have nothing to do, for neither wished to risk a European war. It was clear to Bismarck that the two powers, as parties to the protocol of 1852, must uphold the succession as fixed by it, and that any action they might take in consequence of the violation of that compact by Denmark must be so "correct" as to deprive Europe of all excuse for interference. The publication of the new constitution by Christian IX. was in itself sufficient to justify a declaration of war by the two powers as parties to the signature of the protocol. As to the ultimate outcome of their effective intervention, that could be left to the future to decide. Austria had no clear views. King William wavered between his Prussian feeling and a sentimental sympathy with the duke of Augustenburg. Bismarck alone knew exactly what he wanted, and how to attain it. "From the beginning," he said later (*Reflections*, ii. 10), "I kept annexation steadily before my eyes."

The protests of Great Britain and Russia against the action of the German diet helped Bismarck to persuade Austria that immediate action must be taken. On Dec. 28 a motion was introduced in the diet by Austria and Prussia, calling on the Confederation to occupy Schleswig as a pledge for *the observance by Denmark of the compacts of 1852.* This implied the recognition of the rights of Christian IX., and was indignantly rejected; whereupon the diet was informed that Austria and Prussia would act in the matter as independent European Powers. The agreement between them was signed on Jan. 16, 1864. One article stated

[2]Note of Sept. 24, 1862. For the diplomatic correspondence on the duchies see *Parl. Papers*, lxxiv. (1863).

[3]For this and later correspondence see *Parl. Papers*, lxiv. (1864) p. 40 *seq.*

that the two Powers would decide only in concert on the relations of the duchies, and that they would in no case determine the question of the succession save by mutual consent.

At this stage, had the Danes yielded to the necessities of the situation and withdrawn from Schleswig under protest, the European Powers would probably have intervened, a congress would have restored Schleswig to the Danish Crown, and Austria and Prussia, as European Powers, would have had no choice but to prevent any attempt upon it by the duke of Holstein. To prevent this possibility Bismarck made the Copenhagen Government believe that Great Britain had threatened Prussia with intervention should hostilities be opened, "though, as a matter of fact, England did nothing of the kind." The cynical stratagem succeeded; Denmark remained defiant; and on Feb. 1, 1864, the Austrian and Prussian forces crossed the Eider.

The Danish War.—An invasion of Denmark itself had not been part of the original programme of the allies; but on Feb. 18 some Prussian hussars, in the excitement of a cavalry skirmish, crossed the frontier and occupied the village of Kolding. Bismarck determined to use this circumstance to revise the whole situation. He urged upon Austria the necessity for a strong policy, so as to settle once for all not only the question of the duchies but the wider question of the German Confederation; and Austria reluctantly consented to press the war. On March 5 a fresh agreement was signed between the Powers, under which the compacts of 1852 were declared to be no longer valid, and the position of the duchies within the Danish monarchy as a whole was to be made the subject of a friendly understanding. Meanwhile, however, Lord John Russell on behalf of Great Britain, supported by Russia, France and Sweden, had intervened with a proposal that the whole question should once more be submitted to a European conference[1]. The German Powers agreed on condition that the compacts of 1852 should not be taken as a basis, and that the duchies should be bound to Denmark by a personal tie only. But the proceedings of the conference, which opened at London on April 25 only revealed the inextricable tangle of the issues involved. Beust, on behalf of the Confederation, demanded the recognition of the Augustenburg claimant; Austria leaned to a settlement on the lines of that of 1852; Prussia, it was increasingly clear, aimed at the acquisition of the duchies. The first step towards the realization of this latter ambition was to secure the recognition of the absolute independence of the duchies, and this Austria could only oppose at the risk of forfeiting her whole influence in Germany. The two Powers, then, agreed to demand the complete political independence of the duchies bound together by common institutions. The next move was uncertain. As to the question of annexation Prussia would leave that open, but made it clear that any settlement must involve the complete military subordination of Schleswig-Holstein to herself. This alarmed Austria, which had no wish to see a further extension of Prussia's already overgrown power, and she began to champion the claims of the duke of Augustenburg. This contingency, however, Bismarck had foreseen and himself offered to support the claims of the duke at the conference if he would undertake to subordinate himself in all naval and military matters to Prussia, surrender Kiel for the purposes of a Prussian war-harbour, give Prussia the control of the projected North Sea Canal, and enter the Prussian Customs Union. On this basis, with Austria's support, the whole matter might have been arranged without—as Beust pointed out (*Mem.* i. 272)—the increase of Prussia's power beyond the Elbe being any serious menace to Austrian influence in Germany. Fortunately, however, for Bismarck's plans, Austria's distrust of Prussia led her to oppose this settlement and at her instigation the duke of Augustenburg rejected it.

Treaty of Vienna, 1864.—On June 25 the London conference broke up without having arrived at any conclusion. On the 24th, in view of the end of the truce, Austria and Prussia had arrived at a new agreement, the object of the war being now declared to be the complete separation of the duchies from Denmark. As the result of the short campaign that followed, the preliminaries of a treaty of peace were signed on Aug. 1, the king of Denmark renouncing all his rights in the duchies in favour of the emperor of Austria and the king of Prussia. The definitive treaty was signed at Vienna on Oct. 30, 1864. By Article XIX., a period of six years was allowed during which the inhabitants of the duchies might "opt" for Danish nationality and transfer themselves and their goods to Denmark; and the right of "indigenacy" was guaranteed to all, whether in the kingdom or the duchies, who enjoyed it at the time of the exchange of ratification of the treaty[2].

[1] *Parl. Papers* (1864), lxv. 124 *seq.* Beust (*Mem.* i. 252) says that Queen Victoria personally intervened to prevent British action in favour of Denmark.

SETTLEMENTS OF 1866 AND 1920

The Schleswig-Holstein Question from this time onward became merged in the larger question of the general relations of Austria and Prussia. So far as Europe was concerned it was settled by the decisive result of the Austro-Prussian war of 1866. (*See* SEVEN WEEKS' WAR.) It survived, however, as between Danes and Germans, though narrowed down to the question of the fate of the Danish population of the northern duchy.

By Article V. of the Treaty of Prague (Aug. 23, 1866) Schleswig was ceded by Austria to Prussia with the reservation that "the populations of the North of Schleswig shall be again united with Denmark in the event of their expressing a desire so to be by a vote freely exercised." But the *plébiscite* never came. Its inclusion in the treaty had been no more than a diplomatic device to save the face of the emperor Napoleon III.; Prussia had from the first no intention of surrendering an inch of the territory she had conquered; the outcome of the Franco-German War made it unnecessary for her even to pretend that she might do so; and by the Treaty of Vienna of Oct. 11, 1878, the clause relating to the *plébiscite* was formally abrogated with the assent of Austria.

To incorporate Schleswig in the German empire, however, was one thing; to absorb its people into the German nation quite another. South Schleswig was already German; but for 50 years Germanism, backed by all the weight of the empire and imposed with the weapons of official persecution, had not held its own in North Schleswig; in spite of an enormous emigration, in 1905, of the 148,000 inhabitants of North Schleswig 139,000 spoke Danish, while of the German-speaking immigrants it was found that more than a third spoke Danish in the first generation; and this in spite of the fact that, from 1864 onward, German had gradually been substituted for Danish in the churches, the schools, and even in the playground. But the scattered outposts of Germanism could hardly be expected to acquiesce without a struggle in a situation that threatened them with social and economic extinction. Fifty years of dominance, secured by official favour, had filled them with a double measure of aggressive pride of race, and the question of the rival nationalities in Schleswig, like that in Poland, remained a source of trouble and weakness within the frontiers of the German empire.

During the years preceding the World War, the efforts to Germanize the Danish inhabitants of Schleswig continued, but only succeeded in strengthening their Danish national consciousness. In Aug. 1914 the effects of this spirit were so feared in Germany that a number of prominent Danes were imprisoned, and during the War the aspirations for union with Denmark were silenced. On the one hand, there was the German censorship, and on the other hand, the Danes themselves in Schleswig did not wish to endanger Denmark's neutrality.

On Oct. 23, 1918, however, H. P. Hanssen, a Danish representative, raised the demand for reunion in the German *Reichstag;* on the same day the Danish *Rigsdag* passed a resolution in favour of a readjustment of the frontier on the principles of nationality. On Nov. 28 the Danish Government communicated its wishes to the Allies, and in Feb. 1919 a united Danish North Schleswig delegation was sent to the Peace Conference in Paris to present the Danish point of view: a plebiscite *en bloc* in North Schleswig (zone 1); a community ballot in Central Schleswig and Flens-

[2] The full text of the treaty is in *La Question du Slesvig,* p. 173 *et seq.*

burg (zone 2) and voting rights to all those born in the voting district. The Peace Treaty, presented May 7, further provided for a plebiscite in a third zone, but this was later dropped.

On the treaty coming into force (Jan. 10, 1920) an international commission took charge of the plebiscite district. Zone 1 gave 75,431 votes for Denmark, 25,329 for Germany (Feb. 10); zone 2, 48,148 votes for Germany, 13,029 for Denmark (March 14). The frontier established by the treaty of July 5, 1920 gave effect to this verdict, and restored to Denmark that part of Schleswig which lies north of the Flensburg fjord, and of a line drawn approximately west from it. On July 7 the executive power in Zone 1 was handed over to Denmark.

Subsequent elections have shown the line to be fairly drawn. The Danish vote polled in Germany in 1924 was 7,700—insufficient to return a Danish representative. The German votes for the *Rigsdag* in 1921 and 1924 totalled 7,500, returning one member under the system of proportional representation. The Treaty of Versailles imposed no special obligations upon Denmark with regard to her German minority, since the Danish constitution offered adequate safeguards; on the same grounds the Danish Government declined the proposal for a special treaty with Germany for reciprocal protection of the minorities, as this might lead to interference by the Government of one country in the affairs of another. The Danish Government, however, offered the German minority every facility to develop its own culture, the school system of North Schleswig being reorganized with this view; parents decide whether they will have their children educated in German or Danish at primary schools, and German private schools receive State grants.

See Sach, *Geschichte der Stadt Schleswig* (Schleswig, 1875); and Jensen, *Schleswig und Umgebung* (Schleswig, 1905).

Bibliography.—The literature on the subject is vast. From the German point of view the most comprehensive treatment is in C. Jansen and K. Samwer, *Schleswig-Holsteins Befreiung* (Wiesbaden, 1897); *see* also H. C. L. von Sybel, *Foundation of the German Empire* (Eng. trans., New York, 1890–91); Bismarck's *Reflections and Reminiscences,* and L. Hahn, *Bismarck* (5 vols., 1878–91). The Danish point of view is ably and moderately presented in *La Question du Slesvig,* a collection of essays by various writers edited by F. de Jessen (Copenhagen, 1906), with maps and documents. (W. A. P.; X.)

SCHLETTSTADT: *see* Sélestat.

SCHLEY, WINFIELD SCOTT (1839–1911), American naval officer, was born at Richfields, near Frederick, Md., on Oct. 9, 1839. He graduated at the United States naval academy in 1860, and during the Civil War was in active service as a lieutenant until July 1863. In 1872–75 he was head of the department of modern languages in the U.S. naval academy. He was promoted commander in 1874; in 1876–79 commanded the "Essex," most of the time in the South Atlantic, and then until Oct. 1883 was inspector of the second lighthouse district. In Feb. 1884, Schley was appointed to command the third Greely relief expedition; and near Cape Sabine on June 22 rescued Greely and six companions. He commanded the "Baltimore" in Rear Admiral George Brown's squadron off the coast of Chile in 1891. He was commissioned commodore on Feb. 6, 1898, and was put in command of the "flying squadron," with the "Brooklyn" as his flagship, for service in the war with Spain. The command of the fleet off Santiago de Cuba was taken from Schley by Acting Rear Admiral W. T. Sampson. In the battle of Santiago on July 3, Schley, in Sampson's absence, was the senior officer. On Aug. 10, Schley was advanced six numbers and was made rear admiral for "eminent and conspicuous conduct in battle." When the Navy department recommended that Sampson be promoted eight numbers and over the head of Schley, who had ranked him for 42 years, there was a bitter controversy, and the Senate did not confirm the promotion. On April 14, 1899, Schley was commissioned rear admiral. In 1901 he retired from active service. At his request, because of the charges made against him in E. S. Maclay's *History of the Navy,* a court of inquiry investigated Schley's conduct before and during the battle of Santiago; in 1901 the court pronounced Schley guilty of delay in locating Cervera's squadron, of carelessness in endangering the "Texas" by a peculiar "loop" movement or turn of the "Brooklyn" which blanketed the fire of other American vessels, and of disobedience to a departmental order of May 25, but it recommended that no action be taken. He died in New York city, on Oct. 2, 1911.

Schley wrote, with James Russell Soley, *The Rescue of Greely* (1885). *See* Schley's *Forty-five Years under the Flag* (1904); "Admiral Schley's Own Story," *Cosmopolitan Magazine,* vol. lii. (1912); and James Parker, *Rear Admiral Schley, Sampson and Cervera* (1910).

SCHLICH, SIR WILLIAM, K.C.I.E., cr. 1909 (1840–1925), British forestry expert, was born at Darmstadt, Germany, on Feb. 28, 1840, and educated there and at the University of Giessen. In 1866 he entered the Indian Forests Department, became conservator of forests in 1871, and 10 years later inspector-general of forests to the Government of India. In 1886 he became a naturalized British subject. He was one of the pioneers of the study of forestry in England, organizing in 1885 the first school at Cooper's Hill, which was transferred to Oxford in 1905. He was appointed professor of forestry at Oxford the same year and retained the post until 1919. Among his books on the subject are: *A Manual of Forestry* (1889–95; new ed., 5 vol., 1925) and *Forestry in the United Kingdom* (1904). He died at Oxford on Sept. 28, 1925.

SCHLIEFFEN, ALFRED, Count von (1833–1913), Prussian soldier, was born on Feb. 28, 1833 in Berlin, of a Pomeranian family, the son of an army officer. He studied at Berlin University and the military academy and served in the war of 1866 against Austria and in that of 1870–71 against France as a general staff officer. In 1891 he was appointed chief of the general staff of the army. He held this position for 15 years, exercising an extraordinary influence on the development of the German general staff and the whole German army. He faced the problem of a war on two fronts, which would have to be waged with a single huge army. He promoted the training of general staff officers in the leading of huge armies, urged on technical equipment, and, finally, he threw all his energies into the effort to equip the army with mobile heavy artillery. He retired in 1907.

On his retirement Schlieffen put his views in writing. He is indeed far better known as an author than as chief of the general staff of the army. He was a disciple of Clausewitz, who in his turn had deduced his doctrine of strategy from Napoleon. Field-marshal von Moltke, whose successor and disciple Schlieffen was, had also based his ideas on Clausewitz, and it was the Napoleon-Moltke strategy that Schlieffen sought to carry on. The essence of their doctrine is that the enemy forces should be not merely defeated but destroyed. To this end it seemed to them necessary that not only the front but the flanks and if possible the rear should be attacked, so that the enemy should be forced to give battle on a reversed front. Schlieffen pushed this system to its logical conclusion. He saw Germany surrounded on all sides by enemies who, together, were far more powerful than herself. It seemed to him that the only salvation lay in opposing one of the enemies with a superior force, inflicting on him a decisive defeat, and then, using a well-developed network of railways and manoeuvring on inner lines, turning upon the other enemy against whom until then a defensive attitude would have been maintained. For this end rapidly decisive blows were needed and his writings aimed at proving such blows to be possible and showing how troops could be handled for that purpose.

With a marked singleness of purpose Schlieffen sought out the appropriate examples in military history and presented them in a new guise. His works are not military history in the accepted sense; he used military history to corroborate his doctrines. His books are definitely instructional. He watched the military-political situation of his own country, and feared, lest the grave hour should find, in the position he had had to leave, a man unequal to the overwhelming task. "A commander-in-chief must be inspired by something superhuman, something supernatural, call it genius or what you will."

Schlieffen died in Berlin on Jan. 4, 1913, but in 1914—seven years after his retirement—he still played his part in the world's history; for on retiring, he had bequeathed to his successor, General Moltke the younger, the plan for deployment against France. This plan embodies his strategic convictions. It is at

once immensely bold and also simple. Only the bare minimum was to remain facing the Russians; in the West the left flank was to be held back and the troops in Alsace were to withdraw behind the Rhine and face attack on the line Metz-Strasbourg. The bulk of the army was to deploy on the right flank and, pivoting on Metz, to drive forward against the line Dunkirk-Verdun. In this way the strongly fortified east front of France would be turned and the French army forced to give battle with a reversed front. Schlieffen intended not to give a recipe for victory, but to indicate the operative idea which, if logically carried out, would make possible the swift decision which alone could save Germany from her doom. The German army commander of 1914 considerably diluted the Schlieffen plan and, particularly in its execution, followed other courses than those pointed to by the dead strategist. And so it was that the inspired scheme of Schlieffen did not bear the fruits which were expected.

How armies are to be handled in the Schlieffen spirit the war on the Eastern front showed. The battle of Tannenberg has very justly been called a super-Cannae, and the campaign of Lodz, the German attack against the Warsaw-Thorn line—the best-conceived operation of the whole War, which was directed solely against the right flank of the Russians—rests upon Schlieffen's ideas. The field marshal's influence on the German leadership in the World War is incontestable, and his lifework cannot be ignored by anyone who intends to study the history of the World War. *See* Graf Schlieffen, *Gesammelte Schriften* (Berlin, 1913); *Cannae,* selection from the above (Berlin, 1925).

SCHLIEMANN, HEINRICH (1822–1890), German archaeologist, was born on Jan. 6, 1822 at Neu Buckow in Mecklenburg-Schwerin, the son of a poor pastor. He has stated in his autobiography that through all his early years of struggle, when he was successively grocer's apprentice at Fürstenberg, cabin-boy on the "Dorothea" bound for Venezuela, and, after her wreck, office attendant and then book-keeper in Amsterdam, he nourished a passion for the Homeric story and an ambition to become a great linguist. In the end, thanks to an unusually powerful memory and determined energy, he acquired a knowledge of seven or eight tongues besides his own, including ancient and modern Greek. The house of B. H. Schröder of Amsterdam sent him in 1846 to St. Petersburg, where he established a business of his own and embarked in the indigo trade. He made a fortune at the time of the Crimean War, partly as a military contractor. Happening to be in California when made a State of the Union, in 1850, he became and remained an American citizen. After travels in Greece, Tunisia, India, China and Japan, and writing a short sketch of the last two countries, he took his large fortune to Greece in 1868, and proceeded to visit Homeric sites. In an ensuing book—*Ithaka, der Peloponnes, und Troja*—he propounded two theories which he was destined eventually to test in practice, viz., that Hissarlik, not Bunarbashi, was the site of Troy, and that the Atreid graves, seen by Pausanias at Mycenae, lay within the citadel wall. Two years later he took up Calvert's work on the former site, and, convinced that Troy must be on the lowest level, hewed his way down, regardless of the upper strata, wherein lay unseen the remains of which he was really in search. By 1873 he had laid bare considerable fortifications and other remains of a burnt city of very great antiquity, and discovered a treasure of gold jewellery. We now know this city to have belonged to the middle pre-Mycenaean period, long prior to the generation of Homer's Archaeans, but Schliemann far and wide proclaimed it "Troy," and was backed by Gladstone and a large part of the European public. Trying to resume his work in February 1874, he found himself inhibited by the Ottoman government, whose allotted share of the gold treasure had not been satisfactory, and it was not till April 1876 that he obtained a *firman.* During the delay he issued his *Troy and its Remains* (1875), and betook himself to Mycenae. There in August 1876 he began work in the dome-tombs and by the Lion Gate, and opened a large pit just within the citadel. The famous double ring of slabs and certain stone reliefs came to light. Schliemann, thinking it was only a platform levelled as a place of Achaean assembly, paused, and did not resume till November. Then, resolved to explore to the rock, he cleared away some three feet more of earth and stones, and lighted on the five shaft graves which have placed him first among fortunate excavators. A sixth grave was found immediately after his departure. The immense treasure of gold, silver, bronze, fine stone and ivory objects, which was buried with the sixteen corpses in this circle, is worth intrinsically more than any treasure-trove known to have been found in any land, and it revealed once for all the character of a great civilization preceding the Hellenic. The find was deposited at Athens, and gradually cleaned and arranged in the Polytechnic; and the discoverer, publishing his *Mycenae* in English in 1877, had his full share of honours and fame. He had now settled in Athens, where he married a Greek lady, and built two splendid houses, which became centres of Athenian society. In 1878 he dug unsuccessfully in Ithaca, and in the same year and the following resumed work at Hissarlik, and summed up his results in a discursive memoir, *Ilios,* upon which a sequel, *Troja,* issued in 1884, after Wilhelm Dörpfeld, associated in 1882, had introduced some archaeological method into the explorations, was a considerable improvement.

In 1880 and 1881 Schliemann cleared out the ruined dome-tomb of Orchomenus, finding little except remains of its beautiful ceiling; and in 1885, with Dörpfeld, he laid bare the upper stratum on the rock of Tiryns, presenting scholars with a complete ground plan of a Mycenaean palace. This was his last fortunate excavation. While Tsountas, for the Greek Archaeological Society, picked up his work at Mycenae in 1886, and gradually cleared the Acropolis with notable results, Schliemann tried for traces of the Caesareum at Alexandria, of the Palace of Minos at Knossos, in Crete, and of the Aphrodite temple at Cythera (1888); but he was not successful, meeting in the two former enterprises with a local opposition which his wealth was unable to bear down. In 1889 he entertained at Hissarlik a committee of archaeological experts, deputed to examine Bötticher's absurd contention that the ruins represented not a city, but a cremation necropolis; and he was contemplating a new and more extensive campaign on the same site when, in December 1890, he was seized at Naples with an illness which ended fatally on the morning of Christmas Day. (D. G. H.)

SCHLIPPE'S SALT, or sodium thioantimoniate, named after K. F. Schlippe (1799–1867), is prepared by dissolving the calculated quantities of antimony trisulphide, sulphur and sodium hydroxide in water, and evaporating the liquid. The salt, $Na_3SbS_4 \cdot 9H_2O$, crystallizes in large tetrahedra, which are easily soluble in water, and have a specific gravity 1·806. The anhydrous salt melts easily when heated, and in the hydrated condition on exposure to moist air becomes coated with a red film. It combines with sodium thiosulphate to form $Na_3SbS_4 \cdot Na_2S_2O_3 \cdot 20H_2O$.

SCHLÖZER, AUGUST LUDWIG VON (1735–1809), German historian, was born at Gaggstedt, in the county of Hohenlohe-Kirchberg, on July 5, 1735. Having studied theology and oriental languages at the universities of Wittenberg and Göttingen, he went in 1755 as a tutor to Stockholm, and afterwards to Uppsala; and while in Sweden he wrote in Swedish an *Essay on the General History of Trade and of Seafaring in the most Ancient Times* (1758). In 1759 he returned to Göttingen, where he began the study of medicine. From 1761 to 1767 he occupied academic posts in Russia; he then returned to Göttingen, retired from active work in 1805, and died on Sept. 9, 1809.

Schlözer's most important works were his *Allgemeine nordische Geschichte,* 2 vols. (Halle, 1772) and his translation of the Russian chronicler Nestor to the year 980, 5 vols. (Göttingen, 1802–1809).

See Zermelo, *August Ludwig Schlözer* (Berlin, 1875); Wesendonck, *Die Begründung der neuern deutschen Geschichtsschreibung durch Gatterer und Schlözer* (Leipzig, 1876) and F. Frensdorff in *Allgemeine deutsche Biog.* vol. xxxi.

SCHLÜSSELBURG, a town of Russia in the Leningrad Area, in 59° 56′ N., 31° 3′ E., on marshy ground at the point

where the Neva river issues from Lake Ladoga. It has railway and steamer communication with Leningrad and there is a chintz factory. Pop. (1926) 6,317. Opposite the exit of the Neva are two islands, on the larger of which is a fortress, erected after its capture by the army of Peter the Great in 1702. It received its name because Peter considered it the key (Schlüssel) to the sea. After the final defeat of the Swedes in his reign, it was converted into a prison for political offenders, many of whom died as a result of the unhealthy conditions and severe régime. The first prisoners were the wife and daughter of Peter I., the latter of whom died here. Among other famous prisoners were Marshal Dolgoruki, Biron, the Tsar Ivan VI., many of the Dekabrists, the anarchist Bakunin, the Polish patriot Lukassinsky, who spent 37 years in prison and died here, and Lenin's brother, who was hanged here in 1887. Founded by the Novgorodians in 1323, it changed hands many times during the wars between Russia and Sweden, and after its re-capture by the Swedes in 1661 was called Noteborg.

See: *Guide to the Soviet Union* (Moscow, 1925).

SCHMALKALDEN, a town in the Prussian province of Hesse-Nassau, situated on the south-western slope of the Thuringian forest, 30 m. S.W. of Erfurt, on the railway Wernshausen-Zella. Pop. (1925) 10,402. Schmalkalden, which was first mentioned in 874, came wholly into the possession of Hesse in 1583, having been a town since 1335. It has a Gothic parish church, a palace—Schloss Wilhelmsburg—and a Gothic town hall in which the Protestant League of Schmalkalden was concluded in 1531, and also the house in which the articles of Schmalkalden were drawn up in 1537 by Luther, Melanchthon and other reformers. Its industries are chiefly connected with ironwares, but beer, soap and toys are also manufactured.

SCHMIDT, KARL VON (1817–1875), Prussian cavalry general, was born at Schwedt on the Oder, on Jan. 12, 1817, and entered the army in 1834. At the outbreak of the Franco-German War he was still an obscure and perhaps a mistrusted officer, though his grasp of every detail of cavalry work was admitted. But in the cavalry fighting around Mars-la-Tour (Aug. 16), he temporarily led a brigade and was severely wounded. Succeeding to the temporary command of his division on the disablement of its leader, he did brilliant work in the campaign on the Loire, and even in the winter operations towards Le Mans, and earned a reputation second to none amongst the officers and men of his army. After the war he took a leading part in the reorganization of the Prussian cavalry, which in ten years raised its efficiency to a level unexcelled by any other cavalry then in existence. He died at Danzig on Aug. 25, 1875.

SCHMIDT, WILHELM (1868–), Austrian philologist and Roman Catholic priest, was born at Hörde, Westphalia. He held the chair of primitive language and culture in the University of Vienna and devoted himself to the isolation and classification of the Austric family of languages (*see* PHILOLOGY).

SCHNEEBERG, a town of Germany, in the republic of Saxony, in the Erzgebirge, 14 m. S.E. from Zwickau by rail. Pop. (1925) 9,200. It contains a Gothic parish church, dedicated to St. Wolfgang, with an altar-piece by Lucas Cranach the elder, and a school of lace-making. Machine-made lace, embroidery, corsets, shoes and colours are among the chief of its industrial products.

SCHNEIDEMÜHL (Polish *Piła*), the capital town of the Prussian province of Grenzmark on the Cüddow, 60 m. N. of Posen and 145 m. N.E. of Berlin on the main line to Königsberg, and at the junction of lines to Stargard and Thorn. Pop. (1925) 37,507. Schneidemühl has a trade in wood, grain and potatoes, and possesses iron foundries, a brewery and machine-shops, and manufactures cement, starch and bricks. It is the seat of the provincial law courts.

SCHNITZLER, ARTHUR (1862–), Austrian playwright and novelist, was born in Vienna on May 15, 1862. He took a medical degree, and practised for a time as a physician. In 1908 he won the Grillparzer prize. Schnitzler's first and one of his most characteristic pieces was his *Anatol* (1893, Eng. trans. Granville Barker, 1911), a series of dramatic sketches of the love-adventures of a rich young Viennese. Nearly all Schnitzler's gifts are revealed in this series: a limpid style, a strong but never exaggerated sense of humour, an inimitably light touch, and above all, a gift of characterization second to none. Schnitzler understood the charming and frivolous Vienna of his day like no other writer, and his plays and stories are faultless reproductions of that life, so delightful within its limitations. Other plays in the same style are *Liebelei* (1895, Eng. trans. 1914) and *Freiwild* (1896), each striking a more tragic note in the fate of the "sweet little girl" round whom Viennese romance centres, and *Reigen,* a series of dialogues describing Viennese amours in such detail that, although written in 1900, it could only be performed in 1920. The best of his early stories are *Sterben* (1895), describing the decline of a consumptive, and *Leutnant Gustl* (1901), a monologue portraying the kindly but stupid soul of the Austrian subaltern with such deadly accuracy as to involve the author in some unpleasantness. As Schnitzler grew older, he approached his themes with added fervor but less lightness of touch. His one long novel *Der Weg ins Freie* revealed his limitations; limitations still more marked in his long romantic play *Der Junge Medardus* (1920). He continued, however, to produce short stories and plays whose perfection of style and characterization never flagged. Notable are the stories *Die Griechische Tänzerin* (1904), *Casanovas Heimfahrt* (1918, Eng. trans. E. and C. Paul, *Casanova's Homecoming,* 1922) and *Fräulein Else* (1924, Eng. trans. 1925), and the play *Professor Bernhardi* (1913). In his later period, Schnitzler at times left Vienna to deal with such subjects as the life and adventures of Casanova; but he remained happiest in describing his Viennese. His verse, while polished and brilliant, gives less scope to his talents than his prose. His collected works (1918) do not contain many later writings. Among his more recent works are *Beatrice* (Eng. trans. 1926); *Buch der Sprüche und Bedecken* (1927); and *Daybreak* (Eng. trans. 1928).

See J. Kapp *Arthur Schnitzler* (1912), and R. Specht, *Arthur Schnitzler* (1922). (C. A. M.)

SCHNORR VON KAROLSFELD, JULIUS (1794–1872), German painter, was born on March 26, 1794, at Leipzig, where he received his earliest instruction from his father Johann Veit Schnorr (1764–1841), a draughtsman, engraver and painter. At 17 he entered the Academy of Vienna, from which Overbeck and others who rebelled against the old conventional style had been expelled about a year before. In 1818 he followed the founders of the new school of German pre-Raphaelites in the general pilgrimage to Rome. This school of religious and romantic art abjured modern styles and set itself to recover fresco painting and "monumental art." Together with Cornelius, Overbeck and Veit, Schnorr received a commission to decorate the entrance hall of the Villa Massimo with frescoes after Ariosto. His second period dates from 1825, when he left Rome, settled in Munich, entered the service of King Ludwig, and transplanted to Germany the art of wall-painting learnt in Italy.

Schnorr's third period is marked by his "Bible Pictures" or Scripture History in 180 designs. The artist was a Lutheran, and took a broad and unsectarian view which won for his Pictorial Bible ready currency throughout Christendom. It does not, however, bear comparison with Raphael's Bible. Biblical drawings and cartoons for frescoes formed a natural prelude to designs for church windows. Schnorr made designs, carried out in the royal factory, Munich, for windows in Glasgow cathedral and in St. Paul's cathedral, London. He died on May 24, 1872.

SCHOBER, JOHANN (1874–), Austrian politician, was born and educated in Upper Austria, entering the Imperial Austrian police service as a young man, and became the Austrian president of police in 1918, some months before the revolution. On the proclamation of the Austrian republic (Nov. 12, 1918), Schober immediately placed his force at the disposal of the new Government, and by this action and by his moderate conduct in general did much to ensure a peaceful and bloodless change of régime. At the same time, he succeeded in securing the safety of the ex-Imperial family, whose departure from Vienna he supervised. During the two years of social democratic Government which followed, Schober's force was reproached by extremists with being reactionary, quite unjustly, as he aimed at strict

impartiality. His administrative ability, and above all, his conspicuous honesty, gained him the confidence of all moderate opinion in Austria, and especially of the inter-allied missions and advisers.

Largely because he was known to enjoy this confidence it was expected that if he were chancellor, the Allied and Associate Powers would be willing to grant the large loan necessary to restore Austria's chaotic finances, and he was selected to form a non-party ministry in June 1921. He took the first step towards establishing friendly relations between Austria and her neighbours when he concluded the pact of Lana with Czechoslovakia on Dec. 16, 1921 (*see* AUSTRIA). This move aroused the hostility of the pan-Germans, who formed a part of the Government coalition, and resented any pact with Czechoslovakia as putting difficulties in the way of the ultimate *Anschluss* with Germany. They withdrew from the Government coalition. The Christian Socialists were not strong enough to govern alone against the opposition of the Social Democrats. On May 24, 1922 Schober resigned the chancellorship and returned to the post of president of police.

SCHOBERT, JOHANN (*c.* 1720–1767), German composer and harpsichord player, was brought up at Strasbourg but settled in Paris in 1760, where he held an appointment under the Prince de Conti. He was one of the most popular players of the harpsichord of his time, and is praised by Mozart and by Grimm. He left a large number of agreeable "sonatas" for harpsichord, with and without the accompaniment of other instruments; also six "sinfonies" for clarinet and two horns. These were published and much played in London as well as in Paris. A selection is included in vol. xxxix., of *Denkmäler deutscher Tonkunst* (1909).

See also the article *Jean Schobert* by Georges de Saint-Foix in the *Revue musicale* of Aug. 1922.

SCHOFIELD, JOHN MCALLISTER (1831–1906), American soldier, was born at Gerry, Chautauqua county (N.Y.), on Sept. 29, 1831. He graduated at West Point in 1853, served for two years in the artillery, and was an assistant professor of philosophy at West Point in 1855–60. When the Civil War broke out he became a major in a Missouri volunteer regiment and served as chief of staff to Maj.-Gen. Nathaniel Lyon until the death of that officer. In 1864, as commander of the Army of the Ohio, he took part in the Atlanta campaign under Maj.-Gen. W. T. Sherman. In Oct. 1864 he was sent to Tennessee to join Maj.-Gen. G. H. Thomas in opposing Gen. J. B. Hood, and on Nov. 30 he fought with Gen. Hood the desperate indecisive battle of Franklin He was awarded the rank of brigadier-general (Nov. 1864) and the brevet rank of major-general (March, 1865) in the regular army. He co-operated with Sherman in North Carolina in the spring of 1865 with great skill and distinction.

After the war he was sent on a special diplomatic mission to France, on account of the presence of French troops in Mexico. From June 1868 to March 1869 he served as secretary of war under President Andrew Johnson, after the retirement of E. M. Stanton (*q.v.*). From 1876 to 1881 he was superintendent of the Military Academy at West Point, and from 1888 until his retirement in 1895 he was commanding general of the United States Army. He died at St. Augustine (Fla.) on March 4, 1906. Gen. Schofield published *Forty-Six years in the Army* (1897).

SCHOLASTICISM, the name usually employed to denote the most typical products of mediaeval thought, and commonly employed with differing shades of meaning down to modern times when its application has become fixed in accordance with the latest views of modern philosophy. These views are so far-reaching and complicated that the present article will be confined to an historical sketch of Scholasticism merely, and the reader is referred to the bibliography for details of modern publications on the subject.

After the centuries of intellectual darkness which followed upon the closing of the philosophical schools in Athens (529), and the death of Boetius, the last of the ancient philosophers, the first symptoms of renewed intellectual activity appear contemporaneously with the consolidation of the empire of the West in the hands of Charlemagne. He endeavoured to attract to his court the best scholars of Britain and Ireland, and by imperial decree (787) commanded the establishment of schools in connection with every abbey in his realms. Peter of Pisa and Alcuin of York were his advisers, and under their care the opposition long supposed to exist between godliness and secular learning speedily disappeared. Besides the celebrated school of the Palace, where Alcuin had among his hearers the members of the imperial family and the dignitaries of the empire as well as talented youths of humbler origin, we hear of the episcopal schools of Lyons, Orleans and St. Denis, the cloister schools of St. Martin of Tours, of Fulda, Corbie, Fontenelle and many others, besides the older monasteries of St. Gall and Reichenau. These schools became the centres of mediaeval learning and speculation, and from them the name Scholasticism is derived (*cf.* Sandys, *Hist. of Class. Schol.*, i. 471, 1906). They were designed to communicate instruction in the seven liberal arts which constituted the educational curriculum of the middle ages. (*See* TRIVIUM.) The name *doctor scholasticus* was applied originally to any teacher in such an ecclesiastical gymnasium, but gradually the study of dialectic or logic overshadowed the more elementary disciplines, and the general acceptation of "doctor" came to be one who occupied himself with the teaching of logic. The philosophy of the later Scholastics is more extended in its scope; but to the end of the mediaeval period philosophy centres in the discussion of the same logical problems which began to agitate the teachers of the 9th and 10th centuries.

Chronological Limits.—Scholasticism in the widest sense thus extends from the 9th to the end of the 14th or the beginning of the 15th century—from Erigena to Occam and his followers. The belated Scholastics who lingered beyond the last mentioned date served only as marks for the obloquy heaped upon the schools by the men of the new time. Erigena is really of the spiritual kindred of the Neoplatonists and Christian mystics rather than of the typical Scholastic doctors, and, in fact, the activity of Scholasticism is mainly confined within the limits of the 11th and the 14th centuries. It is divisible into two well-marked periods—the first extending to the end of the 12th century and embracing as its chief names Roscellinus, Anselm, William of Champeaux and Abélard, while the second extended from the beginning of the 13th century to the Renaissance and the general distraction of men's thoughts from the problems and methods of Scholasticism. In this second period the names of Albertus Magnus, Thomas Aquinas and Duns Scotus (*q.v.*) represent (in the 13th century and the first years of the 14th century) the culmination of Scholastic thought and its consolidation into system.

Prantl says that there is no such thing as philosophy in the middle ages; there are only logic and theology. The remark overlooks two facts—firstly that the main objects of theology and philosophy are identical, though the method of treatment is different, and secondly that logical discussion commonly leads up to metaphysical problems, and that this was pre-eminently the case with the logic of the Schoolmen. But the saying draws attention to the two great influences which shaped mediaeval thought—the tradition of ancient logic and the system of Christian theology. Scholasticism opens with a discussion of certain points in the Aristotelian logic; it speedily begins to apply its logical distinctions to the doctrines of the church; and when it attains its full stature in St. Thomas it has, with the exception of certain mysteries, rationalized or Aristotelianized the whole churchly system. Or we might say with equal truth that the philosophy of St. Thomas is Aristotle Christianized. The Schoolmen contemplate the universe of nature and man not with their own eyes but in the glass of Aristotelian formulae. Their chief works are in the shape of commentaries upon the writings of "the philosopher" (Aristotle). Their problems and solutions alike spring from the master's dicta—from the need of reconciling these with one another and with the conclusions of Christian theology.

Reason and Authority.—The fact that the channels of thought during the middle ages were determined in this way is usually expressed by saying that reason in the middle age is subject to authority. It has not the free play which characterizes its activity in Greece and in the philosophy of modern times. Its conclusions are predetermined, and the initiative of the individual

thinker is almost confined, therefore, to formal details in the treatment of his thesis. To the church, reason is the handmaid of faith (*ancilla fidei*). But this principle of the subordination of the reason wears a different aspect according to the century and writer referred to. In Scotus Erigena, at the beginning of the Scholastic era, there is no such subordination contemplated, because philosophy and theology in his work are in implicit unity. "Conficitur inde veram esse philosophiam veram religionem, conversimque veram religionem esse veram philosophiam" (*De divina praedestinatione*, Proem). Reason in its own strength and with its own instruments evolves a system of the universe which coincides, according to Erigena, with the teaching of Scripture. For Erigena, therefore, the speculative reason is the supreme arbiter; and in accordance with its results the utterances of Scripture and of the church have not infrequently to be subjected to an allegorical or mystical interpretation. But this is only to say again that Erigena is more of a Neoplatonist than a Scholastic. Hence Cousin suggested in respect of this point a threefold chronological division—at the outset the absolute subordination of philosophy to theology, then the period of their alliance, and finally the beginning of their separation. In other words, we note philosophy gradually extending its claims. Dialectic is, to begin with, a merely secular art, and only by degrees are its terms and distinctions applied to the subject-matter of theology. The early results of the application, in the hands of Berengarius and Roscellinus, did not seem favourable to Christian orthodoxy. Hence the strength with which a champion of the faith like Anselm insists on the subordination of reason. To Bernard of Clairvaux and many other churchmen the application of dialectic to the things of faith appears as dangerous as it is impious. Later, in the systems of the great Schoolmen, the rights of reason are fully established and acknowledged. The relation of reason and faith remains external, and certain doctrines—an increasing number as time goes on—are withdrawn from the sphere of reason. But with these exceptions the two march side by side; they establish by different means the same results. For the conflicts which accompanied the first intrusion of philosophy into the theological domain more profound and cautious thinkers with a far ampler apparatus of knowledge had substituted a harmony. "The constant effort of Scholasticism to be at once philosophy and theology" seemed at last satisfactorily realized. But the further progress of Scholastic thought consisted in a withdrawal of doctrine after doctrine from the possibility of rational proof and their relegation to the sphere of faith. Indeed, no sooner was the harmony apparently established by Aquinas than Duns Scotus began this negative criticism, which is carried much farther by William of Occam. But this is equivalent to a confession that Scholasticism had failed in its task, which was to rationalize the doctrines of the church. The Aristotelian form refused to fit a matter for which it was never intended; the matter of Christian theology refused to be forced into an alien form. The end of the period was thus brought about by the internal decay of its method and principles quite as much as by the variety of external causes which contributed to transfer men's interests to other subjects.

Bibliography.—Besides the numerous works quoted in articles on the individual philosophers, *see* Hauréau, *Histoire de la philosophie scolastique* (2 vols., 1850; revised and expanded in 1870 as *Histoire de la phil. scol.*), Kaulich, *Geschichte d. schol. Philosophie* (1863); Stöckl, *Gesch. der Phil. des Mittelalters* (3 vols., 1864–66); Karl Werner, *Die Scholastik des späteren Mittelalters* (4 vols., 1881–87); and, on a smaller scale, de Wulf's *Histoire de la phil. médiévale* (1900; 5th ed., 1924–25). Supplementary details are given in Hauréau's *Singularités historiques et littéraires* (1861) and in R. L. Poole's *Illustrations of the History of Mediaeval Thought* (1884), while much light is thrown upon the minuter history of the period by the *Chartularium Universitatis Parisiensis* edited by Denifle and Chatelain in 1894, by Hauréau's *Notices et extraits de quelques MS. latins de la Bibliothèque Nationale* (6 vols., 1890–1895) and by the *Beiträge zur Geschichte d. Phil. d. Mittelalters*. The accounts of mediaeval thought by Ritter, Erdmann, Ueberweg and Windelband are very good. There are also notices of the leading systems in Milman's *History of Latin Christianity* (6 vols., 1854–55). The psychology of the Scholastic writers is ably dealt with in Siebeck's *Die Psychologie von Aristoteles bis zu Thomas von Aquino* (1885). Jourdain's *Recherches critiques sur l'âge et l'origine des traductions latines d'Aristote* (1819; 2nd ed. 1843); Rousselot's *Études sur la philosophie dans le moyen âge* (1840–1842), Cousin's Introduction to his *Ouvrages inédits d'Abélard* (1836), and Prantl's *Geschichte der Logik im Abendlande* (4 vols., 1855–1870) are invaluable aids in studying the history of mediaeval thought. For modern views *see* C. Baeumker, *Abhandlungen zur Geschichte der Philosophie des Mittelalters* (1923); G. Ritter, *Studien zur Spätscholastik* (1921, etc.); A. C. A. Schneider, *Die Erkenntnislehre bei Beginn der Scholastik* (1921); H. O. Taylor, *The Mediaeval Mind*, 2 vols. (1925); O. Wichmann, *Die Scholastiker* (1921); N. de Wulf, *Histoire de la philosophie médiévale* (1924, etc.).

SCHOLIUM (to be distinguished from *Scolium*, an after-dinner song), the name given to grammatical, critical and explanatory notes, extracted from existing commentaries and inserted on the margin of the m.s. of an ancient author. These notes were altered by successive copyists and owners of the m.s. and in some cases increased to such an extent that there was no longer room for them in the margin, and it became necessary to make them into a separate work. The name of "the first scholiast" has been given to Didymus of Alexandria (*q.v.*), and the practice of compiling scholia continued till the 15th or 16th century A.D. The word σχόλιον itself is first met with in Cicero (*Ad Att.* xvi. 7). The Greek scholia we possess are for the most part anonymous, the commentaries of Eustathius on Homer and Tzetzes on Lycophron being exceptions. Although frequently trifling, they contain much information not found elsewhere, and are of use for the correction and interpretation of the text. The most important are those on Homer (especially the Venetian scholia on the *Iliad*, discovered by Villoison in 1781 in the library of St. Mark), Hesiod, Pindar, Sophocles, Aristophanes and Apollonius Rhodius; and, in Latin, those of Servius on Virgil, of Acro and Porphyrio on Horace, and of Donatus on Terence.

SCHOMBERG, FRIEDRICH HERMANN (or Frederic Armand), Duke of (*c.* 1615–1690), marshal of France and English general, was born in Dec. 1615 or Jan. 1616, at Heidelberg, the son of Hans Meinard von Schönberg (1582–1616) and Anne Sutton, daughter of the 9th Lord Dudley. He was educated by various friends, among whom was the "Winter King," Frederick V. of the Palatinate, in whose service his father had been. He began his military career under Frederick Henry, prince of Orange, and passed about 1634 into the Swedish service, whence he entered that of France in 1635. After a time he retired to his family estate at Geisenheim on the Rhine, but in 1639 he re-entered the Dutch army, in which he remained until about 1650. He then rejoined the French army as a general officer (*maréchal de camp*), served under Turenne in the campaigns against Condé, and became a lieutenant-general in 1665.

After the peace of the Pyrenees (1659) the independence of Portugal being again menaced by Spain, Schomberg was sent as military adviser to Lisbon with the secret approval of Charles II. of England and Louis XIV., who in order not to infringe the treaty just made with Spain, deprived Schomberg of his French offices. Schomberg won the victory of Montes Claros on June 17, 1665 over the Spaniards under the prince of Parma. He helped to depose the reigning king in favour of his brother Dom Pedro, and then returned to France, became a naturalized Frenchman and bought the lordship of Coubert near Paris. In 1673 he was invited by Charles to England to command the army, but sentiment was so strong against the appointment, as savouring of French influence, that it was not carried into effect. He again entered the service of France. His first operations in Catalonia were unsuccessful owing to the disobedience of subordinates and the rawness of his troops, but he retrieved the failure of 1674 by retaking Bellegarde in 1675. For this he was made a marshal, being included in the promotion that followed the death of Turenne.

The tide had now set against the Huguenots, and Schomberg's merits had been long ignored on account of his Protestantism. The revocation of the edict of Nantes (1685) compelled him to quit France, and he became general-in-chief of the forces of the elector of Brandenburg; at Berlin he was the acknowledged leader of the Huguenot refugees.

Soon afterwards, with the elector's consent, he joined the prince of Orange on his expedition to England in 1688, as second in

command to the prince. The following year he was made a knight of the Garter, was created successively baron, marquis and duke, was appointed master-general of the ordnance, and received compensation for the loss of his French estates, of which Louis had deprived him. In August he commanded the expedition to Ireland against James II. After capturing Carrickfergus he marched unopposed through a country desolated before him to Dundalk, but decided not to risk a battle with his undisciplined troops, and entrenching himself at Dundalk declined to be drawn beyond the circle of his defences. Shortly afterwards pestilence broke out, and when he retired to winter quarters in Ulster his forces were severely shattered. His conduct was criticized in ill-informed quarters, but the facts justified his inactivity. In the spring he began the campaign with the capture of Charlemont, but no advance southward was made until the arrival of William. At the Boyne (July 1, 1690) Schomberg gave his opinion against the determination of William to cross the river in face of the opposing army. In the battle he commanded the centre, and while riding through the river without his cuirass to rally his men, was surrounded by Irish horsemen and instantly killed. He was buried in St. Patrick's cathedral, Dublin.

His eldest son Charles, the second duke in the English peerage, died in 1693 of wounds received at the battle of Marsaglia.

The most important work on Schomberg's life and career is Kazner's *Leben Friedrichs von Schomberg oder Schönberg* (Mannheim, 1789). The military histories and memoirs of the time should also be consulted.

SCHOMBURGK, SIR ROBERT HERMANN (1804–1865), British traveller, was born at Freiburg, Prussian Saxony, on June 5, 1804, the son of a Protestant minister. In 1829 he went to the United States and in 1830 to Anegada, one of the Virgin Isles. He surveyed the island at his own expense. In 1835 he was entrusted by the Royal Geographical Society with the conduct of an exploring expedition to British Guiana, in the course of which he discovered the Victoria Regia lily. In 1841 he returned to Guiana to survey the colony and fix the boundary, which was known as the "Schomburgk Line." (*See* British Guiana and Venezuela.) On his return to England he was knighted. In 1848 he was appointed British consul to St. Domingo, and, in 1857, British consul to Bangkok, meanwhile continuing his geographical surveys. He retired from the public service in 1864, and died at Berlin on March 11, 1865. He wrote *Description of British Guiana* and a *History of Barbados.*

SCHÖNBEIN, CHRISTIAN FRIEDRICH (1799–1868), German chemist, was born at Metzingen, Swabia, on Oct. 18, 1799, and died at Sauersberg, near Baden Baden, on Aug. 29, 1868. After studying at Tübingen and Erlangen, he taught chemistry and physics, first at Keilhau, Thuringia, and then at Epsom, England, but most of his life was spent at Basel, where he began to lecture on chemistry and physics in 1828 and was appointed full professor in 1835. His name is chiefly known in connection with ozone (*q.v.*), which he discovered in 1840, and with guncotton (*see* Explosives), which he prepared and applied as a propellant in fire-arms early in 1846. He also worked on the passivity of iron, the properties of hydrogen peroxide and catalysis. He was a most prolific writer, 364 papers appearing under his name in the Royal Society's *Catalogue.*

Many of his letters together with a life will be found in G. W. A. Kahlbaum's *Monographien aus der Geschichte der Chemie,* vols. iv. and vi. (1899 and 1901).

SCHÖNBERG, ARNOLD (1874–), Austrian composer, was born in Vienna on Sept. 13, 1874. He began to study violin and 'cello at an early age and to compose chamber music. In musical theory he was practically self-taught. His earlier works include songs, the string sextet, *Verklärte Nacht* op. 4 (revised later for string orchestra with six soloists), the symphonic poem, *Pelléas et Mélisande,* and the *Gurrelieder,* a ballad cycle for chorus and full orchestra (first produced in Vienna 1912–3), written under the influence of the Wagner tradition. Schönberg then came into touch with Kokoschka and other leaders of the new movement in art and literature, and entered upon an experimental period in which he put romanticism behind him and went back to Bach and the earlier polyphonic writers for inspiration. With the 2nd chamber symphony and particularly the 2nd string quartet (1908), into the last two movements of which he introduces a soprano part to words by Stephan George, he definitely breaks away from tradition; and with the piano pieces op. 11 his mature period may be said to begin, although he continues to strike out new paths with each successive work. In 1911 he went to live in Berlin and in the same year produced his *Harmonielehre* (*see* Harmony), a revised edition of which was published in 1922.

An eventful performance was that of *Pierrot Lunaire* in Berlin the following year with Albertine Zehme in the spoken part. This cycle of twenty-one ("three times seven") poems for recitation with piano, flute, clarinet, violin, and violoncello in constantly changing combinations, is, after the *Gurrelieder,* his best known work. In 1918, having returned to Vienna, Schönberg founded there a society for private musical performances. A revival of *Die glückliche Hand* op. 18 at Breslau in 1928 aroused much interest. This dramatic piece, which is in effect a monodrama, with dumb secondary characters and a chorus, is in spite of its early date perhaps the most daring of Schönberg's experiments and that in which his psychology finds its clearest expression. He both wrote the libretto and ordered every detail of the staging. Essentially a pioneer, he has never made concessions to the ordinary listener, but the tenseness and extreme compression of this work make quite unprecedented demands on the concentrative powers of his audiences. In all his later writing the combination of a tersely dramatic and fragmentary style with complete atonality leaves an impression of complication and strain: he is nevertheless sincerely striving towards simplicity and compactness, and his reversion to a smaller or chamber orchestra has led to a general adoption of this medium by younger composers. He has also adopted a simplified method of scoring, in which duplication of parts is avoided and the whole is compressed on to a few staves.

Other important works are: 6 songs with orchestra op. 8 (1911); chamber symphony for 15 solo instr. op. 9 (1912); *Melodramen* op. 21; serenade for clarinet, bass clarinet, mandoline, guitar, three strings and (low) male voice op. 24 (1924); pianoforte suite op. 25; quintet for wind instr. op. 26. *See* E. Wellesz, *Arnold Schönberg* (1924); Paul Bekker, *Kritische Zeitbilder* (1921).

SCHÖNEBECK, a town of Germany, in the province of Prussian Saxony, on the left bank of the Elbe, 9 m. S. of Magdeburg by the railway to Halle and Leipzig. Pop. (1925) 21,409. It contains manufactories of chemicals, machinery, bicycles, rubber, explosives and various other articles, but is chiefly noted for its extensive salt works. There is a harbour on the Elbe here, and a brisk trade is carried on in coal, grain and timber.

SCHÖNEBERG, a suburb of Berlin, Germany, which it adjoins on the south-west. Pop. (1925) 239,042. The foundation of Alt-Schöneberg is ascribed to Albert the Bear, margrave of Brandenburg, in the 12th century, while Neu-Schöneberg was founded by Frederick the Great in 1750 to accommodate some Bohemian weavers exiled for their religion. Its chief manufactures are railway material, cigars, soap, paper and chemicals.

SCHONGAUER (or Shön), **MARTIN** (*c.* 1445–1491), engraver and painter of the early German school. His father was a goldsmith named Caspar, a native of Augsburg, who had settled at Colmar, where the chief part of Martin's life was spent. Schongauer established at Colmar a very important school of engraving, out of which grew the "little masters" of the succeeding generation, and a large group of Nuremberg artists. As a painter, Schongauer was a follower of the Flemish Roger van der Weyden, and his painting closely resembles both in splendour of colour and exquisite minuteness of execution, the best works of contemporary art in Flanders. The only picture which can with certainty be attributed to him, is a magnificent altar-piece in the church of St. Martin at Colmar, dated 1473, representing the Virgin and Child before a hedge of roses. Schongauer was the first painter who was also an engraver, and his work contributed much to the development of engraving. He produced a large number of beautiful engravings, which were largely sold, not only in Germany, but also in Italy, England, France and Spain. His subjects are always religious; 113 prints from copper by his hand

are known; they are signed with his monogram M+S. Among the most beautiful of Schongauer's engravings are the series of the "Passion" and the "Death and Coronation of the Virgin," and the series of the "Wise and Foolish Virgins." All are remarkable for their treatment of line, their brilliant touch, and their chromatic force. Some, such as the "Death of the Virgin" and the "Adoration of the Magi" are richly-filled compositions of many figures, treated with much largeness of style in spite of their minute scale. He died in Breisach in 1491.

The British Museum possesses a fine collection of Schongauer's prints. Fine facsimiles of his engravings have been produced by Armand-Durand with text by Duplessis (Paris, 1881).

SCHÖNHERR, KARL (1867–), Austrian dramatist, was born at Axams, Tyrol, Feb. 24, 1867. He first wrote dialect poems of an unassuming nature and short stories, but in 1897 he turned his attention to drama and the stage with the *Judas von Tirol,* which he remodelled in 1927. Schönherr stood midway between realism and symbolism and expressed himself in a vigorous and original style. His accomplished technique, applied frequently to peasant or medical life, enabled him to evolve successful dramas with a very limited number of characters. In his pieces, quite elementary and simple emotions and the problems and crises arising out of them are presented with inexorable consistency. His most famous drama, *Glaube und Heimat* (1910), dealing with the time of the Counter-Reformation, and also *Der Weibsteufel* (1915) have aroused religious controversy. Schönherr's other important works include *Die Bildschnitzer* (1900); *Erde* (1908); *Volk in Not* (1915); *Frau Suitner* (1916); *Vivat academia* (1922); *Es* (1923); *Hungerblockade* (1925). Most of his dramas were first produced in the Burgtheater and in the Deutsches Volkstheater in Vienna. His tales and sketches, *Caritas* and *Aus meinem Merkbuch,* express much the same trend of thought and motif as his dramas. He won the Schiller Prize in 1908 and the Grillparzer Prize in 1911, 1917, and 1920. His *Gesammelte Werke* began to appear in 1927. *See* monographs by Sedlmaier (1920), Lederer (1925), and Bettelheim (1927).

SCHOOL ADMINISTRATION IN THE UNITED STATES differs from that in most other nations in that it is less centralized. While it is common to speak of the American public school system, legally at least there is no such organization. Education in the United States, in all its branches, and from kindergarten to university, has been left by the Federal Constitution to the different States to provide and manage as they see fit. There is no national legislation relating to the subject, aside from that concerning the Federal aid granted to the States for certain specific purposes. One finds in the city of Washington a U.S. commissioner of education, appointed by the President and confirmed by the Senate, who has a small office force, collects statistics as to the progress of education in the States and in other lands, answers inquiries and offers advice when asked to do so, but in reality an officer without power, even within the Federal district. Each State is responsible for the maintenance of a State system of public instruction. Still more, due to the large liberty in matters of instruction and control allowed counties, cities, towns and districts within the different States, there are wide variations in the schools maintained by the different local governing school boards. School administration then divides itself into three main headings—State, county and city.

State School Administration.—Throughout all the history of the relations of the Federal Government to the States, in the matter of public education, Congress, since the beginning of the nation under the Federal Constitution, in 1789, has dealt entirely with the governments of the States. Each of the States has in turn developed a State school system, and in time has built up a body of legislative enactments relating to education known as the State School Law, or the State School Code. Dealing at first with only the essential outlines of a school system, and elementary rather than secondary education, the school law for each of the States has, since the '90s, experienced a marked development and expansion. As a result one finds to-day, for each of the States, a large and important body of laws—naturally more detailed in some States than in others—relating to the organization, administration, supervision and financing of a complete system of public instruction for the State.

The management of the schools of any city or school district within a State may be placed by law in the hands of locally-elected school officers, and much liberty of action may be granted to these local officials by the State school code, but the schools nevertheless exist to carry out a State purpose, as expressed in the State Constitution and the State school law. The local governing authorities act as agents for the State and can do only those things which the school law permits. Throughout all the educational history of America it has been the State that has ordered that children shall be educated, advantages extended, standards raised and taxation for education increased.

As the chief representative of each State school system one finds an appointed or in a few cases an elected State board of education, and an elected or an appointed State superintendent of public instruction or State commissioner of education. The plan followed in approximately one-fourth of the States is the appointment of a lay State board of education of from seven to nine members, for relatively long terms, to act as a legislative control and policy-determining body for the school system of the State, and for this board then to select and appoint a State commissioner of education to act as its chief executive officer.

The State board of education in the best organized States acts in the name of the State as a board for general control of the State school system in its larger aspects, and for the enforcement of the provisions of the State school law. It selects, on the recommendation of its chief executive officer, educational experts to exercise supervisory administrative control over the different divisions of the State school system—elementary schools, secondary schools, child welfare, vocational education, school buildings, etc.; exercises general oversight of the work in vocational education and vocational rehabilitation, maintained in part by Federal aid grants; often controls in large part the training and certification of teachers; determines the broad educational policies to be pursued by the State; and enacts rules and regulations for the government of its executive officers and, to a limited extent, the schools of the State as well. Such a board of control is primarily a legislative body, leaving the execution of policies and the carrying out of decisions arrived at to the executive officers it employs.

County and Local Administration.—The county is used more or less everywhere as a unit for school administration, except in the New England States. The town in New England and the analogous township in the North Central States also are used as units for school administrative control. The city as a unit is found everywhere, and the school district, in the sense of a small rural area under the control of an elected board of three local school trustees, is found by the thousands in approximately three-fourths of the States. Long experience has demonstrated the inefficiency and wastefulness of the little school district, and the tendency everywhere is to limit their powers and to abolish them for some larger unit of school control. Approximately one-fourth of the States have already made this transition, and have only county and city school districts beneath the State, while another fourth of the States have made important progress in this direction. The ultimate outcome of the process is that the State, for subordinate administrative control, becomes organized into only as many school districts as there are counties and cities in the State, with each county and each city under a separate representative board for school control. In a very few of the States the city has even been made a part of the county organization. For each county and each city the people then elect a small lay board of education, which in turn elects its own executive officer—county or city superintendent of schools—and exercises control over the schools in its jurisdiction as required by the State school law and the rules and regulations of the State board of education. The result of such a transformation, where effected, has been to abolish thousands of little independent school districts, and to

substitute in their stead from 25 to 100 county school districts, and an approximately equal number of city school districts. One classification then provides for the education of rural and village children, and the other for the education of the children who live in cities.

With the reorganization of all the district and village schools of a county into one county unit for educational administration, supervision and finance; the election by the people of one lay county board of education to select the educational experts and to determine the larger questions of policy and educational procedure for the schools of the county; and the reorganization and redirection of rural and village education so as to meet modern educational needs, with independent organization for the cities only because of their size and the diversity of their educational problems, an efficient State educational system is being evolved. The school affairs of any large commonwealth have grown into a large and very important business undertaking, costing the people millions of dollars each year, and the direction of this business is being placed under a form of administration dictated by the best American experience in educational and corporation control. The form of subordinate educational organization, then, which any State has evolved determines, to a large extent, the effectiveness of the educational system it maintains.

Major State Administrative Problems.—The present tendency is toward a centralization of administration, with a more or less clear demarcation between State and *locus* powers and duties in matters of school control. In such matters as statistical and financial returns State uniformity naturally is to be prescribed. In all such matters as minimum length of term, types of schools to be maintained, sanitary standards, maximum rates for taxation for school support, standards for the training and certification of teachers, minimum salary laws, compulsory attendance and child-labour laws, it is clearly the duty of the State to determine the minimum standards which shall be permitted. Still more, from time to time, as changing needs and conditions may seem to require, it is clearly the duty of the State to raise these minima. To do these things successfully involves a carefully thought out educational policy which looks to a series of progressive changes and the securing of results over a period of time.

In carrying out a constructive State educational policy a number of distinctively State educational problems call for careful consideration. These group themselves about the nature and extent of State oversight and control; the proper division of powers and functions, as between the State and its subordinate units; the provision of adequate professional supervision for all schools; the best subordinate unit or units for local administration; proper methods in taxation for education, and the apportionment of school funds; the scope of the educational system to be maintained; the large social and educational problems surrounding rural and village education; vocational training; part-time, extension, and adult education; the material equipment of schools; health and sanitary control; the training of teachers, both before and after beginning service; salary schedules, tenure and pensions; the protection of the child; and the relation of the State to non-State educational agencies.

City School Administration.—A wholly different set of educational problems relate to school organization and administration in the cities. These relate to the grading of schools, instruction of special classes, playgrounds and vacation schools, kindergartens and pre-school training, schools for delinquents, compulsory education, health work in the schools, vocational instruction and guidance, business organization, school plant, professional supervision and similar matters. Practically everywhere in cities the schools, while regarded as State schools in theory and under the provisions of the general State school law, are for control placed under the immediate oversight of a local school board, generally known as the board of education. Standard procedures have been established which are quite generally followed, namely: that the superintendent of city schools shall be the recognized executive officer of the board of education, responsible to it for the proper carrying on of the school business of the city; that the board shall legislate, and the superintendent and his staff shall execute; that the superintendent shall be in immediate charge of the educational department, but with supervisory oversight of all other department heads; and that the initiative in all such matters as the determination of the courses of study, the selection of text-books and teaching supplies, the nomination and placement of teachers, the supervision of the instruction, the progress of pupils in the schools, and the determination of records to be kept and reports to be made shall rest with the superintendent of schools.

A distinctive feature of city school systems, and one that has made them an interesting object of study to students of educational administration coming from other lands, is the wide diversity in educational facilities which they provide, with a resulting adaptability of the instruction to the needs of the many different classes in the population which attend. Unlike most European two-class school systems, the American public school has been compelled to organize its instruction about a one-track form of educational organization and provide an educational ladder nominally at least open to all. The adjustment to the needs of the different social and intellectual classes which attend has had to be made by providing a diversity of types of classes and instruction. This adaptability has been made possible only by reason of the unity of its administration and finance, and it could not have been provided except under a centralized large-scale form of educational organization.

In business administration and finance, the city school district has long enjoyed exceptional advantages. As a part of the State educational organization, the cities share in any apportionment of State school funds and taxes made. In the rate of taxation which must be levied locally or degree of support which must be provided, the State has set the limits rather than the local city governing authorities. In addition, due to the concentration of wealth which the city usually represents, and with local school levies made on the city school district as a whole by one administrative board, a pooling of costs is made possible which results in the provision of uniform educational advantages for all without undue burden to any portion of the whole.

In practice, city boards of education determine their own expenditures, within limits set by the State school law, in approximately three-fourths of the cities of the United States, and in the remaining cities they formulate their budget but are dependent on the city council for allotment of the amount they may have to spend, after the State minimum requirements have been met. In the United States as a whole, approximately 20% of all money expended comes from State sources, approximately 15% from county sources and the remaining 65% is levied locally, though with wide variations in these proportions in the different States. Approximately 25% of the total taxes levied for all purposes in cities is devoted to the maintenance of schools, with extremes as low as 10% and as high as 40%. For school administration in other countries *see* EDUCATION.

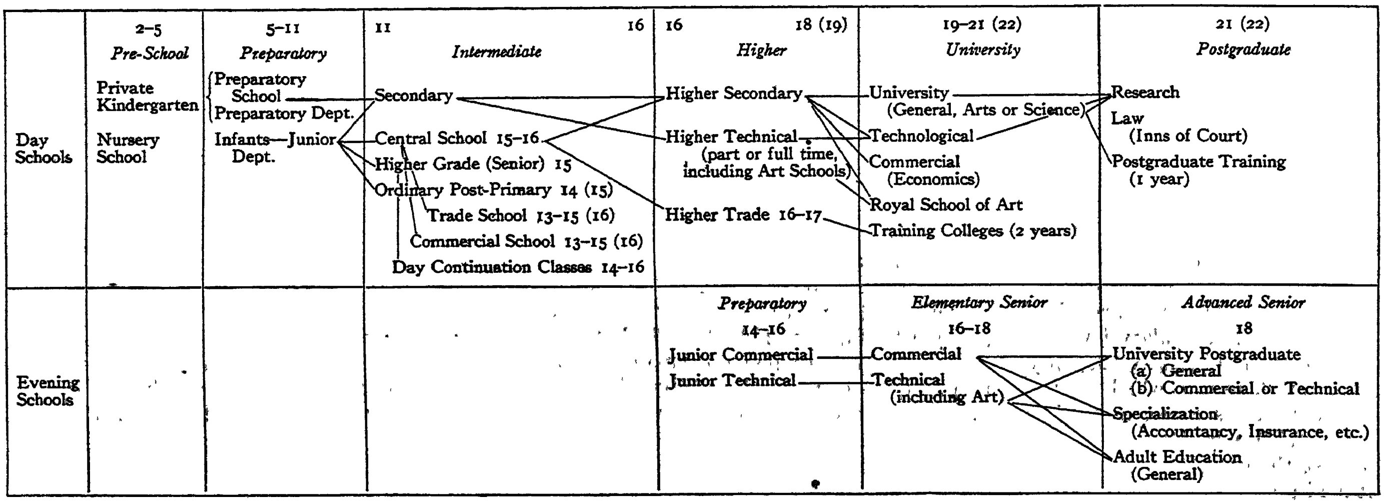
SCHOOL AND CURRICULUM. A curriculum is a course of study laid down for the students of a university or school, or, in a wider sense, for schools of a certain standard, *e.g.*, secondary, elementary, etc. (Lat. *curriculum,* a course).

GREAT BRITAIN

Secondary School.—The beginnings of the present curriculum in English secondary schools are to be sought in that of the "Public Schools" which during the 18th and the early part of the 19th century was practically confined to Latin and Greek, even the grammar of both languages being taught through the medium of action. Classics in fact were held to provide the complete outfit for the education of the scholar and gentleman that it was the ideal of the school to produce. The girls' schools (*see* WOMEN, EDUCATION OF) as they grew and multiplied helped by their example to accelerate the introduction of more modern subjects. But each subject, whether science, history or the like, had so to

say, to fight its way in the curriculum as something that was *per se* desirable from the standpoint of general education. The rapid growth of the municipal and county secondary schools after 1902 gave a further impetus to the modern side of education already recognized in the public schools. None the less the idea of a scientific curriculum as a whole composed of carefully selected ingredients with a clear objective in view in place of a conglomeration of supposed indispensable subjects has been very slow in making its way in Great Britain. Almost equally tardy has been the recognition of the vital principle that the curriculum exists for the average pupil and not the average pupil for the curriculum, with its corollary that the inclusion of this or that subject is not to be decided by its supposed intrinsic value alone, but either by the duration of the educational life of the pupil or by the nature of his future vocation. Every complete type of education should have a sound basis of general culture with some degree of specialization at the top. How far this is being realized in England may be seen from the table given below:



Elementary Schools.—During the 19th century up to 1870 and even later, reading, writing and arithmetic, and cooking and needlework for girls were considered to be the end all and be all of elementary education. Later, science found its way into the higher departments not so much on its merits as from the financial advantages it offered to the school Boards of earning additional grants from the Science and Art department. Other subjects like history and geography being less remunerative came in much more slowly. The abolition of payment by results conferred a welcome elasticity on the curriculum, possibly in some cases an excessive one. But the introduction of definite curricula for the central schools has effected a steadying influence and with the gradual putting into effect of the Hadow report (*see* ELEMENTARY EDUCATION) involving a definite break in the education of boys at the age of 11, the growing ideal of education being for livelihood as well as life is bound to be reinforced, while any undue diffusion of effort that may have existed in the past by the attempt to embrace too many subjects is likely to disappear. At the same time the hitherto slow differentiation of the curriculum to suit different localities and their needs (*see* EDUCATION AND INDUSTRY) will receive a much needed momentum. This is especially a matter of great importance in rural districts (*see* RURAL EDUCATION), where the curriculum until recently has been moulded much too closely on that of the town schools. For a forecast of the future development of a differentiation of the curriculum on still broader lines (*see* B. Branford's *Janus and Vesta*, chap. x.), which deals among other things with the still excessive subdivision of the curriculum into subjects and their regrouping in larger units.

Broadly speaking, the teaching in all subjects during the last 30 years both in secondary and elementary schools has undergone a change at once vast and beneficial. Originally it was predominantly *intensive*, the idea being to study a little, but to study it well (*non multa sed multum*), a premium being placed on the cultivation of the memory. To-day it has become largely *extensive*, the aim being rather to cover as much ground as possible and cultivate the reason and imagination of the pupil. Possibly in some subjects the insufficient stress laid on the acquisition of technique has gone too far. Recent psychological research in America has been re-establishing the claims of habit-forming and memory. Already one may note in some subjects the harking back to some extent to older methods whether it be the memorizing of dates (history), or of place names (geography), or of grammatical forms (modern languages) or of accuracy and the mastery of numerical manipulations (arithmetic). In any case to English teachers whose teaching has also been based on experimenting by trial and error, the necessary adjustments should not prove difficult. (*See* EDUCATION.) (C. BR.)

The Mother-tongue.—There is nothing so paradoxical in the history of education in England as the insignificant part that till recently the teaching of the mother-tongue has occupied in the schools. There has been a remarkable conspiracy of circumstances to prevent it from taking its right place. The Norman conquest drove English for a considerable time underground.

But the mother-tongue had another more powerful rival. During the middle ages Latin was the international language, used by the theologian, the diplomatist, and the scholar. It was, however, Latin in a debased form, despised by the humanists of the Renaissance. They had noble ideals of culture and education based upon the recovered classical masterpieces, but the only pathway to these was through the grammars of the ancient tongues, especially Latin. A few voices like those of Mulcaster and Locke were raised on behalf of English in the schools.

But, in the main, the classical system in the degenerate form of "grammatic flats and shallows," kept its hold throughout the 18th and 19th centuries. This had important and besides, for the most part, unfortunate consequences for popular education in England, which began its systematic development after the Reform Bill (1832). It was inevitable that in any form of State-controlled education for the mass of the population, English should be the basis. But the statesmen and officials who organized the system, and who drew up the curricula of the training colleges for teachers had been, as a rule, educated on the prevalent and narrow type of humanism which substituted linguistic for literary study. They therefore encouraged the teaching of English in the elementary schools on the same formal lines as Greek and Latin were being taught in the higher stages. Thus English in the elementary school meant little more than grammar, and this, in its turn, meant chiefly analysis and parsing. Literature had scarcely any place in the curriculum.

From the opening of the present century a number of circumstances have combined to produce what may be called a new renaissance of English in the schools. The acts of 1902 and 1903 brought for the first time the different stages of English education into close relation. Among other results was the establishment of an extensive system of junior county scholarships which enabled a number of children from elementary schools to pass

annually to secondary schools. It was found that these scholars, coming from homes without a cultural background, needed above all some literary training through the mother-tongue. This led to reconsideration of the scope of English both in the secondary and elementary schools and the methods of teaching it. Important suggestions were made in the report of a conference on the teaching of English in London elementary schools (1909). Among the points on which stress was laid were the importance of oral work and the necessity for the ample provision of reading-books of good literary quality. As a result of the conference a circulating scheme was arranged by which 40,000 sets of books passed from one London elementary school to another. Oral work, with all that it involves—enunciation, pronunciation and expression—was dealt with more fully in the report of another London County Council conference on speech-training (1916). The emphasis on English as a *spoken* language is one of the chief notes of progress, to which the study of phonetics has contributed.

In the secondary schools, the growth of higher education for women has been favourable to the teaching of English. In girls' schools the mother-tongue had not to fight for its place against a traditional classical supremacy and advance was easier. For the majority of girls a liberal culture had to be chiefly based on modern, especially English, literature, and women began to specialize as teachers of the subject. But with the growth of "advanced courses" in modern studies, and other post-matriculation work in English, the necessity of specialists and of libraries for the use of themselves and their pupils became evident in both boys' and girls' schools.

Much stimulus to English work, especially in secondary education, has been given since 1907 by the English Association. Many of its pamphlets deal with aspects of English in the secondary school curriculum, and its conferences give opportunities for discussion.

It was partly due to a suggestion from this Association that Mr. Herbert Fisher, when president of the Board of Education, appointed in May, 1919, a departmental committee to report on the teaching of English in England. The committee, of which Sir Henry Newbolt was chairman, issued in 1921 a comprehensive report dealing with the teaching of English in all its stages from the elementary school to the university. It emphasized its position as the only possible basis for the humanistic training of the nation as a whole. The report was a survey and a statement of principles, and not a handbook of methods. But it has already had important practical results. The course in English for training college students has been remodelled; a London university diploma in dramatic art has recognized the part now played in the schools by dramatic work; and the number of scholarships and fellowships in English at the universities, though still inadequate, has increased. Without such support and recognition English cannot maintain its due academic position; and it is to the universities, with which the training colleges are being more closely associated, that the schools must look for a constant supply of fully qualified teachers of English, to consolidate the position that it has taken so long to win.

HISTORY

For many years the neglect of History teaching in British schools contrasted strangely with the practice of almost every other civilized country. In 1868, Matthew Arnold had (in a Training College Report) pleaded for "broad views over the history of our race . . . and its connection which universal history gives."

It was not till 1900 that the elementary code made history an obligatory subject. Every school in the country has now added history to its curriculum. The Board of Education's *Suggestions for Teachers* (1905–27) show how the attitude towards school history has been revolutionized. From being treated almost exclusively as a bare political outline, often read aloud by the class from dull unscholarly "readers" giving odd bits of dry information, it has been extended till it includes all aspects of history: for example—social, economic, civic; local and imperial; the great names and discoveries of science (the steam engine "as a symbol of one of the greatest changes in history"); and, especially since the World War, European and universal (including Ancient and Biblical) history.

Methods have been no less transformed. There is more study of books—of less narrowly-conceived text and other books—and closer contact with literature. The increasing use of "sources," of time-charts, of historical atlases and maps, involving co-ordination with geography; visits to museums and monuments; the use of illustrations (pictures, portraits, cartoons, models, facsimiles of historic documents) and of the rich treasures of the British Museum—all have gone to improve the technique of history teaching in every type of schools.

It was not till the organization of secondary schools by the State that history became established as an essential part of their curriculum. The Education Act of 1902, the Board of Education's Circular 599 (1908), the institution of approved examinations and the organization of advanced courses (1917) for secondary schools, mark an epoch. Concurrently, the movement has been fostered by the foundation of the Historical Association (1905), and especially by the establishment of university history faculties which resulted in a growing stream of trained students, thus making possible "specialist" teaching in secondary and other schools. The university local examinations which had dominated secondary schools unduly stressed the isolated "period" in preference to the "wide-outline" scheme; but recent official changes have caused the general adoption in the school syllabus of a complete survey of British history with the relevant European history treated concurrently. Modern history, especially the 19th century or some other "special topic," now receives more adequate attention and is studied, especially in the Advanced Courses (modern studies), with the corresponding literature.

The publication of Green's *Short History* represents a landmark in the revolution outlined above. And in the realm of examinations, the pioneer work of the Civil Service Commission calls for special mention. "The revelation of that vision of a higher entity to which we all belong" is (writes Sir Stanley Leathes) "the single greatest gift of history, comprehending all gifts of wisdom and beauty and inspiration which we are capable of receiving." Whither examinations lead, schools are prone to follow.

MATHEMATICS

It is beyond doubt that in the present century a revolution in the teaching of school mathematics has taken place. In part it consists in breaking away from the teaching of geometry by means of Euclid's elements and in part that break is typical of the change that has also taken place in the other branches of school mathematics, algebra, trigonometry, Cartesian geometry, mechanics, and arithmetic.

Up to about the year 1900 school mathematics centred around "Euclid" as the subject of geometry was then universally called. The teaching was based on the belief that the subject had a sure foundation in the fundamental assumptions, that the superstructure was raised on the foundations by a process of irrefragable logic, and that the best training consisted in the reproduction of Euclid's reasoning. The impulse towards reform came

from the realization by the teachers that the teaching did not always furnish a training in reasoning to certain of their pupils, who committed the book to memory and reproduced it mechanically and without understanding.

Reformed Methods.—The reform was due to the Mathematical Association. The reformers set about the designing of a course suited to the average child. Text books were written from which the more subtle of Euclid's propositions were omitted and only those propositions retained that had a substantial meaning. To make it possible to carry out the reform it was necessary to secure the sympathy of examining bodies. The Civil Service Commission was the first to support the movement. The old examination paper consisted of propositions, the writing out of which might not indicate understanding, and of problems which certain pupils could not touch. The task of the examining bodies was to find questions on the subject matter that would test understanding and would at the same time be within reach of the average child.

On the old system each branch of mathematics was a separate subject fashioned as far as possible on Euclidian lines with a series of set propositions based upon definitions and axioms. The reform movement led to the disappearance of the lines of demarcation between the branches and their fusion into the single subject of mathematics. At the same time things of little practical value like the theory of numbers were dropped. The time saved by this fusion and pruning was utilized to carry the more important subjects farther and to introduce new subjects. The infinitesimal calculus thus entered the school curriculum and is now sometimes taught from the age of 14. Before the reform numerical work was almost confined to the teaching of arithmetic, being rare even in the supposedly practical subject of trigonometry. It has since played a great part in all varieties of mathematics.

Mechanics.—Mechanics gained greatly by the reform. The pupil now verifies the laws by laboratory experiments. Formerly much energy was expended in deducing the parallelogram of velocities and the parallelogram of forces from fundamental assumptions. The conception of "simultaneous velocities" which is the last remnant of the old system must soon disappear. The subject has been extended to include moments of inertia and simple motions of rigid bodies.

Geometry.—In geometry after the reform the methods of Euclid and Descartes enjoyed equal status and each problem was treated by the most appropriate method. The set propositions of conic sections disappeared. In the time saved geometry of three dimensions was taught, chiefly on the methods of Euclid and Descartes, but also to a small extent on the method of Monge, the graphical method by means of which every point and line of a three-dimensional figure can be represented on a two-dimensional sheet of paper. This method which has great educational value and is in constant use in the engineering world will no doubt be given its proper place in the school; geometry will then be treated by the three co-equal methods, the synthetic method of Euclid, the analytical method of Descartes and the graphical method of Monge.

Relativity.—Mathematical teaching will have to take account of the theory of relativity, and while the chief effect will be on the universities, the schools are concerned in one particular. On the relativity theory it is only in a restricted region that Euclidian conditions hold. The treatment of parallels by the study of their behaviour at infinity therefore becomes invalid. Other treatments that do not trespass beyond the restricted region are now to a small extent in use and must in time displace the Euclidian treatment. (D. B. MA.)

ARITHMETIC

In arithmetic the guiding idea of the reform was contact with reality. Except for mensuration which had to some extent preserved contact with reality, arithmetic before the reform was chiefly mechanical computation, the pupil being told which process he was to use. The reform substituted problems from every day life and left the pupil to decide on the process. The change is well illustrated by one of the early reform questions. The question being "Mr. Gladstone was born in 1809 and died in 1898; how many years did he live?", one candidate replied "I do not know whether this is multiplication or division," while another used multiplication and gave the answer as "3,433,482."

This laudable striving after making arithmetic entirely concrete and practical has led however in some instances to a form of pseudo-realism which though clothed ostensibly in a concrete form, postulates (say) the mowing of an impossible number of acres by a certain number of men in a fixed time, to cite only one instance, taken from a paper set in a recent public examination. Again the attempt to base the early teaching of arithmetic predominantly on logic is being challenged to-day, mainly in America, by psychologists. It is asserted that many children, especially young children, like to perform numerical manipulations without the conscious need to understand their rationale and that rote and even the recitation of the multiplication table are a pleasure to such minds, the reward in such cases coming from the sense of rhythm and of enhanced skill and dexterity, together with the immediate satisfaction of getting the sum right. There is probably a good deal to be said for such types of mind that are content with the "how" and ignore the "why," practical types of mind that instinctively prefer doing to thinking how a thing is done; their motto seems to be *Primo agere deinde philosophari* (first act, then analyse), if we may slightly alter Bergson's favourite phrase. Possibly between these two extreme views, one that builds on conscious logic, the other on the formation of accurate automatisms (sub-conscious logic), the real deciding factor is the "mental age" of the child. With very young children the automatic process should be at its maximum, as in the older ones the rational should be predominant, though neither should be absent at any period. Both elements, mastery of technique and mind-training are indispensable; the problem lies in the particular weight and importance to be attached to each at different stages of the course.

BIBLIOGRAPHY.—The movement was preceded by lectures and articles in papers and reviews by J. Morgan, Henrici, Perry, Benchara Branford, T. P. Nunn and others. Branford's views are published in book form as *A Study of Mathematical Education.* The results of the movement are shown in half a dozen reports by the Mathematical Association on the various stages of mathematical education. *See* also T. P. Nunn, *The Teaching of Algebra* and P. B. Ballard, *The Teaching of Essentials in Arithmetic.* (C. BR.)

SCIENCE

Until recent years science unfortunately was relegated to the specialists, but during the last two decades great strides have been made in the teaching of scientific subjects. That science for all is a national need was one of the outstanding lessons of the World War, and the publication of the report of the Government Committee in 1918, was a great stimulus to discussion and with its many useful suggestions provided a constructive basis for improvement. The method of teaching science having swung from the demonstration lesson to the strictly practical or *Heuristic* (experimental) type has found its level in a balance between practice and theory. There is also a constantly increasing tendency to make the regular school work less and less academic and to relate it more closely with actual life.

Secondary Schools.—In all grant-aided schools it is compulsory to make adequate provision for the teaching of science. The majority of the public schools provide full opportunities for boys wishing to take the subject, but they do not all sufficiently recognize the principle that science should form an important and necessary part of education. The introduction of advanced courses into the larger secondary schools has improved the organization of the subject while leading to the provision of better apparatus and more comprehensive reference libraries. The abolition of examinations of the Junior Local type and the improvements made in the first examinations have done much to encourage a wider conception of the subject. Nature study and elementary measurement are usual in the lower forms of all schools but in the majority of boys' schools the science in the upper classes is confined to chemistry and physics, in very few cases is biology added; in some of the larger girls' schools physics, in addition to both

botany and chemistry, is given to the university examination level, but in the smaller schools, botany alone remains, in others botany or chemistry, only in very few cases is physics carried to any high level. Zoology and hygiene are almost negligible subjects in all types of schools; but some hygiene is taught incidentally in certain girls' schools.

Elementary Schools.—In spite of much progress compared with the past, the teaching of science in these schools is still handicapped. This is due, in parts of the country, to the lack of adequately equipped laboratories in all but the larger boys' schools, partly to the large classes, and to the comparative lack of science specialists. In the girls' schools, a laboratory, if provided, is seldom equipped with water and gas and often has to be used as a classroom. The curriculum generally takes the form of nature study in the lower school which is followed by the teaching of everyday science. The time devoted to the subject varies from one hour to two and a half hours per week. In the girls' schools some of this time is given to hygiene and physiology. In central schools the conditions are better and the science taught varies very much with the district and as a whole is adapted to local environment.

Summary.—The teaching of science has much improved in all departments of education, but there is still (1928) room for further development. More laboratory accommodation and better equipment would solve the main difficulties in many secondary schools. As for the lack of biological teaching in boys' schools it is due to some extent to the scarcity of graduates qualified on the biological side and the demand will probably secure the supply in the future. Headmasters are now quite alive to its value.

For the elementary schools, with certain exceptions, the chief need is for better laboratory equipment. Other desiderata are the reduction of classes, the provision of science specialists on all staffs in the towns, and special classes for teachers in rural districts. With the increased interest in national health the teaching of hygiene on scientific lines should also be a part of the science curriculum in all schools both secondary and elementary.

See *Report* of the Committee on the Position of Natural Science in the Educational System of Great Britain (1918) and *Report* of an Enquiry into the conditions affecting the Teaching of Science in Secondary Schools for Boys in England (1927), both H.M.S. Office.

GEOGRAPHY

While under the capable leadership of Dr. H. R. Mill, the late Sir John Scott Keltie, the late Prof. Herbertson, the Rt. Hon. Sir Halford Mackinder and others, the study of geography in Great Britain has attained to a distinctness of aim, an individuality of method, and a coherence of content which have entitled the subject to be regarded as an important element in the education of future citizens. But it follows that geography has its full educational value only when it is so taught as to represent faithfully in the classroom the spirit and character of the corresponding movement in the wider intellectual world. This means that school geography is not, as it was 30 years ago, the mere learning of geographical data and results, but a training in the geographer's characteristic methods and principles of interpretation, and an assimiliation of his characteristic point of view.

It is now generally agreed that school geography is mainly concerned with the study of the adjustment of the life, the activities and the distribution of man to the conditions of his environment. In studying any particular area the paramount task at all stages of the teaching is to examine the present "adjustment" as carefully and accurately as possible, a difficult task whose importance is even now hardly realised. In the more advanced stages of teaching the interpretation of the present "adjustment" sends the student to other subjects—History, Geology, Climatology, etc.—whose results are taken and used by the teacher for his own special purposes. Nor can the geography of a region be understood unless its relations with other regions, both near and far away, are studied. Most of these geographical distributions and adjustments, as well as internal and external regional relationships, are capable of both graphic and verbal portraiture. The mapping of geographical material in the geographer's characteristic way, and the development of the art of verbal description are matters of great importance to the modern teacher.

Geography has an invaluable contribution to make to the equipment of the educated citizen of to-day, for its study brings to one focus, naturally and without forced correlation, the three elements found constantly recurring in home and world problems: the personality and potentialities of a district or region; the characteristics, needs and outlook of its inhabitants; and the nature, needs, and results of their work. These three elements will be recognized as the "place," "folk," "work" of Professor Patrick Geddes. Good geography teaching is constantly dealing with the relations and interactions of these three, and with their synthesis, and this inevitably develops in its students extremely valuable habits of mind.

Modern geographical teaching has been criticized on the ground that it deals too much with broad generalizations and too little with an accurate knowledge of particular examples. It is said that before the introduction of the new methods pupils did at least know the whereabouts of places on the map and that they amassed facts concerning the limited areas then studied in school. The world is a big place, it contains many countries, while the time devoted to geographical study in schools is short. Nevertheless, it should be the aim of the teacher to give that broad study of the world which modern conditions demand, and side by side with this, so to arrange the syllabus that at each stage some important areas or problems are studied as fully as possible within the limits of the time allowed and the stage of advancement of the pupils. Fortunately the general acceptance of the regional treatment of geography assists both objects. Extensive and intensive studies should proceed side by side.

(L. Br.)

MUSIC

The teaching of music at the beginning of the present century was practically confined to class singing, but with the increasing recognition of the subject as an educational force, a demand for more scientific methods arose. All the newer ones worthy of serious consideration tend in the same direction; the understanding of music. While the method of singing classes has been retained, the work has been carefully graded. Certain apparatus is practically indispensable. (1) Song books containing a large selection of national or folk songs; graded sight singing books; small manuscript books. Copies should be available for every pupil. (2) Sheet music, modern and classical, from any of the now widely known series of school songs. (3) A good pianoforte in a spacious room, preferably on a raised platform. (4) Wall blackboards, with the lines of the stave at least 2 in. apart, and a modulator. A gramophone, or a pianola will be found very useful for certain kinds of teaching. Some schools also make use of the wireless. For quite young children a set of percussion instruments is often provided, and a percussion band is formed, with frequently excellent results.

Practically all teachers agree that the *sol fa* system of pitch names and key relationship, as shown on a modulator, should be retained; but the exact stage for the introduction of the staff notation is still debatable. The more modern method is to begin at once with the staff notation in the lowest class, and to disregard the *sol fa* notation as such, while applying the *sol fa* method to the staff notation. (*See* Musical Notation.) From the elementary training of the ear, and simple musical dictation, to the understanding of a movement of a symphony is now one connected chain of teaching. Two important links in the chain are the study and the writing of short melodies, and the study of simple binary and ternary forms. The term "musical appreciation" is often used in this connection. It means, of course, teaching children to *understand* music, inculcating in them, at least in some small degree, the faculty of discrimination. Aural culture has been well described as "educating future audiences."

The comparatively recent revival of folk song and folk dance has had a remarkable effect on the teaching of music. Folk music

has given teachers a new criterion. Simplicity, directness of expression, rhythmic freedom, unfettered melodic outline, and modal tendency are to be noted in these melodies. Before leaving school, a boy or girl should know a great number of these lovely songs and dance tunes.

The theories of Jacques Dalcroze have found wide acceptance in schools. Put briefly, his method is to teach music through movement and gesture. Much, however, depends upon the quality of the teaching, and a preliminary course of training is necessary. (*See* EURHYTHMICS.)

The old idea that a boy should drop singing when his voice breaks is now discredited by many enlightened teachers. If he is taught to use his newly-acquired "man's voice" with discretion, no harm will ensue. In any case it is not necessary for his general musical education to cease. The formation of a voluntary musical society or club in a school will be found to react favourably on the school music by interesting and inspiring its members.

A golden rule is to conduct as little as possible for simple songs. Many teachers have given up the use of a baton, conducting with the hand only.

The time table should be carefully planned. The time given is often a minimum, especially in the upper forms, owing to the requirements of examinations, though there are hopeful signs that singing will take a more prominent place in these forms than in the past. (*See* also MUSIC, TEACHING OF.) (G. SH.)

ART

When it was first introduced into the schools, whether elementary or secondary, the teaching of art was based on the old academic system, whose ultimate aim was technical attainment. The course started with exercises in the drawing of perpendicular, horizontal or oblique parallel lines, followed by similar graduated exercises in curves, leading up to the development of several *motifs,* with the Greek Anthemion or acanthus as their final objective. Geometry and perspective were then introduced and the knowledge thus acquired was brought to bear on model drawing, which was taught in the same methodical manner.

The formal system held sway for a generation. Then followed a period of experiment and revolt. Many systems, often competing ones, sprang into existence. Ambidexterity, brush work, mass drawing, pastel work—all had their vogue. But certain features have come to stay—imaginative and memory drawing, the careful delineation of natural objects, the practice of design with a specific object in view as against mere pattern making. A point on which there is less agreement is the extent to which the child's imagination should be allowed free rein at the possible expense of acquiring adequate technique. It is the old quarrel between the modernists and traditionalists and possibly the truth lies somewhere between the two. All good teachers however are unanimous in holding that the main idea should be to develop the pupil as far as possible on his own lines, and not as a mere replica of the teacher. In fact the general effect has undoubtedly been to make for greater freedom all round, and for this we have to thank the psychologists, one or two of whose works are quoted in the bibliography. The subject has also considerably gained in prestige in the schools. To-day in elementary and central schools it is taught throughout; and in the latter by a specialist teacher.

In the secondary schools a great step forward was taken when art, in 1924, was made a subject in the general school examination, while art can now be offered as a main subject in the advanced course. (*See* SECONDARY EDUCATION.) Further advance will be possible in the elementary schools by the appointment of a specialist to organize the subject. In the secondary schools the next reform in view is the recognition of art as a second subject in the arts and crafts group for non-linguistic or non-mathematical pupils in the general school examination (*see* EXAMINATIONS), while a growth in the number of advanced courses in art may also be confidently anticipated. Again in many schools of both types greater co-ordination between the other subjects, all forms of handicraft in particular, is also overdue.

Finally it should be pointed out that the schools do not aim at producing a small number of skilful executants—though, with efficient teachers, advanced courses and sufficient scholarships to higher places of art teaching, this should be increasingly possible. The chief objective is the aesthetic and mental development of the pupil through the arts as one of the main channels of culture, which is still too often interpreted in England in purely literary terms. All pupils cannot be expected to create works of art, but practically all may be taught to appreciate them. Hence the teaching of *appreciation,* both by direct and indirect means, forms today an essential feature of art education.

HANDICRAFT

The introduction of the crafts into elementary schools was authorized by the Education Code in 1890. Prior to that the School Board of London, aided by the City guilds, had already provided instruction in a limited number of schools. Since then the number of school workshops has steadily increased and now, in both elementary and secondary schools, the provision of handicraft is compulsory. The training in the crafts is strictly non-vocational, and the value of the cultural content predominates. Several of the school leaving examinations now include both woodwork and metalwork as subjects for presentation.

Types of Work.—The chief crafts for boys are:—Woodwork, metalwork, basketry, printing, bookbinding, leatherwork, the plastic arts (modelling in clay, wood and the softer metals), etc., whilst the most important crafts in girls' schools are:—Needlecraft, weaving (raffia, basketry, textiles), the plastic arts, leatherwork, printing and bookbinding. Some of these crafts require special accommodation and equipment, and very often one workshop serves several elementary schools. The children usually attend one or more sessions per week. Boys' central and secondary schools are practically all provided with workshops.

Woodwork.—Woodwork is the most popular subject for boys. The tool equipment need not be elaborate and, usually, timber is easily obtained and is capable of being worked by boys. The commoner metals also give good scope for training, particularly in conjunction with the woodwork. A few simple machines are necessary (lathe, drill, grinder, etc.), though much useful work may be accomplished with the ordinary hand tools (hammer, chisel, file, hack-saw, etc.). The bench-work is accompanied by working drawings made by the pupil, and good technique is insisted on throughout. After the preliminary exercises have been worked through, a fair amount of liberty is usually given in the choice of articles made. Various interests, belonging to both home and school, are catered for. This is in accordance with the recent tendency towards encouraging originality in the pupil. When the subject was first introduced technique was insisted on far too rigidly. In order to encourage the application of good design in the exercises, every well-equipped workshop has its small reference library of good craft books. There is a growing co-ordination between the teaching of art and of crafts, and the latter is occasionally combined with teaching of applied mathematics in the case of mechanics.

The majority of the other crafts may be taught in the ordinary classroom, especially if strong tables are used instead of the sloping desks. In most modern schools a room is set apart for practical work.

Teachers.—The City guilds of London Institute grant qualifying certificates to teachers in various crafts, and many of the training colleges now give craft instruction. The Shoreditch Training college provides a specialized course for men in both woodwork and metalwork.

DOMESTIC SCIENCE

The teaching of domestic subjects in public elementary schools is nearly as old as the school itself. Stimulated by Government grants, awarded on results, the numbers receiving some sort of instruction in domestic subjects rose from 844 in 1874 to 59,812 in 1882. In 1898 records show that cookery was taught to 181,973 girls, while in 1924–25 the number receiving instruction in domestic subjects was 488,584.

It is easier to obtain pupils than to create teachers, and as late as 1907 Board of Education reports contain adverse criticism of teachers, methods and results. The failure of early attempts to include cookery in the ordinary teachers' training course was a foregone conclusion. The last decade of the nineteenth century, however, saw the establishment of a number of important domestic science training colleges and the enlargement and improvement of others, both in London and the provinces. All those recognized by the Board of Education offer a minimum two year teachers' course which may be supplemented by additional specialization, and only students trained in such courses are eligible to teach domestic subjects in public elementary schools.

In the practice of the higher schools there is no sort of uniformity: most grant-aided secondary schools find room in their time-table for domestic subjects, others do not always do so. Of the 25 schools controlled by the Girls' Public Day School Trust, which between them provide for nearly 10,000 or about 7% of the total of secondary school girls, less than one-third make adequate provision for such teaching. But the tendency is all in the direction of providing it, if circumstances permit, and it is significant that the Headmistresses' Association, in pressing for the reform of the First School examination (*see* EXAMINATIONS), suggests that group IV. (music, art, housecraft or other crafts) should be allowed to rank equally with the languages and mathematics and science groups towards a pass in the examination, urging that if the subjects of group IV. as they now stand, are not held of equal value with those of other groups, this inferiority lies in the syllabus and is not inherent in the subjects.

The most noteworthy attempt to remove the stigma of inferiority from the teaching of housecraft was the foundation in 1908 of the Household and Social Science Department of King's College for Women. There seemed no doubt that the somewhat mechanical methods in vogue and the stress laid on manipulative skill apart from scientific principle, were responsible for the failure to attract girls of brains and ability. The new course, with a curriculum which included, besides physical and biological science, instruction in hygiene and economics, was recognised by the University of London, at first by the award of a diploma to successful candidates, and since 1920 by a B.Sc. degree. A course on similar lines has been recently instituted by the University of Bristol, in co-operation with the Gloucestershire Training College of Domestic Science. Another development which will bring the domestic science colleges into closer touch with the universities is the new scheme by which, from 1930, the Board of Education will discontinue and the universities will take up the conduct of examinations for teachers in training. (H. Re.)

RELIGION

Public interest in the problem of religious education in England centres largely on its position in the primary school. Up to 1870 such instruction was largely provided by the two great school societies, the National Society and the British and Foreign School Society, and these two bodies made further provision for securing such instruction by establishing residential training colleges. From 1870 to 1902 the newly established board or council schools included religious instruction upon an undenominational basis, under the Cowper-Temple clause. The Balfour Act of 1902 financially strengthened the dual system and included in the extended provision for secondary education similar arrangements for undenominational religious instruction. The development of central or modern schools, accelerated by the publication of the Hadow Report on the Adolescent, and the consequent decapitation of many country schools, has intensified the task of the Church authorities in saving their black-listed schools (and with them their denominational religious instruction) from extinction. Great efforts are at present being made both to consolidate and safeguard such schools. As regards the matter of religious instruction in the undenominational schools provided by local education authorities, important advances towards improved and agreed syllabuses have recently been made, of which perhaps the Cambridgeshire syllabus is the best known. Concurrent with these efforts to safeguard denominational religious instruction in non-provided schools and to improve the religious instruction in the provided schools have been attempts to make more general provision in training colleges for instruction in the matter and methods of religious education. The Board of Education does not make such provision in non-denominational training colleges and university training colleges obligatory, but the general atmosphere towards such provision, especially upon a voluntary basis, is very favourable.

Religious instruction in other than primary schools has received increasing attention in recent years. Problems arising out of its place and character in public schools have been the subject of many private conferences, while the work of the late Dr. Sophie Bryant was influential as showing what could be done in large modern high schools for girls. Many movements variously directed towards special problems of religious education have accordingly sprung up. The Student Christian Movement exercises a world-wide influence amongst students of all classes, creeds, and races and is especially active in publications and international conferences. It stands mainly for an undenominational but Christian position. The Church Tutorial Association, founded by Albert Mansbridge, is an effort to provide a high grade of religious education to adults by means of tutorial classes. Its success has been substantial but not spectacular. Such schools as those of the Woodard Corporation, founded with the express purpose of providing secondary and public school education upon a definitely Anglican (High Church) basis have more than held their own during the past half century, and have led to similar foundations by adherents of other types and denominations, *e.g.*, Sherborne School for Girls and the Kingswood school, Bath. The provision for theological education as the necessary complement to general religious instruction has been greatly extended of recent years. Faculties of theology have sprung up in many of the newer universities, and seminaries for prolonged and systematic theological training have been established by such bodies as the Community of the Resurrection (at Mirfield) and the Society of the Sacred Mission (at Kelham). The Sunday schools of the country are now largely run upon reformed lines and vacation schools for Bible study and training in the methods of religious instruction are frequent and successful. The larger problems, however, of confirming the religious education of the nation have led to the establishment by the archbishops of Canterbury and York of a strong committee of enquiry.

In the Dominions, where State provision for religious instruction in the schools normally follows undenominational lines, the denominational supplement largely depends upon the local churches and upon assistance from societies with their headquarters in England. In German schools, the position of denominational religious instruction has been somewhat shaken since the establishment of the republic. In France the opponents of secular civic instruction have pointed to the free Catholic schools as a bulwark for religion and morality alike. In Italy under the present régime religious instruction in the schools has been strengthened, but how far in a really liberal and free direction it is difficult to say. Everywhere, the more technical problems of the treatment of scriptures, of creeds, of competing world religions, are receiving increasing attention.

THE UNITED STATES

Since 1900 the outstanding problem in the curricula of the schools of the United States has been the selection of material. Prior to the opening of this century, the traditional curricula were accepted without serious question. During the colonial period they were dominated by British practices and traditions. Text-books used in the United States were printed in England, and British courses of study were only slightly modified for use in American schools. Even when, following the American Revolution, America began to print its own text-books, their content was not materially changed until the 20th century, and in some fields no important changes have yet occurred.

The principle of selection with which the schools of the United States are experimenting is that of usefulness. But to American thought the concept of usefulness is given a meaning sufficiently broad to include aesthetic, social, moral and intellectual, rather than merely vocational and financial uses. Utility was not always of major importance in curriculum construction. For centuries educators assumed that the organized fields of knowledge—grammar, history, botany, mathematics, and the like—were appropriate for instructional purposes. The practical value of these courses of study was based upon the doctrine of transfer of training, expounded by Locke in the 17th century. In 1902 Thorndike's studies on the transfer of training appeared, causing educators to question the adequacy of the text materials to train students in those abilities which are useful outside of school.

The exploration of the concept of usefulness has taken several directions in the United States. One approach is through activity analysis; another is by way of the long familiar organized fields of knowledge. The investigators interested in discovering the activities, needs, problems or interests of the persons to be educated are divided into two groups, one interested in exploring children's activities, and the other adult activities. The former group, which asserts that the "school *is* life rather than a preparation for life," to use Dewey's phrase, more or less consciously analyses child activities and interests to discover the most important of these; and upon them they base the curriculum. Numerous studies of children's spelling vocabularies, their errors in language, their use of mathematics, and so on, have been made and an educational cult, the so-called "progressive" education (*q.v.*), has arisen. A second group, which assumes that the school is an agency established by the State to teach the young the patterns of behaviour which a good citizen should follow, have analysed the activities, interests and problems of adults, and have based the selection of their curriculum on the results of such analyses, with adaptation of the material to children's interests and activities. Careful studies have been made by this group. Studies of adult vocabularies and errors, of the use of mathematics, geography, history and the like, have been published. The second group has been interested also in the analysis of vocations as a basis for the selection of materials for vocational curricula. Analyses of the activities of pharmacists, secretaries, machinists, and a wide variety of other occupations were made in constructing a curriculum for each.

Those investigators who still approach the curriculum through the organized fields of knowledge, have felt the influence of the concept of usefulness and have made adaptations of their courses accordingly. In the elementary school and junior high school, "general" courses have been organized. For instance, in the junior high schools are found courses in general science which are composed of synthesized materials drawn from zoology, botany, physics and chemistry. In colleges a similar synthesis is seen in orientation courses in which the student is given a general survey of related fields of knowledge. Orientation courses in the social sciences, in aesthetics and in the natural sciences are examples of this tendency. These courses are substituted for detailed introductory courses in the separate fields.

As the concept of usefulness is developed farther, theories of learning, introduced from psychology, have been utilized. With the acceptance of the theory that purposeful learning in solving problems felt to be valuable by pupils is superior to the learning of systematized information, the usefulness of which is not appreciated, the "project" has been evolved. The project curriculum is one in which significant problems, as nearly like life situations as may be, are selected as units of instruction, and such subject matter as is needed is drawn from the organized fields of knowledge in a form appropriate to the completion of the project. This subject matter the pupil is supposed to assimilate as he works through the project. This type of material is having a very wide use, both in the elementary and high schools, and in the vocational schools and colleges. In the college field, programmes which set up conditions for independent study by more mature students have led to the introduction of honour courses adapted from those of British universities and popularized by the Rhodes scholars. The concept of usefulness has also been applied to practice and has given impetus to courses in which the student develops skill in activities in addition to securing information about them. This point of view has been in existence for some time and is found in such forms as that of practice teaching, internship in hospitals, etc. In its newer forms, it is found in co-operative courses such as those developed by the University of Cincinnati and Antioch college, where a student alternates short periods of instruction in school with short periods of experience in business and industry.

The foregoing statement of trends is not intended to imply that the influence of any one will be found in all types of schools. The educational system of the United States is too large in extent and too complex in organization to allow any trend to become universal. Rather these tendencies may more accurately be described as influencing the constructive policies of substantial groups of educators.

RELIGION

The early public schools in America, as well as private and parochial schools, gave full expression to the religious faith of their constituency. Especially in New England, where it was favoured by a sympathetic relation of church and State, the public schools avowed a religious aim and taught religious subjects. *The New England Primer,* for example, for 150 years widely used as a text-book, was largely composed of scriptural and doctrinal material. Catechisms were taught in the public schools and prayer was offered twice a day.

A relative secularization of education has taken place since about 1775. This is in part due to causes which are world-wide, such as the progress of invention and discovery, the expansion of the sciences and arts, and the practical materialism associated with the industrial revolution. It is due also to two principles and two sets of circumstances peculiarly characteristic of the United States. The principles are (1) the religious freedom guaranteed by the national Constitution; (2) the assumption by the States of responsibility for education. The circumstances are: (*a*) the heterogeneity of population which has resulted from immigration; (*b*) the multiplicity of religious denominations, together with the jealous, divisive sectarianism which has in general characterized their defence of their distinctive tenets and practices. The secularization of public education in the United States was not purposed, but incidental—a by-product of the working out of these two principles under the circumstances named. Whenever a minority, or even an individual, has chosen to object, on what are averred to be conscientious grounds, to some religious element in the programme or curriculum of the public schools, that element has forthwith been eliminated, and no other religious element has taken its place.

The movement has been wholly negative. Each religious group has been more concerned to see to it that the public schools should not contain anything out of line with its peculiar beliefs than it has been concerned to preserve in these schools the great principles of morality and religion upon which American citizens generally agree. The result has been to strip the public schools almost completely of religious teaching and religious worship. It is true that in some States and many communities each day's session is yet opened with the reading of a brief passage from the Bible and the recital in unison of the Lord's prayer. With this exception, the programme and curriculum of the schools give practically no place to religion and afford no conscious recognition of the part that religion has played and is playing in the life of humanity. Religious education, it is commonly said, is the business of the home and of the church, not of the school and the community.

In colonial days the churches generally, except in New England, maintained elementary schools, and later took the lead in founding academies and colleges. As the public school system became established throughout the country, most of the churches surrendered the idea of maintaining church-controlled elementary and secondary schools. The outstanding exceptions to this rule are certain German-speaking branches of the Lutheran Church and the Roman Catholic Church. The latter, particularly, dissents in principle from the current policy of public education. Education as a whole is a unitary process, it holds, which must include religion. But the State is not competent to teach religion. The State, may, therefore, levy and collect taxes for the support of schools, may set standards which it requires schools to maintain in certain subjects, and may even conduct schools for those who are without the Catholic faith, if they so desire; but it is the function of the church to carry on through its schools, the education of childhood and youth. Especially since the Third Plenary Council of Baltimore in 1884, this church has laboured strenuously to provide strong schools, organized into diocesan systems, for the education of its young.

In the Colonies religious education was chiefly by means of instruction in doctrinal catechisms. In the 19th century catechetical instruction declined in the Protestant churches; and they came to depend generally, except in the more liturgical communions, upon successive waves of emotional-spiritual revival for the conversion and enlistment even of the children of their own members. Most churches had no definite policy for the religious education of children; they cared little for the increasing secularization of the public schools and failed to realize the larger educational responsibility which was thus being thrown upon them. This failure was due, not so much to neglect, as to the idea that regeneration is quite independent of all natural laws and processes, hence unaffected by nurture and education—an idea which was fostered by the great revival movements. This idea and the practices associated with it were sharply challenged by Horace Bushnell in an arresting book, *Christian Nurture* (1st ed., 1846), in which he maintained, in opposition to the current reliance upon emotional experiences of conversion, that the life of the family in the home is of primary importance in the religious education of children, and that it is possible for a child to grow up as a Christian, and never think of himself as being otherwise.

The Sunday school movement took firm root in the United States early in the 19th century, and expanded rapidly with the organization of the American Sunday School Union in 1824 and the initiation of the International Uniform Sunday School Lesson system in 1872. In spite of ungraded curricula, untrained volunteer teachers and short instruction periods, the Sunday schools rendered indispensable service through the promotion of Bible study and evangelism.

In the 20th century American citizens began to awake to the dangers involved in the omission of religion by otherwise competent public schools and the throwing of the main burden of religious education upon educationally incompetent Sunday schools. The organization of the Religious Education Association in 1903 marks the getting under way of a new interest in the problems of religious education which has grown steadily. In 1920 the Protestant churches united to reorganize the old International Sunday School Association into the International Council of Religious Education. The movement has resulted in the grading of Sunday schools, the devising of better curricula, the training of teachers and the erection of church-school buildings designed and equipped for educational purposes. A new type of church school is being developed—a church school for the teaching of religion, maintained by a local church or a group of neighbouring churches, for children whose education in other respects is provided for in the public schools. These newer church schools are graded in the same way as the public schools; they provide for the religious education of children through activity as well as through instruction; and their schedule includes week-day as well as Sunday hours.

A movement to establish week-day schools of religion is spreading. In many communities, following the example of Gary, Ind., which began this policy in 1914, citizens of all creeds have united in petitioning the public school board to excuse pupils, at the request of their parents, for one or two hours a week of religious instruction. That such a practice is not illegal or contrary to public policy was affirmed by a decision of the Supreme Court of New York in the White Plains case (1927). Its desirability is urged on the ground that it constitutes a recognition by the public schools of the place of religion in human life and of the right of parents to secure the education of their children in the principles of religious faith. Week-day schools of religion are maintained in other communities without time being granted by the public schools. The Jewish congregations have long followed this policy. Throughout the country, there is a notable development of daily vacation schools for the teaching of religion, conducted for terms of two to four weeks. (L. A. WE.)

Soares, *Religious Education* (1928).

SCHOOL AND THE HOME. Direct co-operation between home and school is far less developed in England than in the United States (*see* PARENTAL EDUCATION) or Germany. Nevertheless, English parents and schoolmasters are beginning to think alike, or at least to realize that they are all fighting in the same cause—the welfare of the rising generation. Schoolmasters, thanks to improvements in status and salaries, have largely shaken off the pedagogical dust that was once apt to envelope them. The average parent, on the other hand, is better educated than formerly, and better able to meet the schoolmaster on his own ground and to enter into reasonable discussion of the joint problems of home and school.

Open days, held in connection with civic and education weeks, enable local parents to visit the various schools and institutions which their children attend, and to see for themselves what is actually being done for the pupils. During an education week, the schools of an area usually combine to arrange an exhibition of school work, and to give concerts and demonstrations open to the public. Public meetings are held and addressed by local education officials and officers, as well as by outside educationists or representatives of the Board of Education. All this has an excellent effect in stimulating the interest of parents in schools of the town in which they live. An attractive handbook is usually published at the time setting forth the educational facilities of the area and indicating where further information can be obtained. The London County Council publishes especially valuable guides of various kinds to education and the choice of employment, describing the wealth of educational opportunity provided in London.

A few parents' councils exist in England in connection with public secondary day schools, but these do not compare in any sense with the powerful parent-teacher associations of America. The English parents' council, where it exists, has usually been formed on the initiative of the headmaster or headmistress; its function is to arrange parents' meetings, at which some well-known educationist or the headmaster or headmistress addresses the gathering on a subject of interest to parents. Discussion is invited, but it is rare for animated discussion to arise. An ex-

ception is the Parents' Association (56 Manchester street, London, W.), which is concerned with the interests of parents sending children to public, preparatory and private schools all over the country. The formation of this association was due to parental initiative, and schoolmasters and schoolmistresses, while welcomed as associate members and often invited as speakers, have no voice in its councils. The Parents' National Educational Union (26, Victoria street, London, S.W.) exists mainly for the purpose of furthering the ideals and methods of Miss Charlotte Mason, its late founder. This union, better known as the "P.N.E.U.," publishes *The Parents' Review* and conducts what is known as the "P.U.S." or Parents' Union school, a scheme by which children can work in home schoolrooms and be examined on a common syllabus.

While, no doubt, many of the members of governing bodies of English schools are parents, there has been no general movement towards appointing them as such on these bodies. In 1927 a parent of a boy in the school was elected to the council of a newly created public preparatory school, and the precedent is one that will no doubt be generally followed as parents combine to make their influence felt. Such an appointment, if judiciously made, should greatly help a school, while obviating carping and dissatisfaction. In the few cases where a woman takes an active part on the governing body of a boys' school, her experience is usually of great value in questions concerning diet, health, and the domestic economy and internal finances of the institution. In certain garden cities and satellite towns the elementary schools enjoy the patronage and support of local educational associations which include parents and other citizens. Where such an association exists, there is some likelihood that the children of all classes in the community may attend the public primary schools, as commonly occurs in the United States. A parents' representative is now obligatory (Decree Jan. 24, 1928) on governing bodies of French secondary schools (boys and girls), and such a representative must be chosen from the parents' association, or, in default of such, from the parents themselves.

See Radice, *Home and School* (1926). (S. Rad.)

SCHOOL ARCHITECTURE. Modern school buildings are very different in design from those of the 19th century. It is now recognized that the health and happiness of the children must be the first consideration if they are to take full advantage of the education provided. Consequently, in the latest designs, every effort is made to secure for the children a maximum amount of sunlight and a continuous supply of fresh air, combined with surroundings which are in themselves congenial.

GREAT BRITAIN

The building regulations issued by the Board of Education in 1914, required that the classrooms should not be arranged to open directly from a hall, and in some schools erected shortly after the war these requirements were met in a way that dispensed with an intervening corridor, the rooms not used for classroom purposes being placed next the hall.

On the resumption of building work after the war considerable difficulties in respect of labour and materials were experienced, and as a result one-storey schools of light construction were erected. They were more or less experimental in character but from these has been evolved the latest type which might be termed the open-air type of one-storey elementary school. In these, the classrooms have a southern aspect and thorough ventilation is provided so as to secure the maximum amount of sunlight and fresh air. Experiments have been made with a view to applying the same principles to the planning of buildings of two and three storeys.

The improvement in cross ventilation has made possible important reductions in the heights of rooms. In the Board of Education building regulations (1907) the minimum height of classrooms was laid down as 13 ft. This was reduced in the regulations of 1914 to 12 ft.

Elementary Schools.—The illustration shows the plan of a one-storey elementary school (boys', girls' and infants' departments) on a site sloping to the south. In this plan all the classrooms have a southern aspect. Those on the south side of the open courts are entered from an open verandah; those on the side exposed to the north, from a low corridor over which cross ventilation to the open air is obtained. The halls are central, isolated, and cross-ventilated. The staff room of the girls' department is placed over that of the boys' department. The height of the classrooms is 11 ft.

Secondary Schools.—The requirements of secondary schools are more complex than those of elementary schools; and secondary schools, therefore, present a rather different problem in planning and arrangement. School planning on the lines of the open-air type of elementary school has not yet reached such an advanced stage as regards secondary schools.

It will be seen by comparing the above plans with the plan of an elementary school, that in the secondary school a much larger proportion of the floor area is taken up by rooms for special subjects, *e.g.*, laboratories, art room, gymnasium and manual-training room. In a secondary school dining accommodation is generally provided but not always in a separate dining room. Sometimes the assembly hall and gymnasium are combined, but more usually the gymnasium is kept apart and used for its particular purpose whilst the hall is also used as a dining room. The latest tendency in the design of secondary schools is to approximate to that of elementary schools more particularly as regards the classrooms. (G. T. F.)

THE UNITED STATES

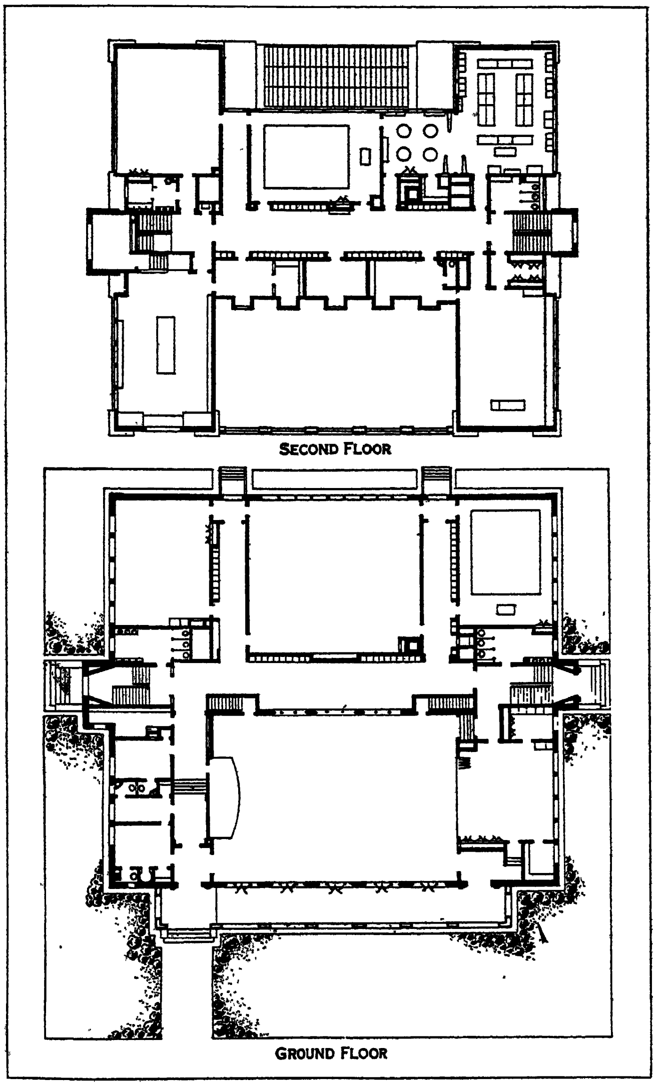
Types of School Buildings.—Originally the school building consisted of a single room or hall. As the schools developed there came into use that treatment of the building having a room in each of the four corners with a hallway through the centre, then came the two storey plan, duplicating the first storey, followed by the three storey building with the third storey containing an assembly hall. These buildings were usually surmounted by a cupola containing the school bell. As the number of pupils increased the need for more space resulted in the addition of more rooms and there followed diversity of arrangement in the general type of plan. These may be classified as the closed and the open types, the closed type being the solid rectangle, the hollow rectangle and the rectangle with interior auditorium and courts, the open type being in the form of one of the following letters: I, T, U, E or H. In determining the type of plan, consideration should be given to the following factors in the order named: (1) orientation; (2) natural light and natural ventilation of the classrooms; (3) expansiveness; (4) flexibility; (5) light corridors; (6) effective supervision; (7) reduction of vertical travel.

The World Fairs held in Chicago in 1893 and in Paris in 1900 (*see* Exhibition Architecture) brought together a brilliant exhibition of school plans which brought immediate results in the planning and designing of school buildings. At the same time the public began to show more liberality in their appropriations and to expect of the architect a higher grade of design and construction. The National Education Association in the United States appointed a committee of its foremost educators and architects to study the planning of school buildings. This committee's report, *Schoolhouse Planning* (1925), provided for a set of standards by which a school-house plan might be measured for right use of floor space, and contained chapters on the process of planning a school building, choice of plan, determining the schedule of rooms, illumination, etc. The National Fire Protection Association acting with the American Engineering Standards committee published a report, *Safety to Life in Schools* (1927), giving rules for planning corridors, stairways, exits and general construction. Previous to 1900 the usual secondary school was easily housed in the old form of school building. There was comparatively little architectural development except in ornamentation. Within the first quarter of the 20th century, however, there developed a movement in school administration brought about by the rising costs of school housing that made a marked impression on the school-house plan.

The idea that each pupil should have one central desk and additional stations elsewhere has been shown to be based on a false

conception of school needs. The superintendent of schools of Gary, Ind., adopting an educational idea that had been in use in Europe, evolved a programme of studies and time periods that made it financially possible for all school committees to give their pupils the benefits of a more enriched programme than was possible under the old plan of administration. The programme plans that every room, hall, shop, gymnasium and recreational centre shall be occupied and in use every school period.

Modern Tendencies.—The modern school-house has unilateral lighting with a glass surface equal to 20% of the floor space and its artificial lighting is laid out in accord with the code of the Illuminating Engineers' Association. Better construction means greater resistance to fire and few schools are now built without fire resisting corridors and stair wells. There are fire alarms and means for extinguishing fire. The building, also, is divided into sections by means of fire doors that automatically



FRANK IRVING COOPER CO., ARCHITECTS
JUNIOR HIGH SCHOOL, LONGMEADOW, MASS.

close when the electric latch holding them open is released by the current sounding the fire alarm. School toilet rooms are located on the various floors instead of being concentrated in the basement, and they have the same type of fixtures as are found in the home. The heating and ventilating plant of educational buildings has been developed; and while there are differences of opinion as to the best type of ventilation, it is agreed that ventilation is necessary and the amount of fresh air to be supplied is prescribed by law in nearly all the States. Physical training is now often required, and this has led to some school buildings being provided with gymnasiums, showers and swimming pools. There is a growing tendency to plan a building so that it may be altered to meet the demands of a changing school programme without undue cost. In general this means providing rooms that may be enlarged or reduced in size without destroying vital parts of the school-house structure. There is a small but insistent demand for rooms equipped so that the laboratory method of teaching may be employed. By this method the pupil may receive instruction based on his own free examination, inquiry and experiment. The modern school building in many communities is equipped for radio reception and also for the talking moving picture. The principal's office may have a microphone transmitter connected to loud speaking telephones in each class room; thus the principal is able to address the entire student body from his desk. In the auditorium the works of the master musicians providing the world's best music may be heard by the pupils by means of auditorium reproducers, actuated by record discs, microphones and amplifiers. Three secondary school buildings near Boston were so equipped in 1927–28,—the first installations of this kind for school buildings in the world. There is also a tendency for auditoriums to be reduced in size and to plan two or more of different sizes in the same building. Rooms for the school nurse, physicians and dentists are often added in administration suites to those for the principal, his clerks and assistants.

Examples.—The development of school architecture in America is nowhere more clearly shown than in New York city, where school buildings may be seen dating from the 17th century to the present year. Nearly all the secondary school buildings were designed while C. B. J. Snyder held the office of architect of the department of education, 1891–1923. His De Witt Clinton high school, 1910, was cited by the United States Bureau of Education as the finest high school building in America.

A small building for 300 pupils, a junior high school in Longmeadow, Mass., designed by Frank Irving Cooper, is of the simplest type. It has a combination assembly hall and gymnasium to accommodate all the pupils of the school; at one end is a stage shut off by folding doors, and when shut off the stage is used by classes in domestic arts. Small rooms are provided for packing away the seats of the assembly hall to make possible its daily use as a gymnasium. Showers and locker rooms are located in the basement. At the rear of the building is a room of large size used as a general shop, and on the second floor are rooms for domestic science. There is a room for the library with an open beam ceiling. There are the usual class-rooms, science rooms, administration suite and rooms for the school nurse and medical attendant. This building is of the U type and additional accommodations may be provided by an extension of the arms of the U.

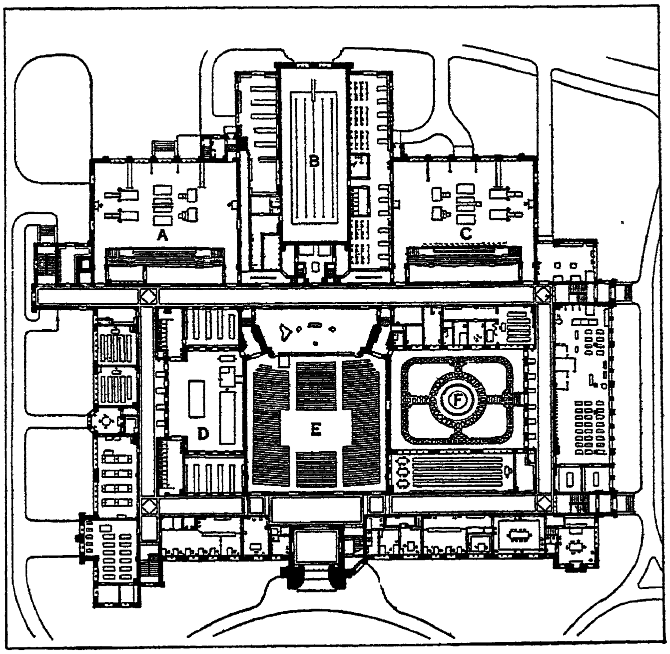
The Bulkeley high school building in Hartford, Conn., also designed by Cooper, shows how the simple type may be used to accommodate a school of nearly 2,000 pupils. This building is of the I plan with the central unit used for academic work. There is a gymnasium at one end and an auditorium at the opposite end of the building. Shops occupy a separate unit at the rear. Each of these units may be used by the school or community without disturbing occupants of the other units.

The Columbia high school, South Orange and Maplewood, N.J., designed by Guilbert and Betelle, is a building with a capacity of 1,600 pupils. There are standard class-rooms supplemented by rooms for special subjects. The auditorium seats 1,300 persons and on the large stage is a pipe organ. Full size gymnasiums are provided for both boys and girls, and between the gymnasiums is a swimming pool with spectators' gallery.

The Central Technical high school, Columbus, O., designed by William B. Ittner, is one of a group of buildings comprising a new civic centre. Its outstanding features are a music-lecture room facing two sunken gardens in the forecourt, the main entrance approach being across its roof, which brings the room into a location where it can be turned over for community uses without entrance to the school building proper; an auditorium, seating 1,500 persons, that combines a gymnasium and stage,—the stage, 20 ft. deep, being separated from the girls' gymnasium by a steel sound-proof curtain, and being adjoined by the boys' gymnasium

on the other side at the rear, thus making it possible to throw the entire health suite together for pageants, large choruses and the social features of the school; and an art group, comprising a room for drawing and a room for commercial art, printing, ceramics and art metal work, grouped on the top storey around an art gallery, the entire group being top or gallery-lighted. The pupil accommodation approximates 1,800.

The Eureka junior high school, Eureka, Calif., designed by John J. Donovan, exemplifies a group development often found



GUILBERT AND BETELLE, ARCHITECTS

COLUMBIA HIGH SCHOOL, SOUTH ORANGE, N.J.

in the Western United States. The 30 ac. of land include a huge gulch which has been converted into a stadium (*q.v.*) encircled by a quarter mile track. Between the shops and the bleachers is the proposed swimming pool, with dressing rooms on either side for boys, girls, men and women. To the south end of the stadium is the proposed open-air theatre stage with dressing rooms, which with the swimming pool pavilions will be built of rustic lumber or of logs.

The first floor plan of the junior high school shows the class-rooms around three sides of an interior court. The north side of the court is formed by the assembly hall, east of which are the boys' and girls' gymnasiums. There are class-rooms, a study hall, library with a stack room, two mechanical drawing rooms, two general science laboratories, administration suite, sewing room, cooking room, typing and book-keeping room, art rooms and an assembly room with a stage that has a seating capacity of 150 persons. The assembly room is used by members of the community as well as students; it has a capacity of 1,200 seats.

Bibliography.—The best sources of information on modern school buildings are the leading architectural magazines of the various countries (*see* bibliography under Architecture) and, in the United States, *The American Educational Digest, The American School Board Journal* and *The Platoon School.* (F. I. C.)

SCHOOLCRAFT, HENRY ROWE (1793–1864), American explorer, ethnologist and author, was born on March 28, 1793, in Albany county, N.Y., and died at Washington, D.C., on Dec. 10, 1864. After studying chemistry and mineralogy in Union college and applying them in a glass factory of which his father was manager, he collected mineralogical specimens in Missouri and Arkansas, and in 1819 published his *View of the Lead Mines of Missouri.* In 1820 he accompanied Gen. Lewis Cass as geologist in his expedition to the Upper Mississippi and Lake Superior copper region, and in 1822 was appointed Indian agent, with headquarters at Michilimackinac. He married Jane D. Johnston, the granddaughter of an Indian chief and the daughter of a wealthy and cultivated Indian trader, who aided him in acquiring information as to the institutions and beliefs of the natives. From 1828 to 1832 he was an active member of the Michigan legislature. In 1832, when on an embassy to some Indians, he ascertained the real source of the Mississippi to be Lake Itasca. Schoolcraft was the author of some stilted verse, of several books on exploration in the Middle West, and of numerous works on the Indians. The most important of these are *Information respecting the Indian Tribes of the United States* (6 vol., 1851–57), a lavishly illustrated compilation issued as the result of a commission by Congress, and *Algic Researches* (2 vols., 1839; 1856 ed., *The Myth of Hiawatha*). Save in the latter volume, Schoolcraft's style is pompous and cumbersome, but he was a pioneer in the work of preserving the aboriginal myths and lyrics. Inspired by his researches, Longfellow decided to weave the red men's "beautiful traditions into a whole," the result being *Hiawatha;* numerous other poets such as J. R. Lowell and T. B. Aldrich based shorter pieces upon his publications.

See his *Personal Memoirs of a Residence of Thirty Years with the Indian Tribes* (1851), which, although poorly digested, gives a fair notion of his work; also an article by F. B. Streeter in the *American Collector* (vol. v., Oct., 1927).

SCHOOL HYGIENE AND PHYSICAL EDUCATION form very important branches of public hygiene in the United States. The school, since practically all the children are collected there, furnishes the great opportunity for caring for the health of all the people. During recent years the importance of this has been recognized, and a great advance both in physical education and in the application of hygiene in the schools has been made. Although they are more or less interrelated, the two subjects may be best treated separately.

School Hygiene.—School hygiene may be divided into four main branches: (1) Sanitation of school-houses and school grounds. (2) The hygiene of the school child, including prevention of contagious and other diseases, health examinations both physical and mental, the prevention and treatment of defects and positive training for the development of habits of health. (3) The hygiene of school teachers. (4) The hygiene of school instruction together with mental hygiene.

The School-house.—This branch of school hygiene is concerned first of all with the best conditions of a workshop for growing children occupied in brain work. Architectural and artistic considerations, although usually considered important, are secondary. First of all should be considered the health of the workers. For example, the unit in a school-house is the schoolroom, and the size of the room should be determined by consideration of the average limits of normal sight and hearing, etc. Many scientific studies of the best forms of construction, and of methods of heating, ventilation, lighting, have been made; and from these and the experience in building millions of school-houses certain definite norms for construction have been established. Although many poor school-houses are still scattered throughout the country in defiance of the rules of hygiene, the best are models of sanitary excellence.

Hygiene of the School Child.—Child hygiene is based upon the character of the child's body and the laws of growth. It seeks to determine the needs and to avoid the dangers of each stage of development. Among its important contributions have been many scientific studies of development, the diseases and abnormalities of school children, the defects of the sense organs, the incidence of disease by years, seasons, months of the school year, the relation of defects to school progress and studies also in detecting and controlling contagious diseases. By the introduction of health inspection into the public schools, not only has the importance of school hygiene been emphasized, but valuable material for the study of child health has been collected.

Hygiene of Teachers.—A new branch of school hygiene relates to the health of teachers. The few studies made emphasize the great importance of the health of the great army of teachers. It appears that the members of the teaching profession are prone to respiratory diseases and to nervous disorders. Thus it is seen to be a matter of importance to make conditions healthful for the work and the life of the teachers as well as of the pupils.

Hygiene of Instruction.—This emphasizes the hygienic im-

portance of the mental habits formed by education, the secondary effects of instruction; and it studies every educational principle and method, the relations of teacher and pupil, the problems of the period of study, from the point of view of hygiene.

The importance of this newer field of school hygiene is seen when one considers the fact that an important means of cure for nervous and mental disorder is re-education, the development of healthy habits of mental activity,—wholesome interests, habits of attention, self-control and orderly association,—in fact, the very habits that are essential for hygienic school work. More and more scientific investigation and observation are showing the hygienic importance of mental hygiene both for pupil and teacher.

School Legislation.—The development of school hygiene is shown by the growth of medical inspection as well as by the training of teachers, the legislation in regard to the health of children and the sanitation of school buildings. While none of the laws in the different States are adequate, the legislation indicates fairly well the present interest and aims. According to J. F. Rogers of the Bureau of Education, 42 States make some provision for medical inspection. In 16 States it is mandatory; 19 command or imply a complete health examination of the school children; half the States have legislation in regard to ventilation of school buildings. About 60% of the cities require annual health examinations of the children. In recent years, with increased attention to physical defects as well as contagious disease, the health inspection has been placed largely under the direction and control of the educational authorities.

Physical Education.—As concerns the school this subject may be divided as follows: (1) General physical exercise including play and training in health habits; (2) systematic physical training, gymnastics (*q.v.*), callisthenics, and the like; (3) athletics (*q.v.*); (4) the higher aims of physical education.

Special treatment of gymnastics, athletics and mental hygiene is given under separate articles. Only general aspects of the subject are discussed here.

The importance of physical education in relation to health has been emphasized in recent years in a twofold way: first, because of its significance for the normal development of children and the maintenance of general physical health; second, because of its significance for mental health. The minimum amount of physical exercise for the maintenance and development of physical health has been suggested by Hetherington as follows: Four hours of muscular activity at the age of 5 years, five hours from the age of 7 to 9, six hours from 9 to 11, five hours from 11 to 13, four hours from 13 to 16, three hours from 16 to 18, and two hours daily from 18 to 20.

The slogan of physical education from the days of the Greeks until the present has been *mens sana in corpore sano,* the sound mind in the sound body, with the implication that the sound body is a condition of mental sanity. In modern times, under the influence of the great teachers of physical training in Europe, Guts, Muths, Jahn and others in Germany, Ling and the founders of Swedish gymnastics, the training has naturally centred much more upon physical education. While the mental factor in this twofold aim has often been neglected, in recent times the emphasis has been placed largely on the mental aspects of physical training. In a report of a special committee to the Society of Directors of Physical Education in Colleges made in 1921 the committee emphasized right mental attitudes, self-sacrifice, loyalty and co-operation, and mentioned some of the more generic of these mental attitudes as their first group of aims. Thus to-day there is growing the theory that physical education affords opportunity for important training in mental hygiene as well as for physical health. While we do not go as far as Plato and say that God gave men music and gymnastics for mental culture alone, we do now emphasize the development of healthy mental attitudes and interests as the culminating value of such training.

With the development of physical education in relation to somatic and mental health, it has become a subject for scientific research as well as a practical art, as indicated by recent literature. In the practice of hygiene the best schools to-day supplement instruction by actual training in health habits; and in the colleges the highest ideal is the acquisition of health intelligence as demonstrated by health habits. (*See* also PHYSICAL CULTURE, and for English legislation on the subject *see* EDUCATION.)

SCHOOL LIBRARIES. The school library is a comparatively late development in British Elementary Education. (For the school library in the U.S., *see* LIBRARIES.) Under the old system of payment by results there was little opportunity of straying from the narrow path represented by the "three Rs." But teachers have gradually learnt that with teaching to read, the appetite for reading must come with the eating; the mere teaching of the principles of mastication is of little good. This appetite has undoubtedly been developed within the classroom itself by the system of circulating libraries of reading books, giving a far wider range and choice of interests than when each school had a limited set of readers of its own. But care must be taken to create first an appetite and then taste, though the more ambitious teachers have often begun with the latter. To-day a properly equipped school library contains books for enjoyment and books for information and the cultivation of taste. Books for enjoyment especially, should be attractively bound and if possible illustrated. Children's books should look as tempting as their games and toys, and indeed many school books are attractively got-up to-day, the line of demarcation between the ordinary book and the school book being often very thin. Children should be taught to take reasonable care of books, but they must not be made afraid of them. A set of well-thumbed books is a finer testimonial to a school than a set of immaculate volumes. To tempt the children on to more serious books is part of the teacher's task. Once they have caught the reading habit they may be diplomatically led on to something a little better. The longer works of Dickens and other standard authors may be tackled, provided the teacher knows how to put forward what is best, and how to pass over what is likely to be tedious or unintelligible. Valuable books of voyages, travel, biography should also be brought into their ken. Books for information will include books too difficult to read as a whole, but not too difficult to be used for reference or simpler research. Boys of 13 cannot be expected to read a whole history of English literature, but they ought to be able to consult one. Again, when reading a play of Shakespeare they should have at hand a life of Shakespeare, and a glossary of Shakespeare and other similar books. Among the books of reference Whitaker's Almanac should have an honoured place, especially in those schools where the daily paper is used to stimulate curiosity (by extracts on current events being placed on the notice-board).

Both for pleasure and for profit, a close touch should be established with the local free library wherever one exists. Many free libraries have a juvenile section including sometimes a junior reading room, and work in full co-operation with the elementary school. Private reading makes a full child, and should be one of the best antidotes to the elementary pupils' faults of thinness and discontinuity in reading. The large sale of such series as the Everyman Library, the Home University Library, etc., is clear evidence of the great advance in the standard of popular reading since the beginning of the century. The reference library for teachers must not be forgotten. It ought to be not merely for reference but for more extensive reading. The more advanced local authorities not only provide circulating libraries of books for children, often with the aid of the Carnegie Trust, but have also central libraries where teachers can borrow or consult books connected with any side of learning and culture.

A similar revolution has taken place in the English secondary schools. Books for individual reading are available in class

libraries or in the general section of the library. The most advanced schools draw up lists of story books, often in modern languages, suitable to the age and the class. Some teachers go still further and keep a register under each pupil's name of the books read, which enables them to see that each pupil takes out at least one book per term. Others devote part of the English lesson to description or discussion by the individual pupils of the books read. In spite of the bad name the holiday task has acquired in some instances, a good deal of voluntary reading is done in the holidays. An excellent system is to have a list of books for the pupils to buy and read in the holidays throughout their school life. In this way practically every child on leaving the school has voluntarily purchased and read a nucleus library of some 20–30 books.

Reference libraries have developed in the same fashion, being open alike to the teachers and the children, especially in cases where the Dalton plan has been adopted. Advanced courses have given them a further impetus, as a good reference library in all subjects is indispensable to the advanced student. Local authorities now often make yearly grants for libraries to their elementary and secondary schools. But in spite of much that has been done there still remains a great deal to do in the way of raising all schools to the level of the best and in making the reference library sufficiently comprehensive to meet the requirements of the curriculum and the needs of the teachers.

Similar developments have taken place in the Evening Institutes and Training Colleges and the introduction in the universities of Seminar Libraries in different subjects also marks a great advance. Mention should also be made here of the Central Library for students as well as that in connection with the Workers Education movement, while the Board of Education Library with its 60,000 books and pamphlets is of special interest to teachers and students of education. (G. SN.; C. BR.)

SCHOOL MEALS. The feeding of needy children of school age was first started in France by the institution of *cantines scolaires*. Pioneer work of a similar kind was established at Manchester, Bradford, London and other large towns in the later years of the 19th century. Meals thus provided were usually breakfasts.

The report of the Physical Deterioration Committee published in 1904, and that of the royal commission on physical training in Scotland, published in 1903, led to the appointment by Lord Londonderry of an inter-departmental committee which, in 1905, reported that feeding schemes were in operation in about one-third of the non-county boroughs and urban districts, but that little was being done in the county areas. By the Education (Provision of Meals) Act, 1906, local education authorities were empowered to spend money out of the rates and to recover from parents the whole or part of the cost of the meals supplied, except where the parent was unable to pay. These provisions were consolidated in the Education Act, 1921.

As the chief medical officer of the Board of Education wrote in his annual report (1927), "The problem is not the relief of poverty, but the prevention or amelioration of undernourishment." In that year 389,828 individual children were fed by 173 education authorities in England and Wales; the number of children fed was twice as many as in 1913, while the total number of meals provided was five times as many.

In the United States, school lunches were primarily intended for children suffering from malnutrition, but of recent years, educational authorities in the larger cities have realized that the provision of proper food during the noon intermission for all pupils is now a part of the general educational movement.

SCHOOLS, ANCIENT. This article deals with the history of Greek and Roman schools, from which modern schools are derived. For modern schools *see* SCHOOL AND CURRICULUM and for a general historical sketch *see* EDUCATION.

GREEK SCHOOLS

First Phase.—The term and the institution date, not from the great or what may be called the Hellenic age of Greece, but from the later Macedonian or Hellenistic period. The account given by K. I. Freeman in his *Schools of Hellas* (1907) may be summed up in the statement, "There were no schools in Hellas." That is, there were no schools in the modern sense, where, during boyhood and youth, boys spent their whole time in a continuous course of instruction. There were professional teachers of three kinds: (1) the *grammatistes*, who taught reading, with writing and perhaps arithmetic, in the *grammateion;* (2) the *citharistes*, who taught music, *i.e.*, playing and singing to the cithara; (3) the *paedotribes*, who taught gymnastic, wrestling, boxing, running, jumping, throwing the javelin, etc., in the *palaistra.* To these teachers the boys were taken by slaves, called boy-leaders (παιδαγωγοί, whence our pedagogues), as single pupils, and were not taught in classes.

Roughly, the age for the grammar-school and song-school was 7 to 14, for the gymnastic school 12 to 18. A certain amount of literature was imparted, and especially in the song-school, Homer and other early poets, the very Bibles of Hellas, were learnt by heart. In later days, under the Sophists, and Socrates, "the greatest of the Sophists," 450–400 B.C., something approaching secondary education was developed. But it was wholly unorganized. The itinerant orators or rhetoricians taught oratory, and the learning that was considered necessary to the political orator, a smattering of Greek history, constitutional law and elementary logic. The philosophers, such as Protagoras, discoursed vaguely on natural science, "things in the heavens above and the earth beneath," and divinity, "whether there are gods or not," mathematics and ethics, or any subject which attracted them, while the lawyers, in the same unsystematic way, taught what law was necessary in a State where the Constitution was at the mercy of chance majorities in a sovereign assembly of 30,000 people, and trials at law were settled by 600 jurymen-judges.

Second Phase.—In the next generation, the orators and the philosophers, by settling down in fixed places, began to establish something more like schools. Plato, though like his master Socrates he taught without asking fees, was the first to give a regular educational course extending over three or four years, and in a fixed place, the Academy. The gymnasium was originally a parade or practice ground for the militia or conscript army of the State, which derived its name from the exercises being in that climate performed naked (γυμνός). At the age of 15 or 16 the boys left the palaestra, or private gymnasium, for this public training school, maintained at the public expense, preparatory to their admission as youths (ἔφηβοι), to take the oath of citizenship and undergo two years' compulsory training in regiments on the frontier. After those two years were over, they still required continuous exercise to keep themselves in training; consequently men of all ages, from 16 to 60, were to be found in the gymnasium. Though the gymnasium was free, the teachers and trainers in gymnastics were paid, and as the poorer citizens had to earn their own living, the Athenian gymnasium, like the modern university, was for educational purposes chiefly frequented by the well-to-do. So the Academy became a fashionable lounge, and here developed the walking and talking clubs, which became the Platonic or Academic Schools. Logic and ethics, built on a foundation of geometry and mathematics, seem to have been the staple subjects. An inner circle met, and dined together in Plato's private house and garden, close to the Academy. Plato devised the house and garden to his successor Speusippus, who passed them on to Xenocrates. They thus became the first endowment of the first endowed college, which grew very rich and lasted till the disestablishment and disendowment of the old learning by Justinian in A.D. 529. Aristotle, a pupil of Plato for 20 years, set up a school of his own in the Lyceum, another public gymnasium, where he lectured twice a day, in the morning esoterically to the inner circle of regular attendants, in the afternoon to the public. From these two institutions three nations of Europe have derived three different terms for a school, the Germans their gymnasium, the French their lycée, and the Scotch their academy. Yet none of the originals was a school in any real sense of the word. In the days of their founders they were like discussion forums; at the most, courses of lectures. In later years, the gilded youth who flocked to Athens from the whole Graeco-Roman world were en-

rolled among the ephebi, and the so-called "university of Athens" was evolved.

Third Phase.—It is to the Alexandrines, either to Antiodorus or to Eratosthenes, *c.* 250 (J. E. Sandys, *Hist. of Classical Scholarship,* 7), that grammar, as a term and a science, which included literary criticism and scholarship, and the grammar school are due. The earliest extant treatise on grammar is by Dionysius of Thrace (born *c.* 146), a pupil of the Homeric critic, Aristarchus. It defines grammar as "the practical knowledge of the usage of writers of poetry and prose" and includes exegesis or explanation of the author in the widest sense as well as mere verbal or syntactical grammar. It was from the term thus understood that the grammar school (*scola grammaticalis*), the term which described the typical secondary school from that day to 1869, derived its denotation and its connotation. Throughout the 13 centuries which intervened between Dionysius Thrax and Dr. Kennedy, Dionysius's grammar was the standard work and the foundation, directly or indirectly, of all other grammars, while the grammar school has always meant, and, in the hands of the better class of teachers, has always been, not a gerund-grinding machine, but a place for the training and exercise of the mind by the study of literature. The word "school," as well as the word "grammar," seems to be due to Alexandria. The first known use of it in that sense seems to be in Dionysius Halicarnassus' Letter to Ammaeus, *c.* 30 B.C. But as Plautus (*c.* 210) uses the corresponding Latin term, *ludus literarius,* some two centuries earlier, we may safely infer that he used it as a translation of grammar school.

ROMAN SCHOOLS

First Stage.—At Rome schools began with intercourse with Greeks. According to Suetonius, the emperor Hadrian's secretary, who wrote *The School Masters* (*De grammaticis*) about A.D. 140, literary teaching and the science of grammar began with Livius Andronicus, a Greek from Magna Graecia in the south of Italy, who, being brought to Rome as a slave in 272 B.C., became a freedman, translated the *Odyssey* into Latin, and taught both Greek and Latin. Ennius, the first Latin poet, was also half-Greek, and came to Rome in 209 B.C., where he also taught both languages. According to Plutarch (*Quaest. Rom.* 59) the first grammar school (*grammatodidaskaleion*) was opened by Spurius Carvilius, a freedman of Carvilius, about 230 B.C. According to Suetonius, Crates, who about 169 B.C. came to Rome as ambassador from Attalus, king of Pergamum, a great centre of learning, and was kept there by a broken leg, occupied himself in giving lectures. His example was soon followed by Romans. Schools of grammar, in which, even as late as Cicero's time, the Laws of the Twelve Tables were the chief text-book and were learnt by heart, were kept by Greeks or freedmen. These seem to have been of the nature of elementary schools. But at Rome, as at Athens, the working-classes were for the most part slaves; and elementary schools were like English preparatory schools rather than public elementary schools. Schools of rhetoric, which were more like secondary schools, were also opened after the model of that of Isocrates at Athens. In 92 B.C. schools of Latin rhetoric were put down as an innovation. Yet among the treatises written by Cato, the praiser of the past at the expense of the present, was one on public speaking, the chief rule in which was "take care of the sense, and the sounds will take care of themselves." Neither the gymnasium or palaestra, nor the music school, flourished at Rome. As at Athens, so at Rome the boys were sent to school in charge of a slave, a *pedagogus, comes* or *custos.* But it would seem that at Rome the pedagogus, generally a Greek slave, often himself gave elementary instruction. In Varro's much-debated phrase, "Educat nutrix, instituit pedagogus, docet magister," "the nurse brings up, the pedagogue instils the elements, the master teaches." *Magister*, which in English became "maister" and then "master," remained the term for the teacher of the public school from that day to this, though attempts were made at the time of the Reformation to introduce the Greek word *didascalus* in its place.

The Roman school was very much like the modern school. All the methods of torture which have made the service of the Muses for most boys a veritable slavery were in full vogue. Instruction was now in a foreign language, and grammar became prominent. Early rising, loud speaking and hard flogging were in the ascendant. The staple of instruction in the Roman schools was the works of the poets, Greek and Latin, Homer and Virgil, Hesiod and Aesop, Menander and Terence. Horace says (*Ep.* i. 19. 40) "that he was not thought worthy of going the round of the schoolmasters' desks"; but it was a fate not long delayed, and the writings of the poets of the silver age, Lucan and Statius, became school-books in their own lifetimes.

Our knowledge of the Roman curricula is mainly due to Quintilian's *Institutio oratoria, c.* A.D. 91. Fabius Quintilianus, born on the banks of the Ebro, was not only the son of a man who kept a rhetoric school, but himself kept one, and is said by St. Jerome to have been the first who kept a public school, in the sense that he was the first who received a stipend from the emperor. In endeavouring to create the perfect orator, Quintilian discusses the whole of education from the cradle upwards.

Second Stage.—The first definitely endowed school we hear of is one founded by Pliny the younger, a pupil of Quintilian, at his native place Como. Later historians say that the emperor Antoninus Pius (138–161) assigned offices and salaries (*honores et salaria*) for rhetoricians throughout the provinces; and that Alexander Severus did the same, and also established exhibitions for poor boys, with the limitation, curiously repeated a thousand years later in the statutes of All Souls College and of Eton, *modo ingenuos, i.e.,* provided only that they should be free-born.

There were complaints that the masters were ill-paid. Quintilian made a fortune by his school, but Juvenal calls him in this respect a white crow.

Later Schools.—Grammar and rhetoric schools spread throughout the Roman world and continued substantially unchanged in method and subject to the days of Gregory the Great and Augustine the apostle of the English. The *Confessions* of St. Augustine of Hippo, a schoolmaster at Carthage, Rome and Milan, before his baptism in the year 387, and the poems of his contemporary Ausonius, educated in the grammar school at Toulouse, and himself a schoolmaster at Bordeaux before becoming prefect of Illyria and of Gaul, show that the schools were much the same in the 4th century as in the first. Ausonius celebrated in verse all the Bordeaux schoolmasters, some coming from schools at Athens, Constantinople, Syracuse and Corinth, one the son of a Druid at Bayeux, others schoolmasters from Poitou, Narbonne, Toulouse, who went to Lerida and other places in Spain. Ausonius had for his pupil the emperor Gratian, who in 376 established a legal tariff for schoolmasters' salaries. "In every town which is called a metropolis, a noble professor shall be elected." The rhetoric master (rhetor) was to have at least 24 annonae (an annona being a year's wages of a working man); while the grammar masters were to receive half that. But at Trier, then the capital of the Western empire, the rhetor was to have 30, the Latin grammarian 20, and the Greek grammarian, if one could be found, 12 annonae (*Cod. Theod.* xiii. 3. 11). The same century saw Priscian, a schoolmaster at Constantinople, compose the Latin grammar, which, itself for the most part a mere translation from Greek, reigned without a rival till the Reformation, and is represented by over 1,000 mss. Venantius Fortunatus, educated in the grammar school at Treviso, wrote in 570 a life of St. Martin of Tours in three books of hexameter verse, and lives of saints and bishops. His era was one of transition, and marks the passing of the schools from secular to ecclesiastical control. His contemporary Pope Gregory in a letter to Desiderius, "bishop of Gaul," at Vienne commends the monks whom Gregory was sending with Laurence the priest and Mellitus the abbot to Augustine of Canterbury, thus bringing the grammar-school-teaching bishop into direct connection with the conversion of the English, and the foundation of the first English school.

SCHOOLS, EVENING, schools open in the evening to enable those working during the day to continue their education. Evening schools in Great Britain are discussed under COMMERCIAL EDUCATION, CONTINUATION SCHOOLS and TECHNICAL EDUCATION. The following article describes the work in the United States.

Evening schools in the United States for apprentices and others were opened in New York (1833) and Louisville, Ky., (1834). Ohio (1839) enacted legislation requiring towns to provide evening schools for males over 12 years of age. Massachusetts (1847) permitted towns to appropriate money for instructing adults in reading, writing, English grammar, arithmetic and geography. By 1862 Cincinnati, San Francisco, St. Louis, Chicago, New Orleans and other cities to the number of at least 15 had conducted free public evening schools. Thirty-two cities reported such schools in 1881, and the report of the U.S. bureau of education for 1887–88 showed a total enrollment in cities of 8,000 or more of 135,654. The enrollment for 1925–26 was 937,-736 pupils, of whom slightly less than half were girls.

Classes are maintained in Americanization work, elementary, high school and vocational subjects. The objectives of Americanization work are to teach immigrants to speak, read and write English; to aid them to get an understanding of American institutions; and to prepare them to take out citizenship papers. Many employers co-operate helpfully in this work, and sometimes pay part or all of the expenses of these classes. Elementary classes are for those who wish to obtain further instruction in subjects usually covered in day grade schools. High school classes enroll pupils who wish to pursue work of high school grade in English, history, mathematics, science and classical or modern languages, and also offer courses in such fields as choral singing, dancing, art work and business law. Vocational courses range from work which appeals to an avocational interest in fancy work or manual arts to specific vocational training for office workers, housekeepers and apprentices and journeymen in industrial trades. A typical relative demand is shown in a registration of 200,000 different persons in one year in New York State schools. About $\frac{1}{5}$ were enrolled in Americanization classes, $\frac{1}{4}$ in academic high school subjects, $\frac{1}{5}$ in commercial subjects, $\frac{1}{10}$ in home economics, $\frac{1}{5}$ in industrial, and $\frac{1}{25}$ in elementary subjects.

Pupils usually attend evening school two hours per night for two or three evenings per week, from Oct. 1 to April 1. By increasing the time allotment, Cincinnati, Chicago, Boston, Philadelphia and other cities offer an evening school diploma equivalent to that of the day high school. Rural evening schools have developed an enrollment of more than 15,000. This work is essentially for adult men, and is strictly vocational. The growth of evening schools, more than seven-fold in 50 years, has been phenomenal.

The evening school in the United States, excepting Americanization classes, is chiefly for young working people. The pupils average about 19 years in age and are about equally divided as to sex. (O. D. E.)

SCHOOLS OF ART. As institutions, art schools are comparatively recent. The first signs of organization were perhaps in the Middle Ages when the arts and trades were controlled by guilds. Courses of instruction, promotions, competitions, and general advisory councils were in existence at that time in the more important art centers of England, France, Germany, and, especially, Italy. However, such organizations did not take the place of personal instruction by the masters of the arts, fine and applied. It was to the great artists that pupils looked for supervision, and the term "school" as applied to these masters (such as the school of Michelangelo) has no connection with organized institutions. The 19th and early 20th centuries have seen the birth and development of innumerable art schools, especially in countries where the government has made appropriations for such educational work, but this advancement has not meant the obliteration of personal instruction under pre-eminent artists and it is not uncommon to find students who have never attended an art school. This "personal supervision" system of study has its weaknesses, chief among which is the tendency toward imitation. The artist, in imparting the secrets of his craft, as well as certain generally established laws and traditions, stands pre-eminent, and it is often difficult for his pupils so to forget the tricks and mannerisms of their master as to become individualists themselves.

The modern school of art had its inception perhaps in the Royal Academy of Fine Arts, which was founded in Paris in 1648 and has been running ever since. Like this institution, most schools have their departments of painting, sculpture, architecture, engraving, etc., with the allied arts, in which such divisions as the history of art, theory and practice of design, perspective, etc., are taught in regular classes. Free-hand drawing, involving the co-ordination of hand and eye, is generally used as the foundation upon which most of the training is based. While considerable study is required in history, theory, and in the necessary rules for good design, the emphasis in most modern schools of art is placed upon the actual studio work. With the development of museums where design may be studied from the collections of art work more and more importance is given to observation classes. In many of the municipal museums, especially in the United States, an art school is conducted in connection with the museum (*see* MUSEUMS). For pupils interested in the industrial arts most schools have branches for detailed technical instruction in that field, such as pottery, basketry, carpet weaving, batik work, etc. However, this can be successfully taught only after the pupil has a working knowledge of the fundamentals of drawing and design. (*See* DRAWING.)

Public exhibitions, local and international, have perhaps been the greatest stimulus in the development of art schools in Europe and the United States. About the middle of the 19th century considerable competition in the industrial arts was started among the European countries, which meant decided progress in the manufacture and keener valuations in the design of the products of industry. This idea of competition, which later spread to the United States, has made itself manifest also in local exhibitions in the larger cities.

Of the many important schools of art only a few can be mentioned in the following list. (*See also* SOCIETIES OF ART; DESIGN; PAINTING; SCULPTURE; ARCHITECTURE; ART TEACHING.)

THE UNITED STATES

Special schools of art, many of which bear no relation to the public schools, have a powerful influence on art education in the United States. (*See* ART TEACHING.) While the state universities, larger high schools, and even the lower grades, often have an art department, where drawing and elementary design are taught, they do not provide courses for pupils specializing in one or more of the arts, but rather for those who take a regular course and are sufficiently interested in art to select it as one of many studies. Art schools are, therefore, established and controlled largely by art societies, boards of trustees, and private patronage, a very small number depending upon governmental aid. A few of the large cities maintain art schools, some connection with the museums, and charge only a small fee for admission.

The Departments of Fine Arts in the larger universities of the United States serve as important factors in maintaining the balance necessary for institutions that seek to give an insight to all the arts and sciences. Although most of these departments are closely allied with the College of Liberal Arts and Science, giving pupils who work toward a bachelor's degree the opportunity of choosing one or more of the arts as a "major" or "minor" study, there is a growing tendency to organize all the fine arts into a School of Fine Arts, which can then be divided into its various departments. The University of Pennsylvania is a good example, although it tends to specialize in architecture. In 1920 all of the various divisions of the university providing instruction in the fine arts were grouped together under the School of Fine Arts, viz: Department of Architecture, Department of Landscape Architecture, Department of Fine Arts, and Department of Music. In 1928 there were 31 instructors and 444 students in the school.

Of the other larger universities that have outstanding courses in the various arts, the following should be mentioned: (1) Yale University, School of Fine Arts, having four-year courses in architecture, drawing and painting, sculpture, and drama. The enrollment in 1927 was 705. (2) University of Michigan, College of Architecture, offering three programs, each requiring a minimum of four years. Two of these courses are in architecture, and one is a four-year course in decorative design which empha-

sizes interior decoration, with instruction in drawing, painting, and modeling as supplementary. (3) Carnegie Institute of Technology, College of Fine arts. The most important activity of this department, and the one which distinguishes it from others in the country, is the annual International Exhibition of Paintings. This exhibition has been held each year since 1896 with the exception of the years during the World War. The school intends to specialize in contemporary painting. Practically all of the paintings in the permanent collection date from 1896 or thereabout. (4) University of Illinois, Department of Architecture and Department of Art and Design. (5) University of Iowa, Department of Graphic and Plastic Arts. (6) University of Missouri, School of Fine Arts. (7) University of Nebraska, School of Fine Arts. (8) Columbia University, Department of Fine Arts (Teachers College). (9) New York University, Department of Fine Arts. (10) Syracuse University, College of Fine Arts. (11) Ohio State University, Department of Fine Arts. (12) University of Wisconsin, Department of Industrial Education and Applied Arts.

Of the art schools that are independent of State or municipal control, the better known ones are in the larger cities. In New York, the following list comprises the more important ones: (1) Art Students League of New York, which had an enrollment in 1927 of 2,850 pupils, 28 instructors, and a curriculum that included painting, drawing, illustration, sculpture, etching, lithography, composition, wood-block, sculptural wood-carving, stone cutting, and mural painting. As in most of the larger art schools, evening classes are offered for those who cannot attend during the day. (2) Beaux-Arts Institute of Design, with an enrollment in 1927 of about 2,000 students, and a course of instruction that covers largely architecture, mural painting and sculpture, and interior decoration. (3) Cooper Union, which is divided into a Night School of Art and a Woman's Art School with an enrollment in 1927–28 of 1,446 and 337, respectively. Tuition is free, and it holds a unique position in affording instruction to students who work during the day or whose means are limited. (4) Grand Central School of Art, founded in 1924, with the object of developing a note of individuality in every pupil. The fact that this institution is associated with the well known art galleries and in its first four years became one of the largest and best known of the country is particularly significant. It is self-supporting, and in 1927 had an enrollment of 875, with a faculty of 18 instructors. (5) Pratt Institute, Brooklyn, with 53 instructors and 1,498 pupils in 1927. This school is noted particularly for its work in the applied arts.

The School of the Art Institute of Chicago exerts great influence in the Middle West, and has perhaps the largest enrollment of any art school in the United States, having 4,662 for the school year of 1927–28. More than half of these attend the evening or the Saturday school. There were 69 instructors in 1927–28, serving the five specialized departments of Drawing, Painting and Illustration, Sculpture, Design, Teacher Training and Drama.

Other large and influential schools of art are: The Art Academy of Cincinnati; The Cleveland School of Art; Maryland School of Fine and Practical Arts; Art School of the Detroit Society of Arts and Crafts; St. Louis School of Fine Arts; School of Industrial Art of the Pennsylvania Museum.

Schools of industrial art, which center their interests on design as applied to industry, as well as to the decorative arts, are gaining ground in the United States. These schools must be distinguished from the schools of the fine arts, where painting, sculpture, and architecture predominate. Sometimes the industrial arts are taught in the same schools as the fine arts, but they are designated as different departments.

In the teaching of the arts, the growing tendency in America is toward the encouragement of individual expression as distinguished from the hard, tight, or academic style. The idea is that a thorough technical training may be secured without prejudicing the minds of the students in favor of any particular creed of art, leaving them free to express their own individuality without undue influence from their instructors, whose business it is to guide and develop rather than to encourage imitation.

(F. L. D.)

GREAT BRITAIN

The opening of an art school at Somerset House, London, in 1827 was a forerunner of the many provincial schools that followed. The Exhibition of 1851, at the Crystal Palace, was of untold influence not only in Great Britain but on the Continent. France had taken the lead in the industrial arts and the exhibition of her products in London caused an awakening as to the advantages in organized training for art trades. In 1889 the Technical Instruction Act was passed and in 1897 the Royal College of Art was inaugurated, the latter being perhaps the greatest factor in the movement toward national art education. The Education Act of 1902 meant that art became a definite subject in the curriculum of English elementary and secondary education. The Burnham scales of salaries for teachers and the Pension Act of 1925 have meant a higher standard of art teaching.

Some of the important schools of art in Great Britain and Ireland are: *London*: Royal College of Art, London County Council Central School of Arts and Crafts, St. John's Wood Art Schools, Glade School at University College, School of Art of the Royal Academy; *Bristol*: University of Bristol, Merchant Venturers' College; *Edinburgh:* College of Art; *Glasgow:* School of Art, Technical College; *Liverpool*: University of Liverpool; *Manchester*: Municipal School of Art; *Cheltenham*: School of Arts and Crafts; *Derby*: School of Arts and Crafts; *Dover*: School of Art; *Dublin:* Metropolitan School of Art, Hibernian Academy of Art; *Leeds:* School of Art, Hudders' Field, Technical College; *Newcastle:* Aermstrong College; *Nottingham:* Municipal School of Art and Design; *Reading:* University College.

THE CONTINENT

France.—*Paris*: The *École Nationale des Beaux-Arts,* with departments of architecture, sculpture, painting and engraving, is free to the French and admits a limited number of foreigners. The *École Nationale des Arts Décoratifs* gives a general training in the decorative arts, with special courses in decorative paintings, decorative sculpture, tapestry and glass. The *École du Louvre* is a graduate school of the history and theory of the arts, using the collections of the Louvre for illustration and research. The *École des Hautes Etudes Urbaines* specializes in city planning and decoration, and urban administration. It is a graduate school for men. The *École Centrale d'Architecture* is a private incorporated school recognized officially as an "institution d'utilite publique." There are also in Paris many private schools of drawing and painting, the most celebrated being the *Atelier Julien* and the *Atelier L'Hôte*. The *École d'Art Animalier* of M. Navalier, for sculptors of animal life, is of high repute. The New York School of Fine and Applied Arts, directed by Professor Parsons, maintains a branch at Paris for American students, especially those who cannot speak French.

Italy.—An *Istituto di Belle Arti,* a government-controlled art school, is found at Florence, Bologna, Lucca, Modena, Naples, Palermo, Parma, Venice and Siena (provincial). In Milan, Perugia, and Ravenna similar art schools are known as *Accademia di Belle Arti.* The *Istituto Superiore di Belle Arti* is at Rome.

Spain.—There are in most of the provinces elementary schools of Arts and Crafts or Fine Arts where design and modeling are taught. The various higher institutions of learning also have art classes. Among the important schools of art in Madrid are: *Escuela especial de Pintura, Escultura y Grabado,* in Calle de Alcalá. The *Escuela Superior de Bellos Oficios* is in Barcelona.

The Netherlands.—The following are the chief schools of art: *Amsterdam:* The State Academy of Fine Arts, The Central Institute for Decorative and Industrial Arts; *The Hague:* Academy of Fine Arts; *Rotterdam*: Academy of Fine Arts and Applied Sciences; *Haarlem*: School of Architecture, Decorative Arts and Trade Arts; *Utrecht*: Museum School of Industrial Arts.

Belgium.—As an art center, Brussels has one of the largest and most active art schools of the world, the *Academie Royale des Beaux-Arts et École des Arts Decoratifs.* This school had its inception when in 1711 the Magistracy of Brussels gave a room in

the *Hotel de Ville* to the Deans of Painters, Sculptors, and Decorators to practice their art there. From this beginning it has ever since, excepting periods of war, received substantial patronage; the great families of Brussels vied with one another in giving gifts of money and of models. (X.)

Outside of Paris.—The *École Nationale des Beaux-Arts de Lyon,* at Lyons, is modeled after the one of the same name in Paris. Other Beaux-Arts schools are at Dijon and Algiers, North Africa. "Regional" schools, supported by the State, provide free instruction in industrial and decorative arts at Amiens, Clermont-Ferrand, Montpellier, Nancy, Reims, Rouen, St. Étienne and Tours. There are many "Municipal" art schools, also maintained by the State, and a few independent schools of very high rank. Four *Écoles Nationales des Arts Décoratifs,* three *Écoles Nationales Speciales,* and two Regional Schools of Industrial Art are also of interest. Information concerning the various art schools may be secured from the American University Union, Paris.

Germany and Austria.—The leading art schools of Germany are the government-managed "Kunstakademien." Of the various institutions in the individual cities, including also some "Kunstgewerbeschulen" (schools for applied art) the following may be mentioned: Berlin: *Akademische Hochschule für die bildenden Künste, Akademisches Meisteraltelier für die bildendem Künste, Preussiche Akademie der Kunst, Unterrichtsanstalt des Kunstgewerbemuseums;* Breslau: *Akademie für Kunst und Kunstgewerbe;* Dresden: *Akademie der bildenden Künste, Staatliche Akademie für Kunstgewerbe;* Frankfort: *Städtische Künstgewerbeschule;* Hamburg: *Staatliche Kunstgewerbeschule;* Hanover: *Kunstgewerblicher Unterricht für Frauen und Mädchen;* Cologne: *Kunstgewerbe und Handwerkerschule der Stadt Köln;* Leipzig: *Staatliche Akademie für graphische Künste und Buchgewerbe;* Munich: *Bayerische Akademie der bildenden Künste, Staatliche Kunstgewerbeschule München,* and *Malschule der Stadtischen Kunstgewerbeschule.* Other important art schools are at Cassel, Karlsruhe, Konigsberg, Potsdam, Stuttgart and Weimar. In Austria the *Kunstgewerbe Schule* in Vienna is of outstanding importance as well as the *Akademie der Bildenden Künste.*

SCHOPENHAUER, ARTHUR (1788–1860), German philosopher, was born at Danzig on Feb. 22, 1788, the son of a wealthy merchant, who removed to Hamburg in 1793 when the free city, for which he had the strongest patriotic feeling, surrendered to Prussia. His mother, *née* Johanna von Trosiener, who was 20 years younger than her husband, became a novelist of repute. The marriage was an unhappy one, and the two children, Arthur and Adèle, suffered in their nerves. The elder Schopenhauer wanted his children to see the world, and they spent much time in Holland, France and England.

Education.—The son's education was intermittent. He spent two years (1797–99) at Havre, four years in an elementary school at Hamburg, six months in England, and then entered a merchant's office in Hamburg. He had been there for three months when his father, who had shown signs of mental malady, fell or threw himself into the canal.

His mother settled in Weimar, where she gathered round her a small salon. Arthur left his merchant's office, and spent two years in studying the classics. In 1809 (aged 21) his mother handed over to him the third part of the paternal estate, which gave him an income of £150, and in Oct. 1809 he entered the University of Göttingen, where he read especially Plato and Kant. Among his few acquaintances were Bunsen, the subsequent scholar-diplomatist, and Bunsen's pupil, W. B. Astor. Even then he found his trustiest mate in a poodle. After two years at Göttingen he took two years at Berlin, where he heard Fichte and Schleiermacher. Here he also dipped into various fields of learning, notably into the classics under Wolf. Between 1811 and 1813 the lectures of Fichte (later published by Schopenhauer from his notes in his *Nachgelassene Werke*) dealt with what he called the "facts of consciousness" and the "theory of science," and struggled to present his final conception of philosophy. Though Schopenhauer listened usually in opposition, his speculation was undoubtedly influenced by Fichte.

In Berlin Schopenhauer was lonely and unhappy. One of his interests was to visit the Hospital La Charité and study the evidence it afforded of the interdependence of the moral and the physical in man. In the early days of 1813 sympathy with the national enthusiasm against the French carried him so far as to buy a set of arms, but no farther. He hurried away to the quiet Thuringian town of Rudolstadt, where, in the inn "Zum Ritter," he wrote, helped by books from the Weimar library, his thesis for the degree of doctor in philosophy at Jena. His first book, *Über die vierfache Wurzel des Satzes vom zureichenden Grunde* (1813), appeared at Rudolstadt. In the winter of 1813 Schopenhauer spent a few months at Weimar with his mother. But the strain of daily association was too much for their antagonistic natures. His splenetic temper and her volatility culminated in an open rupture in May 1814. From that time till her death in 1838 Schopenhauer never saw his mother again. At Weimar he made some acquaintances who influenced the course of his thought. Conversations with the orientalist, F. Mayer, directed his studies to the philosophical speculations of ancient India, made available in Friedrich Schlegel's *Language and Wisdom of the Old Hindus,* and Anquetil Duperron's version of the *Upanishads.* Most important was his contact with Goethe, who interested him in his investigations on colours. Schopenhauer took up the subject in earnest, and wrote *Über das Sehen und die Farben* (1816). The essay was written at Dresden, where he settled after the rupture with his mother. It had been sent in ms. to Goethe in the autumn of 1815, who, finding in it a transformation of his own ideas, inclined to regard the author as an opponent.

"The World as Will and Idea."—The interest of his life at Dresden was the composition of a work which should give expression in all its aspects to the idea of man's nature and destiny which had been gradually taking shape in his mind. More and more he learned from Cabanis and Helvetius to see in the will and the passions the determinants of intellectual life, and in the character and the temper the source of theories and beliefs. The conviction was borne in upon him that scientific explanation could never do more than systematize and classify the mass of appearances which to our habit-blinded eyes seem to be the reality. To get at this reality and thus to reach a standpoint higher than that of aetiology was the problem of his as of all philosophy. It is only by such a tower of speculation that an escape is possible from the spectre of materialism, theoretical and practical; and so, says Schopenhauer, "the just and good must all have this creed: I believe in a metaphysic." The mere reasonings of theoretical science leave no room for art, and practical prudence usurps the place of morality. The higher life of aesthetic and ethical activity —the beautiful and the good—can only be based upon an intuition which penetrates the heart of reality. At the end of 1818 the book appeared (with the date 1819) as *Die Welt als Wille und Vorstellung* (*The World as Will and Idea*), in four books, with an appendix containing a criticism of the Kantian philosophy (Eng. trans. by R. B. Haldane and J. Kemp, 1883). Long before the work was published Schopenhauer had rushed off to Italy. He stayed for a time in Venice, where Byron was then living, but the two did not meet; he also visited Rome, Naples and Paestum. About this time the family fortunes of his mother and sister and himself were threatened by the failure of the firm in Danzig, and Schopenhauer showed considerable business ability in saving something from the wreck.

Life at Berlin.—After some stay at Dresden he began to lecture, without much success, in Berlin. He soon abandoned the attempt, attributing his failure to Hegelian intrigues. Thus, except for some attention to physiology, the first two years at Berlin were wasted. In May 1822 he set out by way of Switzerland for Italy. After spending the winter at Florence and Rome, he left in the spring of 1823 for Munich, where he stayed for nearly a year, the prey of illness and isolation. When, at the end of this wretched time, he left for Gastein, in May 1824, he had almost entirely lost the hearing of his right ear. Dresden, which he reached in August, no longer presented the same hospitable aspect as of old, and he was reluctantly drawn onwards to Berlin in May 1825. The next six years, in Berlin, were a dismal period in the life of Schopenhauer. Hegelianism reigned in the schools and in

literature and basked in the sunshine of authority. Schopenhauer fell into morbid meditations. The sexual passion had a strong attraction for him at all times, and, according to his biographers, the notes he set down in English, when he was turned 30, on marriage and kindred topics are unfit for publication.

Life in Frankfurt.—In 1833 he settled finally at Frankfurt, gloomily waiting for the recognition of his work, and terrified by fears of assassination and robbery. As the years passed he noted down every confirmation he found of his own opinion, already expressed in *Die Welt als Wille und Vorstellung,* in the writings of others, and every instance in which his views appeared to be illustrated by new researches. He gave each *aperçu* a place in his alphabetically arranged note-book. Everything he published in later life may be called a commentary, an excursus or a scholium to his main book. Meanwhile he grew more and more embittered by the neglect of his own work and the triumph of the Hegelians. His accumulated ill-humour found vent in the wild outcry against the philosophy of the professoriate, entitled *Über den Willen in der Natur* (1836; revised and enlarged, 1854; Eng. trans., 1889). In 1841 he published, under the title *Die beiden Grundprobleme der Ethik,* two essays which he had sent in 1838–39 in competition for prizes offered by Norwegian and Danish academies of science; he was awarded the Norwegian prize but the Danish academy denied it to him, although he was the only competitor.

Final Recognition.—In 1844 appeared the second edition of *Die Welt als Wille und Vorstellung* (2 vols.). The first volume was a slightly altered reprint of the earlier issue; the second consisted of a series of chapters forming a commentary parallel to those into which the original work was now first divided. The longest of these new chapters deal with the primacy of the will, with death and with the metaphysics of sexual love. But, though only a small edition was struck off (500 copies of vol. i. and 750 of vol. ii.), the report of sales which Brockhaus rendered in 1846 was unfavourable, and the price had afterwards to be reduced. Yet there were faint indications of coming fame, and Schopenhauer welcomed eagerly each new tribute from critic and admirer. His principal admirer was Frauenstädt, who made his personal acquaintance in 1846. It was Frauenstädt who succeeded in finding a publisher for the *Parerga und Paralipomena,* which appeared at Berlin in 1851 (2 vols., pp. 465, 531; selected trans. by J. B. Saunders, 1889; French by A. Dietrich, 1909). For this bulky collection of essays, philosophical and others, Schopenhauer received as honorarium only ten free copies of the work. Soon afterwards, Dr. E. O. Lindner, assistant editor of the *Vossische Zeitung,* began a series of Schopenhauerite articles. Amongst them may be reckoned a translation by Mrs. Lindner of an article by John Oxenford which appeared in the *Westminster Review* for April 1853, entitled "Iconoclasm in German Philosophy," being an outline of Schopenhauer's system. In 1854 Frauenstädt's *Letters on the Schopenhauerean Philosophy* showed that the new doctrines were becoming a subject of discussion, and the University of Leipzig offered a prize for the best exposition and examination of the principles of Schopenhauer's system. Between 1847 and 1860 new editions of his works were called for. In 1854 Richard Wagner sent him a copy of the *Ring of the Nibelung,* with some words of thanks for a theory of music which had fallen in with his own conceptions. Schopenhauer died at Frankfurt on Sept. 21, 1860.

His Philosophic System.—More than others the philosopher leads a second life in the spirit or intellect alongside of his life in the flesh—the life of knowledge beside the life of will. It is inevitable that he should be especially struck by the points in which the sensible and temporal life comes in conflict with the intellectual and eternal. It was thus that Schopenhauer by his own experience saw in the primacy of the will the fundamental fact of his philosophy; and found in the engrossing interests of the selfish ἔρως the perennial hindrances of the higher life. For his absolute individualism, which recognizes in the State, the Church, the family only so many superficial and incidental provisions of human craft, the means of relief was absorption in the intellectual and purely ideal aims which prepare the way for the cessation of temporal individuality altogether. But theory is one thing and practice another; and he will often lay most stress on the theory who is most conscious of defects in the practice. It need not, therefore, surprise us that the man who formulated the sum of virtue in justice and benevolence was unable to be just to his own kinsfolk and reserved his compassion largely for the brutes, and that the delineator of asceticism was more than moderately sensible of the comforts and enjoyments of life. The philosophy of Schopenhauer, like almost every system of the 19th century, can hardly be understood without reference to the ideas of Kant. But in various ways a reaction arose against this absorption of everything in reason. In Fichte the source of being is primeval activity, the groundless and incomprehensible deed-action (*That-Handlung*) of the absolute ego. The innermost character of that ego is an infinitude in act and effort. "The will is the living principle of reason," he says again. "In the last resort," says Schelling (1809), in his *Inquiries into the Nature of Human Freedom,* "there is no other being but will. *Wollen ist Ursein* (will is primal being); and to this alone apply the predicates fathomless, eternal, independent of time, self-affirming." Idealism was never without a protest that there is a heart of existence, life, will, action, which is presupposed by all knowledge and is not itself amenable to explanation. We may, if we like, call this element, which is assumed as the basis of all scientific method, irrational—will instead of reason, feeling rather than knowledge.

It is under the banner of this protest against rationalizing idealism that Schopenhauer advances. But what marks out his armament is its pronounced realism. He fights with the weapons of physical doctrine and on the basis of the material earth. He knows no reason but the human, no intelligence save what is exhibited by the animals. He knows that both animals and men have come into existence within assignable limits of time, and that there was an anterior age when no eye or ear gathered the life of the universe into perceptions. Knowledge, therefore, with its vehicle, the intellect, is dependent upon the existence of certain nerve-organs located in an animal system; and its function is originally only to present an image of the interconnections of the manifestations external to the individual organism, and so to give to the individual in a partial and reflected form that feeling with other things, or innate sympathy, which it loses as organization becomes more complex and characteristic. Knowledge or intellect, therefore, is only the surrogate of that more intimate unity of feeling or will which is the underlying reality—the principle of all existence, the essence of all manifestations, inorganic and organic. And the perfection of reason is attained when man has transcended those limits of individuation in which his knowledge at first presents him to himself, when by art he has risen from single objects to universal types, and by suffering and sacrifice has penetrated to that innermost sanctuary where the euthanasia of consciousness is reached—the blessedness of eternal repose.

Schopenhauer disputes the claims of reason to priority and seeks to demonstrate the relativity and limitations of science. Science, he says, is based on final inexplicabilities; and its attempts by theories of evolution to find an historical origin for humanity in rudimentary matter show a misconception of the problem. In the successions of material states there can nowhere be an absolute first. The true origin of man, as of all else, is to be sought in an action which is everlasting and which is ever present: *nec te quaesiveris extra.* There is a source of knowledge within us by which we know, and more intimately than we can ever know anything external, that we will and feel. That is the first and the highest knowledge, the only knowledge which can strictly be called immediate; and to ourselves we as the subject of will are truly the "immediate object." It is in this sense of will—of will without motives, but not without consciousness of some sort—that reality is revealed. Analogy and experience make us assume it to be omnipresent. It is a mistake to say will means for Schopenhauer only force. It means a great deal more; and it is his contention that what the scientist calls force is really will. In so doing he is only following the line predicted by Kant (*Kritik* trans. anal., bk. ii., appendix) and anticipated by Leibniz. If we wish, said Kant, to give a real existence to the thing in itself or the noumenon we can only do so by investing it with the attributes found in our

own internal sense, viz., with thinking or something analogous thereto.

It is thus that Fechner in his "day-view" of things sees in plants and planets the same fundamental "soul" as in us—that is, "one simple being which appears to none but itself, in us as elsewhere wherever it occurs self-luminous, dark for every other eye, at the least connecting sensations in itself, upon which, as the grade of soul mounts higher and higher, there is constructed the consciousness of higher and still higher relations" (*Über die Seelenfrage*, p. 9, 1861). It is thus that Lotze declares (*Mikrokosmus*, i., 408, 2nd. ed.) that "behind the tranquil surface of matter, behind its rigid and regular habits of behaviour, we are forced to seek the glow of a hidden spiritual activity." So Schopenhauer, but in a way all his own, finds the truth of things in a will which is indeed unaffected by conscious motives and yet cannot be separated from some faint analogue of non-intellectual consciousness.

Influence Upon the World.—In two ways Schopenhauer has influenced the world. He has shown with unusual lucidity of expression how feeble is the spontaneity of that intellect which is so highly lauded, and how overpowering the sway of original will in all our action. He thus reasserted realism, whose gospel reads, "In the beginning was appetite, passion, will," and has discredited the doctrinaire belief that ideas have original force of their own. This creed of naturalism is dangerous, and it may be true that the pessimism it implies often degenerates into cynicism and a cold-blooded denial that there is any virtue and any truth. But in the crash of established creeds and the spread of political indifferentism and social distintegration it is probably wise, if not always agreeable, to lay bare the wounds under which humanity suffers, though pride would prompt their concealment. But Schopenhauer's theory has another side. If it is daringly realistic, it is no less audacious in its idealism. The second aspect of his influence is the doctrine of redemption of the soul from its sensual bonds, first by the medium of art and second by the path of renunciation and ascetic life. It may be difficult in each case to draw the line between social duty and individual perfection. But Schopenhauer reminds us that the welfare of society is a temporal and subordinate aim, never to be allowed to dwarf the full realization of our ideal being. Man's duty is undoubtedly to join in the common service of sentient beings; but his final goal is to rise above the toils and comforts of the visible creature into the vast bosom of a peaceful Nirvana.

Bibliography.—Complete works edit. by J. Frauenstädt (6 vols., Leipzig, 1873–74); with notes and introduction, M. Brasch (3rd ed., Leipzig, 1891); E. Grisebach (6 vols., Leipzig, 1892). There are many translations of special works in all languages; among English translators are R. B. Haldane, T. B. Saunders, W. M. Thompson, A. B. Bullock. *Arthur Schopenhauers handschriftlicher Nachlass* was published by Grisebach in 4 vols. (1896), from mss. in the royal library at Berlin. On Schopenhauer's life *see* Gwinner, *Schopenhauers Leben* (1878); E. Grisebach, *Schopenhauer, Geschichte seines Lebens* (1897); J. Volkelt, *Schopenhauer* (1907). A list of works is given by Balan, *Schopenhauer-Literatur* (1880); *see* also G. F. Wagner, *Encyklopädisches Register zu Schopenhauers Werken* (1909), and W. L. Hertslet, *Schopenhauer-Register* (1890). Among earlier criticisms *see:* Frauenstädt and Lindner, *A. Schopenhauer; von ihm; über ihn* (1863); Helen Zimmern, *Schopenhauer and his Philosophy* (1877); O. Busch, *A. Schopenhauer* (1878); K. Peters, *Schopenhauer als Philosoph* (1883); Koeber, *Schopenhauers Erlösungslehre* (1881), and *Die Philos. A. Schopenhauers* (1888). More recent works are: T. Whittaker, *Schopenhauer* (1909); G. Simmel, *Schopenhauer und Nietzsche* (1907); F. Paulsen, *Schopenhauer. Hamlet. Mephistopheles* (1900), three studies in pessimism; T. Lorenz, *Zur Entwickelungsgeschichte der Metaphysik Schopenhauers* (1897); Mobius, *Schopenhauer* (1899); R. Lehmann, *Schopenhauer und die Entwickelung der monistischen Weltanschauung* (1892); and *Schopenhauer. Ein Beitrag zur Psychologie der Metaphysik* (1894); Th. Ribot, *La Philosophie de Schopenhauer* (9th ed., 1903); H. Bamberger, *Das Tier in der Philosophie Schopenhauers* (1897); Kuno Fischer, *Schopenhauer* (in the *Gesch. d. neuer. Philos.*, 1893); R. Böttger, *Das Grundproblem der Schopenhauerschen Philos.* (1898); W. Caldwell, *Schopenhauer's System* (1896); O. Damm, *Schopenhauers Ethik im Verhältnis zu seiner Erkenntnislehre* (1898) and *Schopenhauers Rechts- und Staatsphilosophie* (1901); W. Hauff, *Die Überwindung des Schopenhauerschen Pessimismus durch F. Nietzsche* (1904); M. Kelly, *Kant's Ethics and Schopenhauer's criticism* (1910). (W. Wal.; X.)

SCHORL, in mineralogy the name given to coarse black varieties of tourmaline (*q.v.*). Schorl was originally a mining term applied both to black tourmaline and to hornblende.

Schorl rocks are crystalline aggregates of quartz and tourmaline and occur almost always in association with tourmaline-bearing granites or pegmatites. They originate by the action of gases and vapours on granites, porphyries and other rocks. Sometimes direct pneumatolytic derivatives of the granite itself, they are also frequent as replacement products of the country rock into which the granite is intruded. The altered granite known as *luxullianite*, from its occurrence near Luxullian, a village in Cornwall, is a tourmalinized granite in which a progressive replacement of biotite and felspar by quartz and tourmaline can be traced. The rock still contains pink felspars in large porphyritic felspars set in a dark tourmaline matrix, giving polished specimens a handsome appearance. By impregnation with boron-bearing vapours, the slates and sandstones surrounding granites are locally converted into schorl rock, schorl schist, or tourmaline hornfels consisting almost wholly of quartz and tourmaline. Banding, lamination, or cleavage of the original slates, etc., is frequently preserved in these assemblages. (*See* also Pneumatolysis.) (C. E. T.)

SCHOULER, JAMES (1839–1920), American lawyer and historian, of Scotch descent, was born in West Cambridge (now Arlington), Mass., on March 20, 1839. He graduated at Harvard in 1859, taught a year at St. Paul's school in Concord (N.H.). studied law in Boston and was admitted to the bar in 1862. His legal practice was interrupted by service in the Union Army; and in 1869 he removed to Washington, where he opened a branch office and for three years published the *United States Jurist*. After his return to Boston, he devoted himself to office practice and to literary pursuits, lecturing also at Boston university, the National University law school, Washington (D.C.), and Johns Hopkins university. In 1896–97 he was president of the American Historical Association. He died at Intervale (N.H.), on April 16, 1920. His legal publications include treatises on domestic relations (1870), bailments (1880) and wills (1887). He is best known, however, as an historian, his most important work being a *History of the United States under the Constitution 1789–1871* (7 vols., 1880–1913). Among his other publications are *Historical Briefs* (1896), which contains his biography up to that period; *Constitutional Studies* (1897); lives of Thomas Jefferson (1893) and Alexander Hamilton (1901); *Americans of 1776* (1906); and *Ideals of the Republic* (1908).

SCHREINER, OLIVE (1862–1920), pen name of Mrs. Cronwright-Schreiner, was born in Basutoland, the daughter of a German missionary. In 1882 she brought to England the ms. of her first novel *The Story of an African Farm*, a vivid and penetrating study of the life she knew well, and submitted it to George Meredith, then reader for Chapman and Hall. It was published in 1883 by this firm over the pseudonym "Ralph Iron," and proved an immediate success, entirely surpassing any of her subsequent writings in literary merit. Her later work includes *Dreams* (1891); *Trooper Peter Halkett of Mashonaland* (1897), a much-criticized attack on the first settlers in Rhodesia; *An English South African's View of the Situation* (1899); and *Woman and Labour* (1911), a fragment of an earlier ms. which had been burnt during the South African War. She died at Cape Town on Dec. 12, 1920. She had married in 1894 S. C. Cronwright, a member of the Cape parliament, who afterwards took the name of S. C. Cronwright-Schreiner. He wrote *The Life of Olive Schreiner*, which appeared in 1923.

SCHREINER, WILLIAM PHILIP (1857–1919), was born in the district of Cape Colony. After studying law at Cape Town, and at Cambridge and London universities, he was called to the bar (Inner Temple) in 1882 and on returning to South Africa in the same year was admitted as an advocate of the Cape Supreme Court. He was for many years leader of the Cape bar; in 1887 he entered Cape politics as attorney-general in the second Rhodes Ministry. He was prime minister on the outbreak of the South African War (1899). In 1914 he was appointed high commissioner for the Union in London, and he died at Llandrindod Wells, Wales, on June 28, 1919.

SCHREYER, ADOLF (1828–1899), German painter, was born at Frankfurt-on-Main on May 9, 1828. He studied art first at the Staedel Institute in his native town, and then at Stuttgart, Munich, and Düsseldorf; but he formed his style in Paris, whilst he found his favourite subjects in his travels in the Near East. In 1862 he settled in Paris, but returned to Germany in 1870; and settled at Cronberg near Frankfurt, where he died in 1899. Schreyer was especially esteemed as a painter of horses, of peasant life in Wallachia and Moldavia, and of battle incidents. His work may be seen in the Schwerin Gallery, in the collection of Count Mensdorff-Pouilly, the Ravené gallery, Berlin, the Metropolitan Museum, New York, and in the Rockefeller, Vanderbilt, J. J. Astor, W. Astor, A. Belmont, and W. Walters collections.

SCHRODER, FRIEDRICH LUDWIG (1744–1816), German actor, manager and dramatist, was born in Schwerin on Nov. 3, 1744. In 1764 he appeared with the Ackermann company (K. E. Ackermann was his stepfather) in Hamburg, playing leading comedy parts; but his most famous performances were in the tragic rôles of Hamlet, Lear and Philip in Schiller's *Don Carlos*. After Ackermann's death in 1771 Schröder and his mother took over the management of the Hamburg theatre, and he began to write plays—largely adaptations from the English, making his first success with the comedy *Die Arglistige*. In 1780 he left Hamburg, and after a tour with his wife, Anna Christina Hart, accepted an engagement at the Court theatre in Vienna. In 1785 Schröder again took over his Hamburg management and conducted the theatre with marked ability until his retirement in 1798. In 1811 he returned to it for one year. He died on Sept. 3, 1816. As an actor Schröder abandoned the stilted style of former tragedians; as a manager he first brought Shakespeare before the German public. Schröder's *Dramatische Werke*, with an introduction by Tieck, were published in four volumes (1831).

See B. Litzmann, *Friedrich Ludwig Schröder* (Hamburg, 1890–94); R. Blum in the *Allgemeines Theater-Lexikon* (1842); and Brunier, *Friedrich Ludwig Schröder* (Leipzig, 1864).

SCHUBERT, FRANZ PETER (1797–1828), Austrian composer, was born on Jan. 31, 1797, in the Himmelpfortgrund, a small suburb of Vienna. His father, Franz, son of a Moravian peasant, was a parish schoolmaster; his mother, Elizabeth Fitz, had before her marriage been cook in a Viennese family. Of their 14 children nine died in infancy. The father, a man of worth and integrity, possessed some reputation as a teacher, and his school, in the Lichtenthal, was well attended. He was also a fair musician.

At the age of five Schubert began to receive regular instruction from his father. At seven he was placed under the charge of Michael Holzer, the Kapellmeister of the Lichtenthal Church. Holzer's lessons seem to have consisted mainly in expressions of admiration, and the boy gained more from a friendly joiner's apprentice, who used to take him to a neighbouring pianoforte warehouse and give him the opportunity of practising on a better instrument than the poor home could afford.

In Oct. 1808 he was received as a scholar at the Convict, which, under Salieri's direction, had become the chief music-school of Vienna, and which had the special office of training the choristers for the Court Chapel. Here he remained until nearly 17, profiting little by the direct instruction, which was almost as careless as that given to Haydn at St. Stephen's, but much by the practices of the school orchestra, and by association with congenial comrades. Many of the most devoted friends of his after life were among his schoolfellows: Spaun and Stadler and Holzapfel, and a score of others who helped him out of their slender pocket-money, bought him music-paper which he could not buy for himself, and gave him loyal support and encouragement.

EARLY COMPOSITIONS

Meanwhile his genius was already showing itself in composition. A pianoforte fantasia, 32 close-written pages, is dated April 8–May 1, 1810: then followed in 1811, three long vocal pieces written upon a plan which Zumsteeg had popularized, together with a "quintet-overture," a string quartet, a second pianoforte fantasia and a number of songs. His essay in chamber-music is noticeable, since we learn that at the time a regular quartet-party was established at his home "on Sundays and holidays," in which his two brothers played the violin, his father the violoncello and Franz himself the viola. It was the first germ of that amateur orchestra for which, in later years, many of his compositions were written. During the remainder of his stay at the Convict he wrote a good deal more chamber-music, several songs, some miscellaneous pieces for the pianoforte and, among his more ambitious efforts, a *Kyrie* and *Salve Regina*, an octet for wind instruments—said to commemorate the death of his mother, which took place in 1812—a cantata, words and music, for his father's name-day in 1813, and the closing work of his school-life, his first symphony.

At the end of 1813 he left the Convict, and, to avoid military service, entered his father's school as teacher of the lowest class. For over two years he endured the drudgery of the work, which, we are told, he performed with very indifferent success. There were, however, other interests to compensate. He took private lessons from Salieri, who annoyed him with accusations of plagiarism from Haydn and Mozart, but who did more for his training than any of his other teachers; he occupied every moment of leisure with rapid and voluminous composition. His first opera—*Des Teufels Lustschloss*—and his first Mass—in F major—were both written in 1814, and to the same year belong three string quartets, many smaller instrumental pieces, the first movement of the symphony in B flat and 17 songs, including such masterpieces as *Der Taucher* and *Gretchen am Spinnrade*. But even this activity is far outpaced by that of the *annus mirabilis* 1815. In this year, despite his school-work, his lessons with Salieri and the many distractions of Viennese life, he produced an amount of music the record of which is almost incredible. The symphony in B flat was finished, and a third, in D major, added soon afterwards. Of church music there appeared two Masses, in G and B flat, the former written in six days, a new *Dona nobis* for the Mass in F, a *Stabat Mater* and a *Salve Regina*. Opera was represented by no fewer than five works, of which three were completed—*Der Vierjährige Posten, Fernando* and *Claudine von Villabella*—and two, *Adrast* and *Die beiden Freunde von Salamanca*, apparently left unfinished. Besides these the list includes a string quartet in G minor, four sonatas and several smaller compositions for piano, and, by way of climax, 146 songs, some of which are of considerable length, and of which eight are dated Oct. 15, and seven Oct. 19.

In the winter of 1814–15 Schubert made acquaintance with the poet Mayrhofer: an acquaintance which, according to his usual habit, soon ripened into a warm and intimate friendship. They were singularly unlike in temperament: Schubert frank, open and sunny, with brief fits of depression, and sudden outbursts of boisterous high spirits; Mayrhofer grim and saturnine, a silent man who regarded life chiefly as a test of endurance.

As 1815 was the most prolific period of Schubert's life, so 1816 saw the first real change in his fortunes. Somewhere about the turn of the year Spaun surprised him in the composition of *Erlkönig*—Goethe's poem propped among a heap of exercise-books, and the boy at white-heat of inspiration "hurling" the notes on the music-paper. A few weeks later Von Schober, a law-student of good family and some means, who had heard some of Schubert's songs at Spaun's house, came to pay a visit to the composer and proposed to carry him off from school-life and give him freedom to practise his art in peace. The proposal was particularly opportune, for Schubert had just made an unsuccessful application for the post of Kapellmeister at Laibach, and was feeling more acutely than ever the slavery of the class-room. His father's consent was readily given, and before the end of the spring he was installed as a guest in Von Schober's lodgings. For a time he attempted to increase the household resources by giving music lessons, but they were soon abandoned and he devoted himself to composition. "I write all day," he said later to an inquiring visitor, "and when I have finished one piece I begin another."

The works of 1816 include three ceremonial cantatas and two new symphonies, No. 4 in C minor, called the *Tragic*, with a striking andante, No. 5 in B flat, as bright and fresh as a symphony of Mozart; some numbers of church music, fuller and more

mature than any of their predecessors, and over a hundred songs, among which are comprised some of his finest settings of Goethe and Schiller. There is also an opera, *Die Burgschaft,* spoiled by an illiterate book.

All this time his circle of friends was steadily widening. Mayrhofer introduced him to Vogl, the famous baritone, who did him good service by performing his songs in the salons of Vienna; Anselm Hüttenbrenner and his brother Joseph ranged themselves among his most devoted admirers; Gahy, an excellent pianist, played his sonatas and fantasias; the Sonnleithners, a rich burgher family whose eldest son had been at the Convict, gave him free access to their home, and organized in his honour musical parties which soon assumed the name of Schubertiaden. The material needs of life were supplied without much difficulty. No doubt Schubert was entirely penniless, for he had given up teaching, he could earn nothing by public performance, and, as yet, no publisher would take his music at a gift; but his friends came to his aid with true Bohemian generosity—one found him lodging, another found him appliances, they took their meals together and the man who had any money paid the score. Schubert was always the leader of the party and was known by half-a-dozen affectionate nicknames, of which the most characteristic is *"kann er 'was?"* his usual question when a new acquaintance was proposed.

The year 1818, though, like its predecessor, comparatively unfertile in composition, was in two respects a memorable year. It saw the first public performance of any work of Schubert's—an overture in the Italian style written as an avowed burlesque of Rossini, and played in all seriousness at a Jäll concert on March 1. It also saw the beginning of his only official appointment, the post of music-master to the family of Count Johann Esterhazy at Zelesz, where he spent the summer amid pleasant and congenial surroundings. On his return to Vienna in the autumn he found that Von Schober had no room for him, and took up his residence with Mayrhofer. He made his first public appearance as a songwriter on Feb. 28, 1819, when the *Schäfers Klagelied* was sung by Jäger at a Jäll concert. In the summer of the same year he took a holiday and travelled with Vogl through Upper Austria. At Steyr he wrote his brilliant piano quintet in A, and astonished his friends by transcribing the parts without a score. In the autumn he sent three of his songs to Goethe, but, so far as we know, received no acknowledgment.

MATURITY

The compositions of 1820 are remarkable, and show a great advance in development and maturity of style. The unfinished oratorio *Lazarus* was begun in Feb.; later followed, amid a number of smaller works, the 23rd Psalm, the *Gesang der Geister,* the quartettsatz in C minor and the great pianoforte fantasia on *Der Wanderer.* But of almost more biographical interest is the fact that in this year two of Schubert's operas appeared at the Kärnthnerthor theatre, *Die Zwillingsbrüder* on June 14, and *Die Zauberharfe* on Aug. 19. Still, however, publishers held obstinately aloof, and it was not until his friend Vogl had sung *Erlkönig* at a concert in the Kärnthnerthor (Feb. 8, 1821) that Diabelli hesitatingly agreed to print some of his works on commission. The first seven opus-numbers (all songs) appeared on these terms; then the commission ceased, and he began to receive the meagre pittances which were all that the great publishing houses ever accorded to him. Much has been written about the neglect from which he suffered during his lifetime. It was not the fault of his friends, it was only indirectly the fault of the Viennese public; the persons most to blame were the cautious intermediaries who stinted and hindered him from publication.

The production of his two dramatic pieces turned Schubert's attention more firmly than ever in the direction of the stage; and towards the end of 1821 he set himself on a course which for nearly three years brought him continuous mortification and disappointment. *Alfonso und Estrella* was refused, so was *Fierrabras; Die Verschworenen* was prohibited by the censor (apparently on the ground of its title); *Rosamunde* was withdrawn after two nights, owing to the badness of its libretto. Of these works the two former are written on a scale which would make their performances exceedingly difficult (*Fierrabras,* for instance, contains over 1,000 pages of manuscript score), but *Die Verschworenen* is a bright, attractive comedy, and *Rosamunde* contains some of the most charming music that Schubert ever composed. In 1822 he made the acquaintance both of Weber and of Beethoven, but little came of it in either case, though Beethoven cordially acknowledged his genius. Von Schober was away from Vienna; new friends appeared of a less desirable character; on the whole these were the darkest years of his life.

In the spring of 1824 he wrote the magnificent octet, "A Sketch for a Grand Symphony"; and in the summer went back to Zelesz, when he became attracted by Hungarian idiom, and wrote the *Divertissement à l'Hongroise* and the string quartet in A minor. Most of his biographers insert here a story of his hopeless passion for his pupil Countess Caroline Esterhazy; but whatever may be said as to the general likelihood of the romance, the details by which it is illustrated are apocryphal, and the song *l'Addio,* placed at its climax, is undoubtedly spurious. A more debatable problem is raised by the grand duo in C major (op. 140) which is dated from Zelesz in the summer of this year. It bears no relation to the style of Schubert's pianoforte music, it is wholly orchestral in character, and it may well be a transcript or sketch of the "grand symphony" for which the octet was a preparation. If so, it settles the question, raised by Sir George Grove, of a "symphony in C major" which is not to be found among Schubert's orchestral scores.

Despite his preoccupation with the stage and later with his official duties he found time during these years for a good deal of miscellaneous composition. The Mass in A flat was completed and the exquisite "Unfinished Symphony" begun in 1822. The *Müllerlieder,* and several other of his best songs, were written in 1825; to 1824, beside the works mentioned above, belong the variations on *Trockne Blumen* and the two string quartets in E and E flat. There is also a sonata for piano and arpeggione, an interesting attempt to encourage a cumbersome and now obsolete instrument.

The mishaps of the recent years were compensated by the prosperity and happiness of 1825. Publication had been moving more rapidly; the stress of poverty was for a time lightened; in the summer there was a pleasant holiday in Upper Austria, where Schubert was welcomed with enthusiasm. It was during this tour that he produced his "Songs from Sir Walter Scott," and his piano sonata in A minor (op. 42), the former of which he sold to Artaria for £20, the largest sum which he had yet received for any composition. Sir George Grove, on the authority of Randhartinger, attributes to this summer a lost "Gastein" symphony which is possibly the same work as that already mentioned under the record of the preceding year.

From 1826 to 1828 Schubert resided continuously in Vienna, except for a brief visit to Graz in 1827. The history of his life during these three years is little more than a record of his compositions. The only events worth notice are that in 1826 he applied for a conductorship at the opera, and lost it by refusing to alter one of his songs at rehearsal, and that in the spring of 1828 he gave, for the first and only time in his career, a public concert of his own works. But the compositions themselves are a sufficient biography. The string quartet in D minor, with the variations on the song *Der Tod und das Mädchen,* was written during the winter of 1825–26, and first played on Jan. 25. Later in the year came the string quartet in G major, the "Rondeau brilliant," for piano and violin, and the fine sonata in G which, by some pedantry of the publisher's, is printed without its proper title. To these should be added the three Shakespearian songs, of which *Hark! Hark! the Lark* and *Who is Sylvia?* were written on the same day, the former at a tavern where he broke his afternoon's walk, the latter on his return to his lodging in the evening. In 1827 he wrote the *Winterreise* songs, the fantasia for piano and violin, and the two piano trios; in 1828 the *Song of Miriam,* the C major symphony, the Mass in E flat, and the exceedingly beautiful *Tantum Ergo* in the same key, the string quintet, the second Benedictus to the Mass in C, the last three piano sonatas, and the collection of songs known as *Schwanengesang.* Six of these

are to words by Heine, whose *Buch der Lieder* had recently appeared. Everything pointed to the renewal of an activity which should equal that of his greatest abundance, when he was suddenly attacked by typhus fever, and after a fortnight's illness died on Nov. 19 at the house of his brother Ferdinand. He had not completed his 32nd year.

HIS ACHIEVEMENT

Some of his smaller pieces were printed shortly after his death, but the more valuable seem to have been regarded by the publishers as waste paper. In 1838 Schumann, on a visit to Vienna, found the dusty manuscript of the C major symphony and took it back to Leipzig, where it was performed by Mendelssohn and celebrated in the *Neue Zeitschrift*. The most important step towards the recovery of the neglected works was the journey to Vienna which Sir George Grove and Sir Arthur Sullivan made in the autumn of 1867. The travellers rescued from oblivion seven symphonies, the *Rosamunde* music, some of the Masses and operas, some of the chamber works, and a vast quantity of miscellaneous pieces and songs. Their success gave impetus to a widespread public interest and finally resulted in the definitive edition of Breitkopf and Härtel.

Schubert is best summed up in the well-known phrase of Liszt, that he was "le musicien le plus poète qui fut jamais." In clarity of style he was inferior to Mozart, in power of musical construction he was far inferior to Beethoven, but in poetic impulse and suggestion he is unsurpassed. He wrote always at headlong speed, he seldom blotted a line, and the greater part of his work bears, in consequence, the essential mark of improvisation: it is fresh, vivid, spontaneous, impatient of restraint, full of rich colour and of warm imaginative feeling. He was the greatest song-writer who ever lived, and almost everything in his hand turned to song. In his Masses, for instance, he seems to chafe at the contrapuntal numbers and pours out his whole soul on those which he found suitable for lyrical treatment. In his symphonies the lyric and elegiac passages are usually the best, and the most beautiful of them all is, throughout its two movements, lyric in character. The standpoint from which to judge him is that of a singer who ranged over the whole field of musical composition and everywhere carried with him the artistic form which he loved best.

Like Mozart, whose influence over him was always considerable, he wrote nearly all the finest of his compositions in the last ten years of his life. His early symphonies, his early quartets, even his early Masses, are too much affected by a traditional style to establish an enduring reputation. It is unfair to call them imitative, but at the time when he wrote them he was saturated with Mozart, and early Beethoven, and he spoke what was in his mind with a boy's frankness. The andante of the Tragic symphony (No. 4) strikes a more distinctive note, but the fifth is but a charming adaptation of a past idiom, and the sixth, on which Schubert himself placed little value, shows hardly any appreciable advance. It is a very different matter when we come to the later works. The piano quintet in A major (1819) may here be taken as the turning-point; then come the Unfinished symphony, which is pure Schubert in every bar; the three quartets in A minor, D minor and G major, full of romantic colour; the delightful piano trios; the great string quintet; and the C major symphony which, though diffuse, contains many passages of surpassing beauty.

His larger operas are marred both by their inordinate length and by their want of dramatic power. The slighter comedies are pretty and tuneful, but, except as curiosities, are not likely to be revived. We may, however, deplore the fate which has deprived the stage of the *Rosamunde* music. It is in Schubert's best vein; the *entr'actes*, the romance, and the ballets are alike excellent, and it is much to be hoped that a poet will some day arise and fit the music to a new play.

Of his pianoforte compositions, the sonatas, as might be expected, are the least enduring, though there is not one of them which does not contain some first-rate work. On the other hand his smaller pieces, in which the lyric character is more apparent, are throughout interesting to play and extremely pleasant to hear. A special word should be added on his fondness for piano duets, a form which before his time had been rarely attempted.

His concerted pieces for the voice are often extremely difficult, but they are of a rare beauty which would well repay the labour of rehearsal.

Of the songs it is impossible, within the present limits, to give even a sketch. They number over 600, excluding scenas and operatic pieces, and they contain masterpieces from the beginning of his career to the end. *Gretchen am Spinnrade* was written when he was 17, *Erlkönig* when he was 18; then there follows a continuous stream which never checks or runs dry, and which broadens as it flows to the *Müllerlieder*, the Scott songs, the Shakespearian songs, the *Winterreise*, and the *Schwanengesang*. He is said to have been undiscriminating in his choice of words. Schumann declared that "he could set a handbill to music," and there is no doubt that he was inspired by any lyric which contained, though even in imperfect expression, the germ of a poetic idea. But his finest songs are almost all to fine poems. He set over 70 of Goethe's, over 60 of Schiller's.

In his earlier songs he is more affected by the external and pictorial aspect of the poem; in the later ones he penetrates to the centre and seizes the poetic conception from within. But in both alike he shows a gift of absolute melody which, even apart from its meaning, would be inestimable. Neither Händel nor Mozart—his two great predecessors in lyric tune—have surpassed or even approached him in fertility and variety of resource. The songs in *Acis* are wonderful; so are those in *Zauberflöte*, but they are not so wonderful as *Litanei*, and *Who is Sylvia?* and the *Ständchen*. To Schubert we owe the introduction into music of a particular quality of romance, a particular "addition of strangeness to beauty"; and so long as the art remains his place among its supreme masters is undoubtedly assured.

SCHÜCKING, WALTER (1875–), German jurist, was born on Jan. 6, 1875, at Munster, Westphalia. He taught at the universities of Breslau and Marburg 1900–21, and in 1921 was appointed a professor at the Berlin commercial high school. In 1919 he was appointed a member of the National Assembly and chief German delegate to the Peace Conference at Versailles. In 1919 he became a member of the permanent court of arbitration at The Hague. In 1920 and again in 1924 he was elected to the Reichstag and became one of the leaders of the German Democratic party.

His works include: *Das Küstenmeer im internationalen Recht* (1897), "Die Verwendung von Minem im Seekrieg" (in Niemeyer's *Zeitschrift*, vol. 16), *Die Organisation der Welt* (2nd ed. 1909), *Der Staatenverband der Haager Conferenzen* (1912) (Eng. trans. 1918), *Neue Ziele der staatlichen Entwicklung* (3rd ed. 1913), *Internationale Rechtsgarantien* (Hamburg, 1918), *Die Satzung des Volkerbundes* (2nd ed. 1924), *Garantiepakt und Rüstungsbeschrankung* (1924), *Das Genfer Protokoll* (1924).

SCHULZE-DELITZSCH, FRANZ HERMANN (1808–1883), German economist, was born at Delitzsch, in Prussian Saxony, on Aug. 29, 1808. The suffix Delitzsch was added in 1848 to distinguish him from other Schulzes in the National Assembly. He studied law at Leipzig and Halle, became an assessor in the court of justice at Berlin in 1838, and three years later was appointed *patrimonialrichter* at Delitzsch. Entering the parliament of 1848, he joined the Left Centre, and, acting as president of the commission of inquiry into the condition of the labourers and artisans, became impressed with the necessity of co-operation to enable the smaller tradespeople to hold their own against the capitalists. He was a member of the Second Chamber in 1848–49; but a quarrel with the minister of justice led him to throw up his public appointments in October 1851, and withdraw to

Delitzsch. Here he devoted himself to the organization of co-operative societies, and of Vorschussvereine (people's banks). In 1859 he promoted the first *Genossenschaftstag,* or co-operative meeting, in Weimar, and founded a central bureau of co-operative societies. In 1861 he again entered the Prussian Chamber. The next few years were given to the formation of local centres, and the establishment of the Deutsche Genossenschafts-Bank, 1865.

The spread of these organizations led to legislation on the subject, and this too was chiefly the work of Schulze-Delitzsch. As a member of the Chamber in 1867 he was mainly instrumental in passing the Prussian law of association, which was extended to the North German Confederation in 1868, and later to the empire. Schulze-Delitzsch also contributed to uniformity of legislation throughout the states of Germany, in 1869, by the publication of *Die Gesetzgebung über die privatrechtliche Stellung der Erwerbs- und Wirthschaftsgenossenschaften,* etc. His remaining years were spent in consolidating his work. He died on April 29, 1883, at Potsdam.

His works include: *Kapitel zu einem deutschen Arbeiter-Katechismus* (1863); *Soziale Rechte und Pflichten* (1867); and *Die Entwicklung des Genossenschaftswesen in Deutschland* (1870). *See* also A. Bernstein, *Schulze-Delitzsch* (1879); B. Rampal, *Esquisse Biographique* (1874).

SCHUMANN, ROBERT ALEXANDER (1810–1856), German musical composer, was born on June 8, 1810, in Zwickau, Saxony, the son of a publisher. He tells us that he began to compose before his seventh year. At fourteen he wrote an essay on the aesthetics of music and also contributed to a volume edited by his father, entitled *Portraits of Famous Men.* While still at school in Zwickau he read, besides Schiller and Goethe, Byron (whose *Beppo* and *Childe Harold* had been translated by his father) and the Greek tragedians. But the most powerful and permanent of the literary influences exercised upon him, however, was that of Jean Paul Richter. This influence may clearly be seen in his youthful novels *Juniusabende* and *Selene,* of which the first only was completed (1826). In 1828 he left school, and after a tour, during which he met Heine at Munich, he went to Leipzig to study law. His interest in music had been stimulated when he was a child by hearing Moscheles play at Carlsbad, and in 1827 by the works of Schubert and Mendelssohn. But his father, who had encouraged the boy's musical aspirations, had died in 1826, and neither his mother nor his guardian approved of a musical career for him. Nevertheless, both at Leipzig and at Heidelberg, whither he went in 1829, he neglected the law for the philosophers, and began composing songs. At Easter 1830 he heard Paganini at Frankfurt. In December 1830 he returned to Leipzig, taking piano lessons with his old master, Friedrich Wieck. In his haste to acquire a perfect execution he permanently injured his right hand. His ambitions as a pianist being thus suddenly ruined, he began a course of theory under Heinrich Dorn, conductor of the Leipzig opera. About this time he contemplated an opera on the subject of *Hamlet.*

The fusion of the literary idea with its musical illustration, which may be said to have first taken shape in *Papillons* (op. 2), is foreshadowed in an essay on Chopin's variations on a theme from *Don Juan,* which appeared in the *Allgemeine musikalische Zeitung* in 1831. Here the work is discussed by the imaginary characters Florestan and Eusebius (the counterparts of Vult and Walt in Jean Paul's novel *Flegeljahre*), and Meister Raro (representing either the composer himself or Wieck) is called upon for his opinion. By the time, however, that Schumann had written *Papillons* (1831) he had gone a step farther. The scenes and characters of his favourite novelist had now passed definitely and consciously into the written music, and in a letter from Leipzig (April 1832) he bids his brothers "read the last scene in Jean Paul's *Flegeljahre* as soon as possible, because the *Papillons* are intended as a musical representation of that masquerade." In the winter of 1832 Schumann visited his relations at Zwickau and Schneeberg, when the first movement of his symphony in G minor was performed. In Zwickau the music was played at a concert given by Wieck's daughter Clara, then only thirteen. The death of his brother Julius and of his sister-in-law Rosalie in 1833 affected Schumann with profound melancholy. By the spring of 1834, however, he started *Die neue Zeitschrift für Musik,* the paper in which appeared the greater part of his critical writings. The journal effected a revolution in the taste of the time, when Mozart, Beethoven and Weber were neglected, and the genius of Chopin and of Berlioz unappreciated.

During the the summer of 1834, Schumann became engaged to Ernestine von Fricken, a girl of sixteen, the adopted daughter of a rich Bohemian, from whose variations on a theme in C♯ minor Schumann constructed his own *Études symphoniques.* The engagement was broken off by Schumann, for reasons which have always remained obscure. In the *Carnaval* (op. 9=1834), Schumann commenced nearly all the sections with the musical notes signified in German by the letters that spell Asch, the town in which Ernestine was born, which also are the musical letters in Schumann's own name. By the sub-title "Estrella" to one of the sections in the *Carnaval,* Ernestine is meant, and by the sub-title "Chiarina" Clara Wieck. In the *Carnaval* Schumann went farther than in *Papillons,* for in it he himself conceived the story of which it was the musical illustration. On Oct. 3, 1835, Schumann met Mendelssohn at Wieck's house in Leipzig, and his appreciation of his great contemporary was shown with the generous freedom that distinguished him in all his relations to other musicians.

In 1836 Schumann's acquaintance with Clara Wieck, already famous as a pianist, ripened into love, and a year later he asked her father's consent to their marriage, but was met with a refusal. The series of *Phantasiestücke* for the piano (op. 12) once more illustrates the fusion of literary and musical ideas as embodied conceptions in such pieces as "Warum" and "In der Nacht." In the *Kreisleriana,* written in 1838, the composer's realism is again carried a step farther. Kreisler, the romantic poet brought into contact with the real world, was a character drawn from life by the poet E. T. A. Hoffmann (*q.v.*), and Schumann used him as a mouthpiece for the recital in music of his own personal experiences. The *Phantasie* (op. 17), written in the summer of 1836, is a work of the highest quality of passion. With the *Faschingschwank aus Wien,* his most pictorial work for the piano, written in 1839, after a visit to Vienna, this period of his life comes to an end. As Wieck still withheld his consent to their marriage, Robert and Clara dispensed with it, and were married on Sept. 12 at Schönefeld, near Leipzig.

Until now Schumann had written almost solely for the pianoforte, but in 1840 he wrote about a hundred and fifty songs. Schumann's biographers represent him as caught in a tempest of song, the sweetness, the doubt and the despair of which are all to be attributed to varying emotions aroused by his love for Clara. Yet it would be idle to ascribe to this influence alone the lyrical perfection of "Frühlingsnacht," "Im wunderschönen Monat Mai" and "Schöne Wiege meiner Leiden." His chief song-cycles of this period were his settings of the *Liederkreis* of J. von Eichendorff (op. 39), the *Frauenliebe und Leben* of Chamisso (op. 42), the *Dichterliebe* of Heine (op. 48) and *Myrthen,* a collection of songs, including poems by Goethe, Rückert, Heine, Byron, Burns and Moore. The songs "Belsatzar" (op. 57) and "Die beiden Grenadiere" (op. 49), each to Heine's words, show Schumann at his best as a ballad writer, though the dramatic ballad is less congenial to him than the introspective lyric. As Grillparzer said, "He has made himself a new ideal world in which he moves almost as he wills." But in his lifetime the sole tokens of honour bestowed upon Schumann were the degree of Doctor by the University of Jena in 1840, and in 1843 a professorship in the Conservatorium of Leipzig. In 1841 he wrote two of his four symphonies. The year 1842 was devoted to the composition of chamber music, and includes the pianoforte quintet (op. 44). In 1843 he wrote *Paradise and the Peri,* his first essay at concerted vocal music. He had now mastered the separate forms, and from this time forward his compositions are not confined during any particular period to any one of them. In Schumann, above all musicians, the acquisition of technical knowledge was closely bound up with the growth of his own experience and the impulse to express it. The stage in his life when he was deeply engaged in

his music to Goethe's *Faust* (1844–1853) was a critical one for his health. The first half of the year 1844 had been spent with his wife in Russia. On returning to Germany he had abandoned his editorial work, and left Leipzig for Dresden, where he suffered from persistent nervous prostration. As soon as he began to work he was seized with fits of shivering, and an apprehension of death which was exhibited in an abhorrence for high places, for all metal instruments (even keys) and for drugs. He suffered perpetually also from imagining that he had the note A sounding in his ears. In 1846 he had recovered, and in the winter revisited Vienna, travelling to Prague and Berlin in the spring of 1847 and in the summer to Zwickau.

To 1848 belongs his only opera, *Genoveva.* It is interesting for its attempt to abolish the recitative, which Schumann regarded as an interruption to the musical flow. The music to Byron's *Manfred* is pre-eminent in a year (1849) in which he wrote more than in any other. The insurrection of Dresden caused Schumann to move to Kreischa, a village near the city. In August, on the occasion of the centenary of Goethe's birth, such scenes of Schumann's *Faust* as were already completed were performed in Dresden, Leipzig and Weimar, Liszt as always giving unwearied assistance and encouragement. The rest of the work was written in the latter part of the year, and the overture in 1853. From 1850 to 1854 the text of Schumann's works is extremely varied. In 1850 he succeeded Ferdinand Hiller as musical director at Düsseldorf; in 1851–1853 he visited Switzerland and Belgium as well as Leipzig. In January 1854 Schumann went to Hanover, where he heard a performance of his *Paradise and the Peri.* Soon after his return to Düsseldorf, a renewal of the symptoms that had threatened him before showed itself. Besides the single note he now imagined that voices sounded in his ear. One night he suddenly left his bed, saying that Schubert and Mendelssohn had sent him a theme which he must write down, and on this theme he wrote five variations for the pianoforte, his last work. On Feb. 27 he threw himself into the Rhine. He was rescued by some boatmen, and taken to a private asylum in Endenich near Bonn, where he remained until his death on July 29, 1856.

His wife, Clara Schumann (1819–1896), extended her own reputation as a pianist beyond the borders of Germany, and it was thanks to her efforts that Schumann's compositions became generally known in Europe. From 1865 onward she was a regular visitor in London. In 1878 she was appointed teacher of the piano at the Hoch Conservatorium at Frankfurt, a post which she held until 1892, and in which she contributed greatly to the modern improvement in technique. As an artist she is remembered, together with Joseph Joachim, as one of the first executants who really played like composers. She was herself the composer of a few songs and of some charming music, mainly for the piano, and the authoritative editor of her husband's works for Breitkopf and Härtel.

The following are the chief compositions of Robert Schumann.

Pianoforte Works.

Papillons (op. 2)	1829–31
Études symphoniques (op. 13)	1834
Carnaval (op. 9)	1834–35
Sonata in F sharp minor (op. 11)	1835
Sonata in G minor (op. 22)	1833–35
Kinderszenen (op. 15)	1836
Fantasia in C (op. 17)	1836
Fantasiestücke (op. 12)	1837
Kreisleriana (op. 16)	1838
Novelletten (op. 21)	1838
Faschingschwank aus Wien (op. 26)	1839

Songs and Choral Works

Songs:—"Liederkreis" (Heine), nine songs (op. 24)	
"Myrthen," twenty-six songs (4 books) (op. 25)	
"Liederkreis" (Eichendorff), twelve songs (op. 39)	
"Frauenliebe und Leben" (Chamisso), eight songs (op. 42)	1840
"Dichterliebe," sixteen songs from Heine's *Buch der Lieder* (op. 48)	
"Belsatzar," ballad (Heine) (op. 57)	
Song, "Tragödie" (Heine) from op. 64	1841
Ballad, "Der Handschuh" (Schiller)	probably 1851
Songs from Wilhelm Meister and Requiem for Mignon for chorus (op. 98)	1849
Spanische Liebeslieder (op. 138)	1849
Choral and Dramatic Works:—"Paradise and the Peri," for solos, chorus and orchestra (op. 50)	1843
Faust music	1844–1853
"Genoveva," opera	1848
Manfred music	1849
"Der Rose Pilgerfahrt" (Moritz Horn), for solos, chorus and orchestra (op. 112)	
"Der Königssohn" (Uhland), for solos, chorus and orchestra (op. 103)	1851
"Des Sängers Fluch" (Uhland) for solos, chorus and orchestra (op. 139)	
Mass for four part chorus and orchestra (op. 148)	1852
"Vom Pagen und der Königstochter," four ballads (Geibel) for solos, chorus and orchestra (op. 135)	
"Das Glück von Edenhall," ballad (Uhland), for solos, chorus and orchestra (op. 143)	
Festival overture on the *Rheinweinlied* for orchestra and chorus (op. 123)	1853

Chamber Music

Three quartets for strings in A minor, F and A (op. 41)	
Quintet for pianoforte and strings in E flat (op. 44)	
Quartet for pianoforte and strings in E flat (op. 47)	1842
Fantasiestücke for pianoforte, violin and violoncello (op. 88)	
Andante and variations for two pianofortes (op. 46)	1843
Trio for pianoforte and strings in D minor (op. 63)	1847
Trio for pianoforte and strings in F (op. 80)	
Fantasiestücke for clarinet and pianoforte (op. 73)	
Five "Stücke im Volkston" for piano and violoncello (op. 102)	1849
Three Romances for oboe and piano (op. 94)	
"Märchenbilder" for pianoforte and viola (op. 113)	
Sonata for pianoforte and violin in A minor (op. 105)	
Trio for pianoforte and strings in G minor (op. 110)	1851
Sonata for pianoforte and violin in D minor (op. 121)	
"Märchenerzählungen," four pieces for clarinet, viola and pianoforte, probably written in	1853

Orchestral Works

B flat Symphony (op. 38)	
Fourth Symphony in D minor (op. 120)	1841
Overture, Scherzo and Finale	
Second Symphony in C (op. 61)	1846
Third or "Rhenish" Symphony in E flat (op. 97)	1850

Concertos and Concert-Stücke

For Pianoforte in A minor (op. 54)	1841–1845
Concert-stück for four horns (op. 86)	
Introduction and Allegro-appassionato for Pianoforte (op. 92)	1849
Concerto for Violoncello (op. 126)	1852

Fuller Maitland, *Schumann* ("Great Musicians" series); *The Life of Robert Schumann told in his Letters* (with a preface by J. G. Jansen), translated from the German by May Herbert (1902); *Letters of R. Schumann,* edited by Karl Storck (Eng. trans. by Hannah Bryant, 1907); V. Joss, *Der Musikpädagoge Friedrich Wieck und seine Familie;* Litzmann, *Clara Schumann* (1902); Moser's *Joseph Joachim* (trans., 1901; new ed., 1908) and the first volume of Kalbeck's *Brahms* (4 vols., 1904–14) contain much that is important as to Schumann's later years. *See* also Grove's *Dictionary of Music and Musicians* (1928).

SCHUMANN-HEINK, ERNESTINE (1861–), contralto, was born at Leiben, near Prague, June 15, 1861. After making her début as Azucena, Oct. 13, 1878, at the Court theatre, Dresden, she was engaged at the Stadt theatre, Hamburg, where she remained until she went to the Royal theatre, Berlin. After appearing with success at Bayreuth, in 1896, she made her American début in *Lohengrin,* at Chicago in 1898. Her London début was at Covent Garden, in *Das Rheingold,* 1902.

See Mary Lawton, *Schumann-Heink* (1929).

SCHURMAN, JACOB GOULD (1854–), American educationalist and diplomat, was born at Freetown, Prince Edward island, on May 22, 1854, of Dutch descent, his loyalist ancestors having left New York in 1784. He secured his B.A. and M.A. degrees at the University of London (1877 and 1878) and studied for several years in Paris, Edinburgh and Germany, where he met Andrew D. White. He was professor of English literature, political

economy and psychology in Acadia college in 1880–82, of metaphysics and English literature at Dalhousie college, Halifax (N.S.), in 1882–86, and of philosophy at Cornell university in 1886–92, being dean of the Sage school of philosophy in 1891–92 and president of the university from 1892 until 1920. Like his predecessor, Andrew D. White, he united a diplomatic with an educational career. He was president of the first United States Philippine Commission in 1899, minister to Greece and Montenegro in 1912–13, and minister to China from 1921 until 1925, when he was appointed ambassador to Germany. In addition to editing the *Philosophical Review*, which he founded in 1892 with J. E. Creighton and James Seth, he wrote *Kantian Ethics and the Ethics of Evolution* (1881), *The Ethical Importance of Darwinism* (1888), *Belief in God* (1890), *Agnosticism and Religion* (1896), *The Balkan Wars, 1912–1913* (1914) and *Why America Is in the War* (1917).

SCHURZ, CARL (1829–1906), German-American statesman and reformer, was born in Liblar, near Cologne, on March 2, 1829, the son of a school-teacher. He studied in the Jesuit gymnasium of Cologne in 1840–46, and then entered the University of Bonn, where he became a revolutionary and assisted Gottfried Kinkel professor of literature and history in editing the *Bonner Zeitung*. On the outbreak of the revolution of 1848 he took the field, but when Rastatt surrendered he escaped to Zürich. In 1850 he returned secretly to Germany, rescued Kinkel from prison and helped him to escape to Scotland. Schurz went to Paris, but the police forced him to leave France on the eve of the *coup d'état*, and until Aug. 1852 he lived in London, making his living by teaching German. He married in July 1852 and removed to America, living for a time in Philadelphia.

In 1856 after a year in Europe he settled in Watertown, Wisconsin, and immediately became prominent in the Republican Party. In the Illinois campaign of the next year between Abraham Lincoln and Stephen A. Douglas he took part as a speaker; and later in 1858 he began to practise law in Milwaukee. In the State campaign of 1859 he made a speech attacking the Fugitive Slave Law and in the same year he delivered in Faneuil Hall, Boston, an oration on "true Americanism," which coming from an alien was intended to clear the Republican Party of the charge of "nativism." In the Republican national convention of 1860 Schurz was chairman of the delegation from Wisconsin. Lincoln sent him in 1861 as minister to Spain. He returned to America in Jan. 1862, was commissioned brigadier-general of volunteers in April, and in June took command of a division under Frémont, and then in Sigel's corps, with which he took part in the second battle of Bull Run. He was promoted major-general of volunteers on March 14, and was a division commander at Chancellorsville of the XI. Corps, under Gen. O. O. Howard. He was at Gettysburg and at Chattanooga and was then put in command of a corps of instruction at Nashville; he was with Sherman's army in North Carolina in the last months of the war and resigned immediately after the close of hostilities. In 1865 President Johnson sent him through the South to study conditions; but Schurz's valuable report, suggesting the readmission of the States with complete rights and the investigation of the need of further legislation by a Congressional committee, was not heeded by the president. In 1866–67 he was chief editor of the Detroit *Post* and then became editor and joint proprietor with Emil Praetorius (1827–1905) of the *Westliche Post* of St. Louis.

In 1869–75 he was U.S. senator from Missouri, and made a great reputation by his speeches on financial subjects. During this period he broke with the administration: he started the Liberal Republican movement in Missouri in 1870 and in 1872 he presided over the Liberal Republican convention. He opposed Grant's Santo Domingo policy, his Southern policy, and the Government's selling arms and making cartridges for the French army in the Franco-Prussian War. But in 1875 he campaigned for Hayes, as the representative of "sound money," in the Ohio gubernatorial campaign. In 1876 he supported Hayes in the contest for the presidency, and Hayes made him in 1877 his secretary of the interior. Upon his retirement in 1881 he removed to New York city, and from 1881 to 1883 was editor-in-chief and one of the proprietors of the New York *Evening Post*. In 1884 he was a leader in the Independent (or Mugwump) movement against the nomination of James G. Blaine for the presidency and for the election of Grover Cleveland. In 1892 he succeeded George William Curtis as president of the National Civil Service Reform League and held this office until 1901. He succeeded Curtis as editorial writer for *Harper's Weekly* in 1892–98, in which he did much for civil service reform and for Cleveland's nomination and election in 1892. He opposed W. J. Bryan for the presidency in 1896, speaking for sound money; in 1900 on the anti-imperialism issue he supported Bryan. He died in New York city on May 14, 1906.

Schurz published a volume of *Speeches* (1885); *Henry Clay* (1887) in the "American Statesmen" series; *Abraham Lincoln* (1889); and *Reminiscences* (1907–08), in the third volume of which is a sketch of his life and public services from 1869 to 1906 by Frederic Bancroft and William A. Dunning.

SCHUSTER, SIR ARTHUR (1851–), British physicist, was born in Frankfurt-on-Main on Sept. 12, 1851, the second son of F. J. Schuster, a native of Frankfurt, who became a merchant banker in London and a British subject. Arthur Schuster was educated at Owens college, Manchester, and at Heidelberg university, and studied astronomy and mathematical physics. He was chief of the "Eclipse" expedition to Siam in 1875, and from 1888 to 1907 was professor of physics in Manchester university, his main work being connected with advanced research in spectroscopy. He was one of the secretaries of the Royal Society from 1912 to 1920, foreign secretary from 1920 to 1924, and president of the British Association in 1915. He was also secretary of the International Research council, and during the World War he did invaluable work as a scientific adviser for the organization of research in various departments. He was knighted in 1920 and was appointed a member of the royal commission on the universities of Oxford and Cambridge.

His numerous publications include: *Theory of Optics* (2nd ed., 1909); *The Progress of Physics* (1911); *Britain's Heritage of Science* (with Sir A. E. Shipley, 1917); and many papers in philosophical journals.

SCHUSTER, SIR FELIX, Bart. (1854–), British financier, was born on April 21, 1854. He was the third son of F. J. Schuster, and brother of Sir Arthur Schuster (*q.v.*). Felix Schuster was educated at Owens college, Manchester, and studied abroad, afterwards making his career in London banking. From 1895 he was identified, as governor, with the Union Bank of London, afterwards the Union of London and Smiths Bank, and in 1918 amalgamated with the National Provincial Bank as the National Provincial and Union Bank of England. He was a member of the Council of India from 1906 to 1916, and became chairman of the Central Association of Bankers, and of the committee of London clearing banks. In these years he established for himself a leading position in financial and economic circles, and was made a member of several important Government committees and royal commissions. He was created a baronet in 1906.

SCHUYLER, PHILIP JOHN (1733–1804), American soldier, was born at Albany, N.Y., on Nov. 11, 1733. The Schuyler family was established in the New World by Philip Pieterse Schuyler (d. 1683), who migrated from Amsterdam in 1650, and whose son, Peter (1657–1724), was the first mayor of Albany. The family was one of the wealthiest and most influential in the colony and was closely related by marriage to the Van Rensselaers, Van Cortlandts and other representatives of the old Dutch aristocracy. Philip Schuyler served in the Provincial army during the Seven Years' War, first as captain and later as major, taking part in the battles of Lake George (1755), Oswego River (1756), Ticonderoga (1758) and Fort Frontenac (1758). From 1768 to 1775 he represented Albany in the New York assembly, and he was closely associated with the Livingston family in the leadership of the Presbyterian or Whig Party. He was a delegate to the second Continental Congress in May, 1775, and on June 19, was chosen one of the four major generals in the Continental service. Placed in command of the northern department of New York, he made preparations for an invasion of Canada. Soon after the expedition started he was prostrated by rheumatic gout, and the

actual command devolved upon Gen. Richard Montgomery. On the death of Montgomery and the failure to take Quebec the army retreated to Crown Point, and its commander, Gen. John Sullivan, was superseded by Gen. Horatio Gates. Gates claimed precedence over Schuyler and, on failing to secure recognition, intrigued to bring about Schuyler's dismissal. The necessary withdrawal of the army from Crown Point in 1776 and the evacuation of Ticonderoga in 1777 were magnified by Schuyler's enemies into a retrograde movement, and, on Aug. 19, 1777, he was superseded. A court martial appointed in 1778 acquitted him on every charge. He resigned from the army in April, 1779. In 1788 he joined his son-in-law Alexander Hamilton, John Jay and others in leading the movement for the ratification by New York of the Federal constitution. He served in the United States Senate as a Federalist in 1790–91 and was again elected in 1797. He was also active for many years as Indian commissioner and surveyor-general and helped to settle the New York boundary disputes with Massachusetts and Pennsylvania. In 1792–96 he carried to a successful conclusion a project for connecting the Hudson with Lake Ontario by way of the Mohawk, Oneida lake and the Onondaga river. He died on Nov. 18, 1804.

See Bayard Tuckerman, *Life of General Philip Schuyler* (1903).

SCHWAB, CHARLES MICHAEL (1862–), American steel manufacturer and financier, was born at Williamsburg, Pa., on Feb. 18, 1862. He was educated in the public schools and at St. Francis college, Loretto, Pennsylvania. From 1878 to 1880 he was a clerk in a store at Braddock, Pa., and then became a stake-driver in the engineering corps of the Edgar Thomson Steel Works of Carnegie Brothers and Company. His ability brought him rapid promotion and in 1881 he was made chief engineer and assistant manager, and in 1889 general superintendent. In 1892, after the formation of the Carnegie Steel Company, he became general superintendent of the Homestead works. In 1897 he was elected president of the Carnegie Steel Company, and when this was merged in 1901 in the United States Steel Corporation he was its president. In 1903 he resigned from the United States Steel Corporation and soon after obtained control of the Bethlehem Steel Corporation.

After the outbreak of the World War in 1914, and before the United States entered it, these companies filled orders for the Allies aggregating between $400,000,000 and $500,000,000. After America's entrance into the war, Schwab became, in April 1918, director-general of the Emergency Fleet Corporation. After the signing of the Armistice in Nov. 1918, he resigned and returned to his position as chairman of the board of directors of the Bethlehem Steel Corporation. He was president in 1927 of the American Society of Mechanical Engineers and also of the American Iron and Steel Institute.

SCHWABE, RANDOLPH (1885–), distinguished English draughtsman, was born in Manchester on May 19, 1885. He studied at the Slade school and under J. T. Laurens in Paris. During the World War he was official artist to the Ministry of Information. He is a member of the New English Art club and of the London group, and instructor of drawing at the Royal College of Art; examiner in art on the Board of Education. Though essentially modern in spirit, his art adheres to the sound and constructive traditions of the 15th century Renaissance. His illustrations for books are distinguished for clearness of form and delicacy and directness of line. (*See* his designs for the works of Edmund Blunden, Walter de la Mare, Arthur Symons, Elroy Fletcher and John Clare.) Schwabe is also a well known theatrical designer, and has published a valuable book on *Historic Costume* in collaboration with F. M. Kelly (1928). The Imperial War museum has some of his paintings and drawings, the British museum has his prints, etchings and lithographs; the Victoria and Albert museum his designs. He is also represented in the permanent collections at Bradford, Manchester and Oldham. A selection of his drawings appeared in *Contemporary Draughtsmen* (Benn, 1928).

SCHWANN, THEODOR (1810–1882), German physiologist, was born at Neuss in Rhenish Prussia on Dec. 7, 1810. After studying at Cologne, Bonn and Würzburg, he graduated in medicine at Berlin in 1834. There he assisted James Müller in his experimental work on physiology. Schwann in 1838 was called to the chair of anatomy at the Roman Catholic university of Louvain, and in 1847 went as professor to Liège, where he remained till his death on Jan. 11, 1882. While working with Müller, Schwann's attention was directed to the physico-chemical basis of life. In 1836 he demonstrated the influence of organisms and lower fungi in the production of fermentation and putrefaction, and thereby disproved spontaneous generation. In fact the whole germ theory of Pasteur, as well as its antiseptic applications by Lister, is traceable to his influence. About the same time he demonstrated the organic nature of yeast, and the necessity to digestion of the presence of a ferment called by him pepsin.

In 1837 he began to investigate the laws of muscular contraction, discovering the striped muscle in the upper part of the oesophagus, and, later, the envelope of the nerve-fibres which now bears his name. The publication of his famous *Microscopic Investigations on the Accordance in the Structure and Growth of Plants and Animals* in 1839 (trans. Sydenham Society, 1847) set forth his important discovery that both animal and vegetable tissues are to be traced back to cells and that the cells of each are identical in character. His cell theory was taken up by Virchow, who disproved his hypothesis of the discontinuity of cell formation.

SCHWANTHALER, LUDWIG MICHAEL (1802–1848), German sculptor, was born in Munich on Aug. 26, 1802. He studied in Munich and in Italy. After 1832 he found abundant work in Munich, among the new palaces, and museums built by Ludwig I. The palace at Munich is peopled with Schwanthaler's statues, among which are twelve imposing gilt bronze figures, 10 ft. high in the throne-room. He also furnished the old Pinakothek with 25 marbles, commemorative of painters, and supplied a composition for the pediment of the exhibition building facing the Glyptothek. His work in the Ruhmeshalle included ninety-two metopes, and the colossal but feeble figure of Bavaria, 60 ft. high. Outside Munich he executed groups within the north pediment of the Walhalla, Ratisbon, and also numerous portrait statues, including those of Mozart, Jean Paul Richter, Goethe and Shakespeare. Schwanthaler died at Munich in 1848, and left by will to the Munich academy all his models and studies, which now form the Schwanthaler Museum.

SCHWARTZE, TERESA (1852–), Dutch portrait painter, was born at Amsterdam, the daughter of Johan Georg Schwartze (1814–1874). Her portraits are remarkable for excellent character drawing, breadth and vigour of handling and rich quality of pigment. Some of her best pictures, notably a portrait of Piet J. Joubert, and "Three Inmates of the Orphanage at Amsterdam," are at the Ryks Museum, and one entitled "The Orphan" at the Boyman Museum in Rotterdam.

SCHWARZ, KARL (1812–1885), German Protestant theologian, was born at Wiek on the Isle of Rügen on Nov. 19, 1812. Karl Schwarz pursued the study of theology and philosophy at Halle, and afterwards at Bonn (1831) and Berlin (1832–1834). At Berlin he came under the influence of Schleiermacher and Hegel, whose influences are seen in his work *Das Wesen der Religion* (1847). In 1837 he was imprisoned for six months on account of his advanced political opinions. After his release he helped (from 1838) with the *Hallische Jahrbücher*. From 1843–1845 he lectured at Halle, and was then suspended by the government. In 1849, however, he was appointed professor extraordinarius, and later received a number of distinctions (in 1858 chief court preacher, etc.). Schwarz took an important part in the founding and directing of the German Protestantenverein, and became an eminent exponent of liberal theology. His work *Zur Geschichte der neuesten Theologie* (1856, 4th ed. 1869) is a valuable source for the history of theology in Germany. His other works include *Lessing als Theologe* (1854) and *Grundriss der christl. Lehre* (1873, 5th ed. 1876). He died on March 25, 1885.

See G. Rudlöff, *Karl Schwarz* (1887); F. Hummel, *Die Bedeutung der Schrift von Karl Schwarz: Über das Wesen der Religion* (1890).

SCHWARZENBERG, FELIX, Prince zu (1800–1852), Austrian statesman, was born on Oct. 2, 1800.

After six years' service in the Austrian army, Felix espoused a diplomatic career at the instance of Metternich, and underwent

a period of probation (1824–1848) at various European courts, which confirmed his aristocratic aversion to popular government. In 1848 he took an active part in the war against Piedmont and the insurgents in Vienna. On Nov. 21 of the same year he was appointed head of a reactionary ministry, at the instance of his brother-in-law, Prince Windischgrätz. Himself a soldier, he aimed at the ultimate restoration of the absolute monarchy by means of the army. He supervised the abdication of Ferdinand and proclamation of Francis Joseph as Emperor, and although at first he held out prospects of constitutional government, he dissolved the Kremsier Reichstag at the earliest opportunity (March 7, 1849) and late in November called in the Russians to end the war in Hungary. He then turned his attention to Germany. His refusal to incorporate only the German provinces of the monarchy in the proposed new German Empire had thrown the German parliament into the arms of Prussia. His object now was to restore the *status quo ante* of the Confederation, with the old predominance of Austria. His success in this respect was partly due to exterior circumstances, notably the mistimed exaggerations of the German revolutionists, but largely to his diplomatic skill, unscrupulousness and iron tenacity of purpose with which the weakness of Frederick William IV. and his ministers was unable to cope. His triumph came with the restoration of the old federal diet in May 1850 and the signature of the convention of Olmütz on Nov. 29 of the same year. (*See* GERMANY: *History.*) Schwarzenberg was also mainly responsible for Francis Joseph's suspension of the last remnants of the Constitution on Dec. 31, 1851. He died on April 5, 1852.

See Berger, *Felix, Fürst zu Schwarzenberg* (Leipzig, 1853); A. Beer, *Fürst Schwarzenberg's Deutsche Politik bis zu den Dresdener Konferenzen* (Historisches Taschenbuch, Leipzig, 1891).

SCHWARZENBERG, KARL PHILIPP, PRINCE ZU (1771–1820), Austrian field marshal, was born on April 15, 1771, at Vienna. He entered the imperial cavalry in 1788, fought in 1789 under Lacy and Loudon against the Turks, distinguished himself by his bravery, and became major in 1792. At Cateau Cambresis in 1794 his brilliant charge at the head of his regiment, vigorously supported by 12 British squadrons, earned him the cross of the Maria Theresa order. After taking part in the battles of Amberg and Würzburg in 1796 he was promoted major-general, and in 1799 lieutenant field marshal. At Hohenlinden in 1800 his promptitude and courage saved the right wing of the Austrian army from destruction, and he afterwards commanded the rearguard. In 1805 he commanded a division under Mack, and when Ulm was surrounded by Napoleon in October he was one of the brave band of cavalry, under the archduke Ferdinand, which cut its way through the hostile lines. In the same year he was made a commander of the order of Maria Theresa and in 1809 he received the Golden Fleece.

In 1808 he was sent on a mission to St. Petersburg (Leningrad) but returned in time to take part in the battle of Wagram, and was soon afterwards promoted general of cavalry. After the Peace of Vienna he was sent to Paris to negotiate the marriage between Napoleon and the archduchess Maria Louisa. The prince gave a ball in honour of the bride on July 1, 1810, which ended in the tragic death of many of the guests, including his own sister-in-law, in a fire. Napoleon held Schwarzenberg in great esteem, and it was at his request that the prince took command of the Austrian auxiliary corps in the Russian campaign of 1812. In 1813 Schwarzenberg, recently promoted field marshal, was appointed commander-in-chief of the allied Grand Army of Bohemia against France. As such he was the senior of the allied generals who conducted the campaign of 1813–14 to the final victory before Paris and the overthrow of Napoleon. He has been accused of timidity and over-caution but he was always hampered by political considerations: his victory, however achieved, was as complete as Austria desired. His many rewards included the position of president of the Hofkriegsrath, and, as a specially remarkable honour, the right to bear the arms of Austria as an escutcheon of pretence. In 1820, when revisiting the battle-field of Leipzig, he was attacked by a stroke, and died there on Oct. 15.

See Prokesch-Osten, *Denkwürdigkeiten aus dem Leben des Feldmarschall's Fürsten Schwarzenberg* (Vienna, 1823); Berger, *Das Fürstenhaus Schwarzenberg* (Vienna, 1866).

SCHWARZENBERG, a town of Germany, in the republic of Saxony, situated on the Schwarzwasser, 16 m. W. from Annaberg by rail. Pop. (1925) 11,465. It has an old palace. It manufactures paper, tin wares, machinery, worsted, and porcelain, and there are large iron-works in the vicinity.

SCHWECHAT, a small market town in Lower Austria, near the confluence of the River Schwechat with the Danube. Situated in a fertile loess land and only 5 m. from Vienna it is a prosperous town participating in the industrial life of the capital through its huge Dreher brewery, smelting and iron works, cotton-spinning and factories of electrical plant.

SCHWEIDNITZ, a town in the Prussian province of Silesia, situated on the left bank of the Weistritz, 28 m. S.W. of Breslau by rail. Pop. (1925) 30,626. Schweidnitz, dating from about the 11th century, received civic rights in 1250. About 1278 it became the capital of a principality, with an area of about 1,000 sq.m., which belonged to Bohemia from 1353 till 1741, when it passed into the possession of Prussia. The "Pölerei of Schweidnitz" is the name given to the riotous revolt of the town, in 1520–1522, against a royal edict depriving it of the right of coining its own money. The town contains several old churches, one of which was built in the 14th century, and an old town hall. The surrounding country is fertile and highly cultivated, and the large quantities of flax and hemp there raised encourage an active weaving industry in the town. Beetroot for sugar, grain and fruit are also grown. The manufacture of linens, hosiery, furniture, gloves, machinery, margarine, organs, carriages and other hardware goods is carried on. The beer of Schweidnitz has long been famous. Schweidnitz is the chief grain market of the district.

SCHWEINFURT, a town in the republic of Bavaria, on the Main, 27 m. N.E. of Würzburg by rail, and at the junction of lines to Kissingen, Bamberg and Gemünden. Pop. (1925) 36,336. Schweinfurt is mentioned in 790, and in the 10th century was the seat of a margrave. Receiving civic rights in the 13th century, it maintained its independence as a free imperial city with few interruptions until 1803, when it passed to Bavaria. In the Thirty Years' War it was occupied by Gustavus Adolphus, who erected fortifications, remains of which are extant. The Renaissance town hall dates from 1570. St. John's church is Gothic with a tower; St. Salvator's was built about 1720. The chief manufacture is paint, introduced in 1809; but beer, sugar, machinery, ball bearings, bicycles, brushes, soap and other drysalteries, basket work and vinegar are also produced. Schweinfurt is the seat of an important sheep and cattle market.

SCHWEINFURTH, GEORG AUGUST (1836–1925), German traveller in East Central Africa and ethnologist, was born at Riga on Dec. 29, 1836. He was educated at the universities of Heidelberg, Munich and Berlin (1856–62), where he particularly devoted himself to botany and palaeontology. Commissioned to arrange the collections brought from the Sudan by Freiherr von Barnim and Dr. Hartmann, his attention was directed to that region; and in 1863 he travelled round the shores of the Red Sea, repeatedly traversed the district between that sea and the Nile, passed on to Khartoum, and returned to Europe in 1866. In 1868 the Humboldt-Stiftung of Berlin sent him on a scientific mission to the interior of East Africa. Starting from Khartoum in Jan. 1869, he went up the White Nile to Bahr-el-Ghazal, and then, with a party of ivory dealers, through the regions inhabited by the Diur (Dyoor), Dinka, Bongo and Niam-Niam; crossing the Nile watershed he entered the country of the Mangbettu (Monbuttu) and discovered the river Welle (March 19, 1870) which by its westward flow he knew was independent of the Nile. Schweinfurth formed the conclusion that it belonged to the Chad system, and it was several years before its connection with the Congo was demonstrated.

The discovery of the Welle was Schweinfurth's greatest geographical achievement; he also elucidated the hydrography of the Bahr-el-Ghazal system. He described in detail the cannibalistic practices of the Mangbettu, and his discovery of the pygmy Akka settled conclusively the question as to the existence of dwarf

races in tropical Africa. Unfortunately nearly all his collections made up to that date were destroyed by a fire in his camp in Dec. 1870. He returned to Khartoum in July 1871 and published an account of the expedition, under the title of *Im Herzen von Afrika* (Leipzig, 1874, rev. ed. 1918; Eng. ed., *The Heart of Africa,* 1873, new ed. 1878). In 1873–74 he accompanied Gerhard Rohlfs in his expedition into the Libyan desert. Settling at Cairo in 1875, he devoted himself to African studies, historical and ethnographical. In 1876 he penetrated into the Arabian desert with Paul Güssfeldt, and continued his explorations therein at intervals until 1888, and during the same period made geological and botanical investigations in the Fayum, in the valley of the Nile, etc. In 1889 he removed to Berlin; but he visited the Italian colony of Eritrea in 1891, 1892 and 1894. Schweinfurth died in Berlin on Sept. 20, 1925. His botanical and geological collections were given to the Prussian State.

The accounts of all his travels and researches have appeared either in book or pamphlet form or in periodicals, such as *Petermanns Mitteilungen,* the *Zeitschrift für Erdkunde,* etc. Among his works may be mentioned *Artes Africanae; Illustrations and Descriptions of Productions of the Industrial Arts of Central African Tribes* (1875).

SCHWEITZER, JEAN BAPTISTA VON (1833–1875), German politician and dramatic poet, was born at Frankfort-on-the-Main on July 12, 1833, of an old aristocratic Catholic family. He was attracted by the Social Democratic labour movement, and after the death of Ferdinand Lassalle in 1864, he became president of the "General Working-men's Union of Germany," and in this capacity edited the *Sozialdemokrat,* which brought him into frequent trouble with the Prussian Government. In 1867 he was elected to the parliament of the North German Federation, and on his failure to secure election to the German Reichstag in 1871, he resigned the presidency of the labour union, and retired from political life. Schweitzer composed a number of dramas and comedies; also a political novel, *Lucinde oder Kapital und Arbeit* (Frankfort, 1864).

SCHWENKFELD, KASPAR (1490–1561), of Ossing, German theologian, entered the service of the duke of Liegnitz, over whom he had great influence. In 1522 he visited Wittenberg, where he made the acquaintance of Andreas Carlstadt and Thomas Münzer. On his return to Liegnitz he helped to spread the principles of the Reformation in the principality and in Silesia, while warning his colleagues against the abuse of the doctrine of justification by faith. The controversy on the Eucharist (1524) revealed his disagreement with Luther on that critical point. He sought to establish a *via media* between the doctrines of Luther and Zwingli, and vainly hoped to obtain for it Luther's acceptance. He as vainly sought to secure Luther's adoption of a strict rule of church discipline, after the manner of the Moravian Brethren. Meanwhile the Anabaptists obtained a footing in Silesia, and suspicions of Schwenkfeld's sympathy with them were aroused. Letters and writings of his own (1527–1528) proved him to hold strongly anti-Lutheran views, and both Catholics and Lutherans urged the duke of Liegnitz to dismiss him. He voluntarily left Liegnitz in 1529, and lived at Strasbourg for five years amongst the Reformed clergy there. In 1533, in an important synod, he defended against Martin Bucer the principles of religious freedom as well as his own doctrine and life. But the heads of the church carried the day, and Schwenkfeld left Strasbourg for a time. The publication (1539) of a book in proof of his most characteristic doctrine—the deification of the humanity of Christ—led to active persecution by the Lutherans and his expulsion from the city of Ulm. The next year (1540) he published a refutation of the attacks upon his doctrine with a more elaborate exposition of it, under the title *Grosse Confession.* The book emphasized the differences between the Lutherans and Zwinglians on the doctrine of the Eucharist at a moment when efforts were being made to reconcile them. An anathema was accordingly issued from Schmalkald against Schwenkfeld (together with Sebastian Franck); his books were placed on the Protestant "index"; and he himself was made a religious outlaw. Schwenkfeld went into hiding. He and his followers withdrew from the Lutheran Church, declined its sacraments, and formed small societies of kindred views. He died at Ulm, on Dec. 10. 1561.

Schwenkfeld left behind him a sect (who were called subsequently by others Schwenkfeldians, but who called themselves "Confessors of the Glory of Christ") and numerous writings to perpetuate his ideas. His writings were partially collected in four folio volumes, the first of which was published in the year 1564, containing his principal theological works. His adherents were to be found at his death scattered throughout Germany. In Silesia they formed a distinct sect, which persisted. In the 17th century they were associated with the followers of Jacob Böhme, and were undisturbed until 1708, when an inquiry was made as to their doctrines. In 1720 a commission of Jesuits was despatched to Silesia to convert them by force. Most of them fled from Silesia into Saxony, and thence to Holland, England and North America. Frederick the Great of Prussia, when he seized Silesia, extended his protection to those who remained in that province. Those who had fled to Philadelphia in Pennsylvania (1734) formed a small community under the name of Schwenkfelders; and Zinzendorf and Spangenberg, when they visited the United States, endeavoured, but with little success, to convert them to their views. This community still exists in Pennsylvania and their views appear to be substantially those of the Quakers.

Schwenkfeld distinguished between an outward word of God and an inward, the former being the Scriptures and perishable, the latter the divine spirit and eternal. In his Christology he departed from the Lutheran and Zwinglian doctrine of the two natures by insisting on what he called the *Vergötterung des Fleisches Christi,* the deification or the glorification of the flesh of Christ. His peculiar Christology was based upon profound theological and anthropological ideas, which contain the germs of some recent theological and Christological speculations.

Theol.* (1867); also R. H. Grützmacher's article in Hauck-Herzog's *Realencyklopädie;* Robert Barclay's *Inner Life of the Religious Societies of the Commonwealth* (1876); C. Beard's *Hibbert Lectures* (1883); H. W. Kriebel, "The Schwenkfelders in Pennsylvania," *Pa.-German Soc. and Addresses,* vol. xiii. (1904); and S. K. Brecht, *The Geneological Record of the Schwenkfelder Families* (1923).

SCHWERIN, KURT CHRISTOPH, Count von (1684–1757), Prussian general field marshal, was born at Löwitz, Pomerania. He served in the Dutch army and then in the Mecklenburg-Schwerin armies during the War of the Spanish Succession. In 1713 he was with Charles XII. of Sweden in his captivity at Bender, and in 1718 was made major-general. In 1719 he opposed the Hanoverian army which invaded Mecklenburg (in the course of which he fought a brilliant action at Walsmühlen on March 6, 1719), and in 1720 entered the Prussian service. In 1730, as a major-general, he was a member of the court-martial which tried the crown prince of Prussia (afterwards Frederick the Great) for desertion, and in 1733, at the head of a Prussian army, conducted with great skill the delicate and difficult task of settling the Mecklenburg question. Frederick promoted Schwerin to the rank of general field marshal and made him a count. At the battle of Mollwitz (April 10, 1741) his brilliant leading converted a doubtful battle into a victory. In the Second Silesian War (1744–1745) Schwerin commanded the army which, marching from Glatz, met the king's army under the walls of Prague and contributed to the capture of that place. In the first campaign of the Seven Years' War (1756) he conducted the war on the Silesian side of Bohemia; and in 1757, following the same route as in 1744, again joined Frederick at Prague. On May 6, leading on a regiment of the left wing to the attack with its colour in his hand, the old field marshal was shot dead.

See Varnhagen von Ense, *Biographische Denkmale,* vol. vi. (3rd ed., Leipzig, 1873), and *Leben Schwerins* (Berlin, 1841).

SCHWERIN, a town of Germany, the capital of the republic of Mecklenburg-Schwerin, situated at the south-west corner of the lake of Schwerin 129 m. by rail N.W. of Berlin, and 20 m. S. of the Baltic. Pop. (1925) 46,905. Schwerin is mentioned as a Wendish stronghold in 1018, its name (*Zwarin* or *Swarin*) being a Slavonic word signifying "game-preserve." The town, founded

in 1161 by Henry the Lion in opposition to this pagan fortress, received civic rights in 1166. From 1170 to 1624 it gave name to a bishopric; and it was also the capital of the duchy of Schwerin, which formed the western part of the grand-duchy of Mecklenburg-Schwerin. Destructive fires, the hardships of the Thirty Years' War, and the removal of the court to Ludwigslust in 1756 seriously depressed the town.

The town is closely surrounded and hemmed in by a number of lakelets. Though Schwerin is the oldest town in Mecklenburg, its aspect is comparatively modern, a fact due to destructive fires, which have swept away most of the ancient houses. The most conspicuous of the many fine buildings is the former ducal palace built in 1844–57 in the French Renaissance style. It stands on a small round island between Castle lake and the lake of Schwerin, formerly the site of a Wendish fortress and of a later mediaeval castle. The older palace, the government buildings and the museum all stand in the "old garden," an open space at the end of the bridge leading to the new palace. Among the other secular buildings are the former palace of the heir-apparent, and the library. The cathedral was originally consecrated in 1248, though the present building—a brick structure in the Baltic Gothic style, with an unfinished tower—dates for the most part from the 15th century. The chief industry is the making of furniture, and there are also some manufactures of dyes, pianos, wool yarn, sugar, cement and soap.

SCHWERTE, a town in the Prussian province of Westphalia, 9 m. N. E. of Hagen by rail, at the junction of the lines Aix-la-Chapelle-Holzminden and Schwerte-Münster. Pop. (1925) 16,326. Schwerte received civic rights in the 12th century. It has a Romanesque church, with a carved altar of 1523, and stained glass of the 14th and 15th centuries; and there is a 16th century town hall. The industries are practically confined to the manufacture of iron and steel goods.

SCHWIEBUS, a town in the Prussian province of Brandenburg, 47 m. E. of Frankfort-on-Oder by the railway to Posen. Pop. (1925) 9,734. The territory of Schwiebus originally belonged to the principality of Glogau, and in the 16th and 17th centuries was a bone of contention between the electors of Brandenburg and the emperors. In 1686 the elector received the lordship of Schwiebus on renouncing his claims to certain other principalities. Frederick III., however, restored Schwiebus to the emperor Leopold I. in 1695, receiving £40,000 in exchange. By the peace of 1742, Frederick the Great regained Schwiebus with the rest of Silesia. The town is still in part surrounded by its mediaeval wall, and has an old market-place, a castle and many old houses. Cloth, machinery, and bricks are manufactured, and there are flour-mills, breweries, and lignite mines.

SCHWIND, MORITZ VON (1804–1871), German painter, was born in Vienna in 1804. His early art training was rudimentary and at 17 he entered the circle of artists who gathered around Schubert in the capital and became a devoted friend and admirer of the composer, dividing his enthusiasm between music, poetry and painting. In after life he frequently introduced Schubert's portrait or the subjects of his songs into his paintings and illustrations. In 1827 Schwind went to Munich, where he came under the influence of Schnorr and Cornelius, and in 1834 was commissioned to decorate Ludwig II.'s new palace with wall-paintings after Tieck. The revival of art in Germany was favourable to the development of his fanciful genius and he soon became popular through his illustrations of Goethe and other poets. From 1844 he lived in Frankfort, where he painted the "Singers' Contest in the Wartburg" (1846), made the designs for the Goethe celebrations and did numerous book illustrations. In 1847 he became professor at the Munich academy. He died at Munich in 1871.

Schwind also designed the wall-paintings for the castle of Hohen-Schwangau in the Bavarian Tirol and for the Wartburg. In 1857 he published a cycle of the *Seven Ravens* from Grimm. Many of his watercolours etc. of the early Vienna days are preserved in the City Museum, and the Schubert sketches, including the large portrait group, "Schubert-Abend bei Josef R. von Spaun," a sepia drawing completed about 1868, are in the Schubert Museum, Vienna. His "Symphony" (Neue Pinakotek, Munich) also contains portraits of Schubert and others of the circle.

See Karl Kobald, *Schubert und Schwind* (1928).

SCHWOB, MARCEL (1867–1905), French author. Many of his novels have an historical setting, but his art is extraordinarily versatile, and includes tales of imagination, of the future, legends, psychological essays, and many short stories. In the prefaces to *Coeur double, Roi au masque d'or* (1893) Schwob makes an attempt to analyse his art. In spite of his unusual historical, linguistic and scientific knowledge, and his crowded canvas, his style is simple and straightforward. His work includes translations of Shakespeare and Defoe. He had a wide and close knowledge of English literature. He was a friend of Oscar Wilde, who dedicated *Salome* to him. The *Vies Imaginaires* (1896, reprint 1922) is a series of sketches in which the *légendes* of various famous people are the basis, rather than their actual lives.

His works include *Spicilège* (1896); *La Croisade des Enfants* (1896); *La Lampe de Psyché* (1903); *La Guerre Commerciale* (2 vols. 1896 and 1904).

SCHWYZ, one of the ancient forest cantons of central Switzerland. Its total area (1923–24 determinations) is 350·5 sq.m., of which 78·7% are reckoned as "productive" (forests covering 72·4 sq.m. and vineyards about 30 ac.) while of the rest 18·1 sq.m. are occupied by the larger lakes (chiefly several square miles of Zürich and of Lucerne, together with a small area of Zug and the whole of Lowerz—1·2 sq.m. draining into Lucerne); about 0·5 sq.m. is covered by glaciers. Its loftiest point is the Böser Faulen (9,199 ft.), while the two highest summits of the Rigi (the Kulm, 5,742 ft., and the Scheidegg, 5,463 ft.) are within its borders, but, on the whole, the land is hilly rather than mountainous. Its title as the "core of Helvetia" is more appropriate in respect of its position, for though much below average size for a Swiss canton, no less than seven other cantons touch its borders. It has two main valleys, the Muota receiving the waters of Lake Lowerz and draining into Lucerne, and the Sihl, which receives the river Alp on which Einsiedeln stands; the reinforced stream, though formed near the head of the Lake of Zürich, flows for a long distance roughly parallel to it and enters the river Limmat below the lake. The canton has but few main line railways, the principal being a portion of the main St. Gothard line between Sisikon and Küssnacht. Arth-Goldau (memorable for the great landslide of 1806) is a railway junction of some importance, with a line to Zug and another past Biberbrücke (junction for Einsiedeln and the water falls) towards Wädenswil. A popular mountain-railway also terminates at Arth-Goldau for the ascent of the Rigi-Kulm, with a branch to Rigi-Scheidegg. Of other mountain lines in the canton the most important is the electric cogwheel railway from Brunnen to Axenstein.

In 1920 the population was 59,731, of whom 58,337 were German-speaking, 912 Italian-speaking and 279 French-speaking, showing during the 20th century a substantial increase of the German tongue and a reduction in the other elements. There were 56,669 Catholics, 2,924 Protestants and 25 Jews. Schwyz, until 1814 in the diocese of Constance, now forms part of the see of Choire. The largest town is Einsiedeln (pop. 8,228), a great pilgrimage centre noted for its black Virgin and its Benedictine monastery. Schwyz (pop. 8,139), is the political capital and is connected with Brunnen, its port on Lucerne. The canton is essentially a pastoral one, its local race of brown cattle being much esteemed, particularly in north Italy, but some industrial activity (textiles) also takes place near the Lake of Zürich and the home weaving of silk is still general. The 30 cantonal communes are grouped into six administrative districts. The Constitution, dating mainly from 1876, was revised in 1898. The legislature (*Kantonsrat*) is composed of 103 members elected in the proportion of one for every 600 residents, and the elections, since 1907, take place according to the principles of proportional representation. The executive (*Regierungsrat*) of seven members is elected by a popular vote and, as is the case with the larger

body, holds office for four years. The two members of the federal *Ständerat* and the three of the federal *Nationalrat* are also chosen by a popular vote. Since 1876 the "obligatory referendum" has prevailed in the case of all laws and financial resolutions approved by the legislature, while 2,000 electors may claim a popular vote as to any remaining decrees or resolutions. Any 2,000 electors have also the right of "initiative" as to the revision of the cantonal Constitution or as to legislative matters.

History.—The valley of Schwyz is first mentioned in 972 as "Suittes." Later, a community of freemen settled at the foot of the Mythen, subject only to the count of the Zurichgau, as representing the German king. In 1240 the community obtained from the emperor, Frederick II., the privilege of being subject immediately to the empire. Its territory then included only the district round the village of Schwyz and the valley of the Muota. But in 1269 it bought from Count Eberhard, of Habsburg-Laufenburg, Steinen and Rothenthurm. Schwyz took the lead in making the famous everlasting league of Aug. 1, 1291, with the neighbouring districts of Uri and of Unterwalden, its position and political independence specially fitting it for this prominence. An attack by Schwyz on Einsiedeln was the excuse for the Austrian invasion that was gloriously beaten back in the battle of Morgarten (Nov. 15, 1315). In the history of the league Schwyz was always to the front, so that its name in a dialectal form (Schweiz) was from the early 14th century onwards applied by foreigners to the league as a whole, though it formed part of its formal style only from 1803 onwards. After the victory of Sempach (1386) Schwyz greatly extended its borders. An "alliance" with Einsiedeln in 1397 ended in 1434 with the assumption of the position of "protector" of that great monastery; between 1386 and 1436 the whole of the "March" (the region near the upper lake of Zürich) was acquired; in 1402 Küssnacht was bought, and in 1440 the "Höfe," the parishes of Wollerau, Feusisberg, and Freienbach, situated on the main lake of Zürich. All these districts were governed by Schwyz as "subject lands," the supreme power resting with the *Landsgemeinde* (or assembly of all male citizens of full age). Schwyz joined the other forest cantons in opposing the Reformation, and took part in the battle of Kappel (1531), in which Zwingli fell. In 1798 Schwyz, including Gersau (free from 1390), formed part of the République Telliane (or Tellgau), set up by the French, which a week later gave way to the Helvetic republic. In 1803 the separate canton of Schwyz was again set up. Schwyz joined, in 1832, the league of Sarnen, and in 1845 the Sonderbund, which was put down by a short war in 1847. In 1832 the outer districts (Einsiedeln, the March, Küssnacht, and Pfäffikon) formed themselves into a separate canton, an act which brought about a federal occupation of the old canton in 1833, this ending in the dissolution of the new canton, the constituent parts of which were put on an equal political footing with the rest. In 1838 strife broke out in the older portion of the canton between the richer peasant proprietors (nicknamed the "Horns," as they owned so many cows) and the poorer men (dubbed the "Hoofs," as they possessed only goats and sheep) as to the use of the common pastures, which the "Horn" party utilized far more than the others. The "Horn" party finally carried the day at the Landsgemeinde held at Rothenthurm. The cantonal constitution of 1848 put an end to the ancient Landsgemeinde; it was revised in 1876 (when membership of one of the 29 communes became the political qualification), and in 1898.

SCHWYZ, the capital of the Swiss canton of that name, a picturesque little town, admirably situated, amid fruit trees, on a mountain terrace (at a height of 1,706 ft.), at the north-west foot of the conical peak of the Gross Mythen (6,240 ft.). Including the neighbouring hamlets of Ibach, Rickenbach, etc., the parish had 8,139 inhabitants in 1920, practically all German-speaking and Roman Catholics. The town is about 3 m. from Brunnen, its port on the lake of Lucerne.

Besides a stately 18th century parish church and several convents, it contains a 16th century town hall (housing various precious mss.), as well as several curious old patrician houses.

SCIACCA (Arabic, *Sciaqqak*), a town and episcopal see of Sicily, on the south coast, in the province of Girgenti, 52 m. N.W. of Girgenti by rail, and about 30 m. direct. Pop. (1921) 20,052 (town); 25,630 (commune). It is surrounded by walls erected about 1550, and has two ruined castles, belonging to the Luna and Perollo families, whose hereditary feuds lasted from 1410 to 1529, some fine medieval and 18th century palaces, and several interesting churches. The convent of Sta. Maria delle Giummare, with its battlemented walls, occupies the former palace of the Saracen governors, and contains a painting of the foundation of the convent by Count Roger. The town has only an open roadstead. Three miles E. of the town is the Monte San Calogero (the ancient Mons Cronius) with sulphurous and saline springs and vapour baths, which are still used and were known in Roman times as Aquae Larodes or Thermae Selinuntiae (Sciacca is about 15 m. direct S.E. of Selinus). The town is the birthplace of Tommaso Fazello (1498–1570), the father of Sicilian history.

See I. Scaturro, *Storia della città di Sciacca* (1925–26).

SCIALOJA, VITTORIO (1856–), Italian jurist and statesman, son of the eminent Neapolitan scientist, patriot and statesman, Antonio Scialoja, was born at Turin, and after graduating in jurisprudence was appointed professor of civil law at the University of Camerino when only 23 years of age. In 1880 he was transferred to the University of Siena, and in 1884 to that of Rome, where he still teaches. Many of the most distinguished jurists and political men in Italy have been his pupils, and through his teachings and writings he has exercised a wide influence on juridical thought and practical legislation. In 1904 he was nominated senator, and since then he has played an active part in Italian political life. In 1909 he was appointed minister of justice, and during the World War he was minister (without portfolio) in the Boselli and Orlando cabinets. In the autumn of 1919, on the resignation of Senator Tittoni, Senator Scialoja became minister of foreign affairs in the Nitti cabinet, and in this capacity he attended various meetings of the Peace Conference, either as assistant Italian delegate under Sig. Nitti or as first delegate. He left office on the fall of the cabinet in June 1920, and in the autumn of that year became a member of the Italian delegation at the League of Nations Assembly. Since 1925 he has been president of the Italian delegation at the Assembly and Italian representative on the Council of the League, in whose activities he has played an important part since its birth, having indeed collaborated in the drafting of the Covenant.

He is the author of a large number of books, pamphlets and articles on legal subjects, of which the most important are the following: *Sopra il precarium nel diritto romano* (1878); *Degli atti di emulazione nell' esercizio dei diritti* (1878); *Del diritto positivo e dell' equità* (1880); *Responsabilità e volontà nei negozi giuridici* (1885); Italian translation, with an introduction, of Savigny's *System of Roman Law* (8 vols., 1886–98); *Sul diritto al nome e allo stemma* (1889); *Sulla teoria dell' interpretazione della legge* (1898); *Dizionario pratico del diritto privato* (1899, etc.); *Sulle condizioni impossibili nei testamenti* (1901); *Sulle funzioni della IV. Sezione del Consiglio di Stato* (1901).

SCIATICA, a form of neuralgia localized in the sciatic nerve, or its cords of origin; *see* Neuralgia: *Paralysis*.

SCIENCE, a word which, in its broadest sense, is synonymous with learning and knowledge. (Lat *scientia,* from *scire,* to learn, know.) Accordingly it can be used in connection with any qualifying adjective, which shows what branch of learning is meant. But in general usage a more restricted meaning has been adopted, which differentiates "science" from other branches of accurate knowledge. For our purpose, science may be defined as ordered knowledge of natural phenomena and of the relations between them; thus it is a short term for "natural science," and as such is used here in conformity with a general modern convention.

The Origin of Science.—The beginnings of physical science

are to be sought in the slow and unconscious observation by primitive races of men of natural occurrences, such as the apparent movements of the heavenly bodies, and in the gradually acquired mastery over the rude implements by the aid of which such men strove to increase the security and comfort of their lives. Biological science similarly must have begun with observation of the plants and animals useful to man, and with empirical medicine and surgery. Again, it is probable that magic, by which man tries to obtain direct control over nature, helped to lead both to primitive religion and also, directly or indirectly, to practical science. But it was only when considerable progress had been made with ordered knowledge that men began to seek natural causes for phenomena, and to discern the connections between them.

In the earliest stage of development it seems that an anthropomorphic or mythological explanation is always assigned to the phenomena of nature. With no clue to trace the regularity of sequence and connection between those phenomena, an untutored mind inevitably refers the apparently capricious events which succeed each other to the direct and immediate intervention of some unseen being of a nature essentially similar to his own. The sun is the flaming chariot of the sun-god, driven day by day across the heavens; the clouds are cows from which milk descends as nourishing rain on the fruitful earth. We may regard such myths as childlike fancies, but they were doubtless an advance on the lack of explanation which preceded them; they supplied hypotheses which, besides providing suggestive themes of beauty for poetry and art, played the first and chief part of a scientific hypothesis in pointing the way for further inquiry. Much useful knowledge was acquired and much skill gained in logical analysis before these primitive explanations were proved insufficient. A false theory which can be compared with facts may be more useful at a given stage of development than a true one which is beyond the comprehension of the time, and is incapable of examination by any known means of observation or experiment.

The phenomena of the heavens are at once the most striking, the most easily observed and the most regular of those which are impressed inevitably on the minds of thinking men. Thus it is to astronomy we must look for the first development of scientific ideas.

Early Astronomy.—The orientation of many prehistoric monuments shows that a certain amount of astronomical observation had been acquired at a very early age, and the Chaldeans seem to have gone so far as to recognize a law of periodicity even in eclipses. The earliest known systematic advance on the mythological view of nature is to be found in the writings of the Ionian philosophers of whom Thales of Miletus (580 B.C.) is regarded as the first. Anaximander recognized the rotation of the heavens round the pole star, and saw that the dome overhead was but the half of a complete sphere. The earth was thus deprived of the base stretching to unfathomed depths imagined by the mythologists, and was left free to float as a flattened cylinder at the centre of the celestial sphere.

Next came the Pythagoreans, who simplified these conceptions by the suggestion that instead of a rotation of the vast sphere of the heavens the earth itself might be a sphere and revolve about a central fixed point, like a stone at the end of a string. The uninhabited side of the earth always faced the fixed point, and its inhabited side faced successively the different parts of the heavens. At the central fixed point they placed a "universal fire," which, like the fire on an altar, served as a centre for the circling of the worshipping earth. Mythology was losing its hold of science, but mystical symbolism still held sway. When, however, in the 4th century B.C., the growth of geographical discovery failed to disclose any trace of this central fire, the idea of its existence faded away, and was replaced by the conception of the revolution of the earth on its own axis. At a later date, Aristarchus (280 B.C.), believing that the sun was larger than the earth, thought it unlikely that it should revolve round the earth, and developed a heliocentric theory. But the time was not ripe; no indisputable evidence could be adduced, no general conviction followed, and to mankind the earth remained the centre of creation for many centuries. Even to Lucretius, the visible universe consisted of the central earth with its attendant water, air and aether surrounded by the sphere of the heavens, which formed the flaming walls of the world—*flammantia moenia mundi.*

The Problem of Matter and the Theory of Atoms.—Simultaneously with the birth of astronomy, the problem of matter came into being. The old Ionian nature philosophers, observing the sequence of changes from earth and water into the structure of plants and the bodies of animals, and through them again into the original constituents, began to grasp the conception of the indestructibility of matter, and to put forward the idea that all forms of matter might ultimately consist of a single "element." But the conception of a single ultimate basis of matter was far in advance of the age. It has only lately become a fertile working hypothesis in the light of all the gigantic increase in knowledge gained during the intervening two thousand years. At the time when it was put forward, the conception was of little use, and the immediate path of advance was found in the idea of Empedocles (450 B.C.) that the primary elements were four: earth, water, air and fire—a solid, a liquid, a gas and the flame which seemed to the ancients a type of matter of still rarer structure. This hypothesis served to interpret the phenomena of nature for many centuries, till, in modern days, the growth of chemistry disclosed the ninety and more elements of our text-books. And now they too have served their turn as a conception of the ultimate nature of matter, while still maintaining their place as the proximate units of chemical action.

In the four elements of Empedocles we trace the germ of the ideas of the Atomists. Empedocles saw that, by combining his separate elements in different proportions, he could explain all the endless differences in matter as known to the senses. Leucippus and Democritus developed the conception and gave to the world the theory of atoms, described at a later date by the Roman poet Lucretius. As matter is subdivided does it keep its characteristic properties throughout? Is iron always iron, however finely we divide it; is water always water? Are the properties of any kind of matter ultimate facts of which no explanation—no description in simpler terms—is possible? To avoid answering this last question in the affirmative, and resigning all hope of an advance in knowledge, the atomic theory of the Greeks was framed.

To recognize the significance of the doctrines of the Greek Atomists, we must remove from our minds all sense of comparison with the atomic theory of to-day. The Greeks had none of the detailed physical and chemical knowledge on which that theory is founded, and which it was framed to explain. The object of Leucippus and Democritus was quite different from that of Dalton and Avogadro. To the latter, the conception of atoms and molecules served as a means of explaining certain definite and detailed facts of chemical combination and gaseous volume in a more definite and exact way than any other hypothesis available at the time. To the Greek philosophers, the atomic theory was an attempt to make the universe intelligible. The particular explanation offered was not of so much importance as the idea that an explanation of some kind was possible. When we see the beliefs that held sway before their day, we realize the advance their ideas produced. The qualities of substances were thought to be of their essence—the sweetness of sugar was as much a reality as sugar itself, the black colour of water must survive all changes in its form, so that, to one who knew this doctrine, snow could never look white again. It was such confusion as this—such denial of facts if they failed to support a theory—that Democritus assailed:—"According to convention there is a sweet and a bitter, a hot and a cold, and according to convention there is colour. In truth there are atoms and a void." Atoms were many in size and shape, but identical in substance. All qualitative differences in substances were to be assigned to differences in size, shape, situation and movement of particles of the same ultimate nature. No attempt was made to examine into the nature of this ultimate substance; but one set of phenomena was expressed in terms of something simpler, and that is the essence of "explanation."

But the great difference between the position of the Greeks and that of ourselves in regard to natural knowledge consists in the

small number of phenomena known to them contrasted with the enormous wealth of accumulated observation which is available for us, as the result of centuries of experiment with the aid of apparatus unknown to the ancients. When a new theory is put forward, it is now almost always possible to test its concordance with facts by the use of material already accumulated, or to suggest, in the light of such material, experiments which will serve to refute it, or to lend it greater probability. Thus a theory which survives the trials that follow its birth has nowadays a fairly long expectation of life—probably the theory will serve to interpret phenomena discovered either by its means or in other ways for some time to come. But in the ancient world this was not so. To test a new theory, other phenomena were very rarely available than those which suggested it, or to explain which it was put forward. Thus thought was much more speculative, and, as is still the case with metaphysics, no general consensus of opinion was reached. Each philosopher had a system of his own in science, just as he still has in metaphysics—a system which, beginning anew from first principles, raises on them a superstructure, which, even if it logically follows from them, can have no more validity than the premises on which it is based. Thus to the Greeks, natural knowledge was truly philosophy. Philosophy can formulate natural problems and suggest different possible answers: when the time has come, science takes over the subject and decides between them.

The history of the atomic theory of Leucippus and Democritus illustrates the difficulties of a position where speculation has outstripped observation. The theory was nearer what is now accepted as truth than any other of the ancient schemes of physics. Yet the grounds on which it was based were so insecure that Aristotle (*c.* 340 B.C.), who started with other preconceptions, was able to bring to bear such destructive criticism that the theory ceased to occupy the foremost place in Greek thought. Democritus, for instance, had held that all things would fall with equal speed in a vacuum, and that the fact that heavy bodies were observed to fall faster than very light ones was due to the resistance of the air. Democritus's belief was true, though he was of course quite unconscious of the grounds on which it can alone be explained—the universal acceleration of gravity, and the remarkable and curious experimental fact that the weights of bodies are proportional to their masses. Aristotle agrees that in a vacuum all bodies would fall at an equal rate, but the conclusion appears to him so inconceivable that he rejects the idea of the existence of any empty space at all, and with the "void" rejects the rest of the allied concepts of the atomic theory. If all bodies were composed of the same ultimate matter, he argues, they must all be heavy, and nothing would be light in itself and disposed to rise. A large mass of air or fire would then necessarily be heavier than a small mass of earth or water. This result he thinks impossible, for certain bodies always tend upwards and rise faster as their bulk increases. It will be seen that Aristotle has no idea of the conceptions we now call density and specific gravity, though clear views about the question why some things rise through water or air might have been obtained without the aid of physical apparatus. Aristotle's doctrine that bodies are essentially heavy or light in themselves persisted all through the middle ages, and did much to delay the attainment of more exact knowledge. It was not till Galileo Galilei (1564–1642) discovered by actual experiment that, in cases where the resistance of the air is negligible, heavy things fall at the same speed as light ones, that the Aristotelian dogma was overthrown.

Early Biology.—Turning to the biological sciences, we may trace a somewhat similar course of development. Owing to its practical importance, medicine has left many records by which its progress can be traced. Just as primitive man personified the sun and the moon, the wind and the sea, so he regarded disease as due to the action of some malignant demon or to the spells of some human enemy. Greek literature enables us to trace the gradual decrease in the importance assigned to charms and magic, and the growth of more rational ideas among Greek physicians. But here, as in the physical sciences, the philosophic range of the intellect of the Greeks led them astray. Assumptions as to the nature of man or the origin of organic life were too often made the starting point of a train of deductive reasoning, the consequences of which were not always compared with the results of observation and experiment, even where such comparison was possible.

Among the multitude of their guesses, a few somewhat resembled the views that are now again rising into prominence from the basis of definite and exact experiment. A good example of the strength and weakness of ancient speculation is found in the cosmogony of the atomists, both on its physical and on its biological side. Lucretius describes how the world was formed by the conjunction of streams of atoms, which condensed into the earth, with its attendant water, air and aether, to form a self-contained whole. Unconscious of the mighty gap between inorganic matter and living beings, he proceeds to tell how, in the chances of infinite time, all possible forms of life appeared, while only those fittest to survive persisted and reared offspring. Here, surrounded by unsupported statements and false conclusions, we see dimly the germs of the ideas of the nebular hypothesis and the theory of natural selection, though Lucretius had the profoundest ignorance of the difficulties of the problem, and the vast stretches of time necessary for cosmical and biological development.

In those branches of biological science in which less ambitious theorizing and more detailed observation were forced on the Greeks, considerable progress was made. Aristotle compiled a laborious account of the animals known in his day, with many accurate details of their anatomical structure. Beginning from an earlier date, steady advance was made with geographical discovery. Maps of the known world, developed from the local maps invented by the Egyptians for the purposes of land-surveying, gave definiteness to the knowledge thus acquired, and showed its bearing on wider problems.

Geometry.—One of the most striking successes of Greek thought is seen in the development of geometry, the best type of deductive reasoning. Geometry has a twofold importance, as being itself the study of the properties of the space known to our senses, and as teaching us methods and means of studying nature by unfolding the full logical consequences of any hypothesis. Based on axioms, the result of innate ideas according to one school or of simple experience according to another, it traces from the ideas of solids, surfaces, lines and points the properties of other figures defined in terms of those ideas. As an example to other sciences, the deductive geometry of Euclid (*c.* 300 B.C.) had, perhaps, an unfortunate influence in emphasizing the deductive method, and teaching men to neglect the need of verifying by experiment the theories put forward to explain the more complex phenomena of nature at the conclusion, and at each possible step, of the deduction. But, in itself, the science of Euclidian geometry was brought to such a state of perfection that no advance was made till modern times: no change even in form attempted till quite recently. Unlike some other branches of inquiry we have mentioned, Euclid's geometry carried universal conviction, and represented a permanent step in advance which never had to be retraced.

Besides studying individual sciences, the Greeks paid even more attention to the laws of thought, and to the examination of the essence of the methods by which knowledge in general is acquired. In opposition to Plato's theory that all knowledge is but the unfolding and development of forgotten memories of a previous state of existence, Aristotle taught that we learn to reach the generalizations, which alone the Greeks regarded as knowledge, by remembering, comparing and co-ordinating numerous particular acts or judgments of sense, which are thus used as a means of gaining knowledge by the action of the innate and infallible *nous* or intellect. Neither Plato nor Aristotle could be satisfied without finding infallibility somewhere. Aristotle, it is true, investigated the logical processes by which we pass from particular instances to general propositions, and laid stress on the importance of observing the facts before generalizing about them, but he had little appreciation of the conditions in which observation and the induction based on it must be conducted in practice in order to obtain results where the probability of error is a minimum. Aristotle regarded induction merely as a necessary preliminary

to true science of the deductive type best seen in geometry, and, in applying his principles, he never reached the "positive" stage, in which metaphysical problems are evaded, if not excluded, and a scheme of natural knowledge built up in a consistent manner, so that metaphysical ideas, though they may underlie the foundation of the ultimate conceptions, do not intrude between the parts of the building. Hence Aristotle's explanations often turn directly on metaphysical ideas such as form, cause, substance, terms which do not occur (in the Aristotelian sense) in modern scientific terminology.

The Origin of Mechanics.—A century later than the time of Aristotle, Archimedes of Syracuse (287 to 212 B.C.) formulated the fundamental conceptions of hydrostatics, and took what may be regarded as the first step in the exact science of mechanics. The use of the lever must have been discovered at a very early date, and Archimedes set to work to study its quantitative laws. He made use of axioms which seemed to him to be simpler, and applied thereto deductive principles learnt from the geometers. Nowadays we should treat the law of the lever of unequal arms as one that is verified by direct and familiar experiment, and use it, in its turn, as the starting point for further deduction. Nevertheless, Archimedes' proof is of use and interest, a true type of all scientific "explanations." It reduces an unfamiliar phenomenon to others already well known to our minds, which, being creatures of habit, regard the familiar cases as in no need of explanation.

The Dark Ages and Mediaeval Period.—Thus before the intellectual activity of Greece was absorbed by the utilitarianism of Rome, which, in its turn, was lost in the dark ages following the barbarian conquests, the seeds were sown which, germinating after the lapse of centuries, developed in the more fruitful soil of the age of experiment. The ancient knowledge only survived fragmentarily in compendiums written just before the dark ages. Thereafter, secular learning, based on those compendiums, settled down into the elementary "trivium," consisting of grammar, rhetoric and dialectic, and the more advanced "quadrivium," music, arithmetic, geometry and astronomy. Music included a half-mystical doctrine of numbers and the rules of plainsong; geometry consisted of a selection of the propositions of Euclid without the demonstrations; while arithmetic and astronomy were cultivated chiefly because they taught the means of finding Easter. Meanwhile, the early alchemists of Alexandria, by the aid of mystical analogies with the conceptions of astrology, were making primitive experiments on the transformations of various substances. It was probably from them that the "sacred science" passed to the Arabs, among whom the greatest was one Jabir, who (*c.* A.D. 750) discovered many new chemical reactions and compounds.

With the intellectual revival in the west which began in the 11th century, and the gradual recovery of some of the lost works of the ancient writers, we turn a new page. The controversy between Plato and Aristotle upon the doctrine of ideas fascinated the minds of the middle ages, saturated as they were with the logical subtleties of dialectic. This controversy originated the long debate on the reality of universals, which absorbed the intellectual energies of many generations of men. Did reality belong only to the idea or universal—to the class rather than to the individual—to the common humanity of mankind, for instance, rather than to each isolated being? Or were the individuals the reality, and the universals mere names or mental concepts? In this question, trivial as it seems at first sight, logical analysis disclosed to the mediaeval mind the whole theory of the universe. Either answer contained danger to theological orthodoxy as then understood; hence the fervour with which it was debated. But, as communication with the East was reopened early in the 13th century, Latin translations of Aristotle's works were recovered gradually; the whole of Aristotle's philosophy was reimported into the schools of Europe, and reconciled with and adapted to Christian theology chiefly by the work of Saint Thomas Aquinas. A complete rational synthesis of knowledge was thus put together, in which Religion, Philosophy and Science formed inter-connected parts of the whole. In virtue of this synthesis, for three hundred years Aristotle reigned supreme in European thought, and exponents of the scholastic philosophy, ignoring their master's teaching on the need of experiment, settled questions of fact as well as those of opinion by an appeal to his books. Nevertheless, the subtlety of the schoolmen kept alive intellectual interests in Europe, and thus prepared the way for science. Outside the newly founded universities, experiment was carried on by the labours of the alchemists, who, early in the 13th century, borrowed ideas from the Arabs, and began to search for an *elixir vitae* and for a means of transmuting baser metals into gold. But alchemy never quite squared its account with orthodox theology, and the "sacred science" of the Alexandrians became associated in the mediaeval mind with the "black art" of witchcraft. Even a man like Roger Bacon, who, with some astrological mysticism, had a more modern idea of experiment both in chemical and physical problems, did not escape condemnation.

The Renaissance.—We now reach the period in the history of the world known as the Renaissance, when increased material prosperity and improved political stability in the 15th and 16th centuries gave many converging streams of thought opportunity to unite. The Renaissance was not, as it is sometimes represented, a sudden break with mediaevalism and a birth of the modern world. A number of conditions favourable to rapid development happened to coincide, and, in the course of a century, men's outlook on themselves and on nature became profoundly modified. The recovery of the Greek language, the voyages of Columbus, the decay of the Western and the passing of the Eastern empire, the temporary diminution in power of the papacy, the invention of printing, all tended to produce new ideas and to prepare men's minds to accept the more human and naturalistic view of the universe which had been current among the Greeks, in place of the theological aspect which it wore to the mediaeval schoolmen and ecclesiastics. At first the tendency was to substitute the authority of the ancients for the authority of the schoolmen, but gradually more independence of thought was secured; men like *Leonardo da Vinci* (1452–1519) began to observe and to experiment; *Nicolaus Copernicus* (1473–1543) revived the heliocentric theory, and showed how the accumulated mass of astronomical observations could be interpreted by its means; and *Vesalius* (1514–1564) took up again the study of anatomy, which gradually made its way in the schools of medicine, in face of the prejudice against mutilating the human body.

Physics.—In physics the true method was first used freely by Galileo Galilei (1564–1642), who, turning the newly invented telescope to examine the stars and planets, increased enormously the evidence for the theory of Copernicus. But a greater achievement was the foundation of the science of dynamics. We have seen how the Aristotelians held the belief that every body sought its natural place, the place of heavy bodies being below and that of light ones above. Innate qualities of heaviness and lightness were thus invoked, and it was believed that heavy things always fell faster than light ones. Galileo, rightly rejecting the current point of view, set himself to examine not why, but how, things fell. First he showed that, save for a small error due to the resistance of the air, heavy and light bodies fall at the same rate. Next, by trying the consequences of one hypothesis after another till he found one that was both self-consistent and gave deductions in accordance with experiment, he proved that the space traversed by a falling body is proportional to the square of the time of fall. To verify this result experimentally, Galileo convinced himself that a body falling down an inclined plane acquired a speed which is the same as that it would have attained in falling through the same vertical height. He could therefore use a slow movement down a plane for his experiments instead of the unmanageably rapid course of a body falling freely. Nor was this all. From this stage of the investigation another consequence of his results was found to spring. A ball after running down an inclined plane of a certain height will run up another plane of the same height irrespective of its inclination—that is, if friction be small. The second plane may be made very long, but still, if its final height be not greater than that of the first, the ball will reach its end. Hence it is the height that matters; none of the speed of the ball is destroyed unless it rises. If the second plane be made horizontal, the

ball will thus run on for ever unless stopped by friction or some other applied force. This fundamental result, put into definite words by Newton, is known as the first law of motion, and is the foundation of the whole science of dynamics. In Galileo's day it was an entirely new conception. It had been assumed that every motion required some cause or force to maintain it. Hence arose the need of hypothetical vortices to maintain planetary movements, and similar complications in other branches of mechanics. But it now became evident that it was not the continuous motion of the planets which needed explanation, but the constant deflection of that motion from the straight path it would hold if no applied force were in action. The way was open for Newton.

Sir Isaac Newton (1642–1727) proved mathematically that the observed motion of the planets about the sun could be explained by the supposition that the sun exerted a force on each planet proportional inversely to the square of its distance from the planet. But the earth, at any rate, does seem to attract bodies on or near its surface, the phenomenon being the familiar but mysterious gravity. Is this force competent to account for the motion of the moon round the earth? On the assumption of the law of inverse squares, Newton calculated what the force of gravity would be at the distance of the moon and got a fair concordance with facts. But he put aside his calculations till, some years later, he proved mathematically that a sphere would attract other bodies as though all its mass were collected at its centre. He could then treat the problem accurately and thus found that the fall of a stone to the earth and the sweep of the moon in her orbit were due to the same cause. The mechanism by means of which the force is exerted remained unrevealed to Newton, and baffled all inquirers till Einstein showed that this problem was soluble by quite other means. But Newton's discovery that all the movements of the heavens could be described by one simple law was the first great physical synthesis, and perhaps represents the highest achievement in the history of science.

A position similar to that won for physics by Galileo and Newton was only reached in chemistry a century later. Then Lavoisier, by the test of the balance, showed that the total mass involved remained unchanged throughout a chemical reaction, and, by his re-discovery of oxygen, explained combustion as the combination of ordinary substances possessing mass and weight.

Newton brought the existing state of the solar system within the cognizance of known dynamical principles, and the logical extension of such principles to explain the origin of that system was made by the speculations of *Pierre Simon, marquis de Laplace* (1749–1827), and developed by those who followed him down to Sir James Jeans in our own day. They have imagined a primitive state of nebulosity from which, by the action of known dynamical processes, the stellar universe and our sun and planets would be evolved.

The discovery by Sir George G. Stokes (1819–1903), J. B. L. Foucault (1819–1868), R. W. Bunsen (1811–1898) and G. R. Kirchhoff (1824–1887), that the spectroscope gave a means of investigating the chemical composition of the sun and the stars, brought another set of phenomena within the range of experiment, while the differences observed in stellar spectra suggested once more the idea of cosmical development, familiar from the nebular hypothesis of Laplace.

Geology.—Similar principles were during the 19th century applied to the history of the earth. The earlier conceptions of the origin of the rocks imagined catastrophes of fire or water, processes alien to those of everyday experience. But the "uniformitarian" school, founded by James Hutton (1726–1797) and expounded by Sir Charles Lyell (1797–1875), produced evidence to show that much, at any rate, of the structure of the surface of the globe was produced by processes still going on under our eyes. The deposition of material by the action of seas, rivers and volcanoes, was seen to need only time enough to produce beds of rock like those which make up our mountains. Comparison of the fossil remains of plants and animals found in different strata then enabled geologists to classify the rocks, and place them in a chronological sequence. Moreover, it became evident that a series of animal and plant types was associated with the gradual formation of the rocks, and that the age both of the earth itself and of the organic life found on it was much greater than had been suspected. The few thousand years of received cosmogonies stretched out into untold millions, during which the same familiar laws described the phenomena of development. The remains and traces of man, found, it is true, only in the later sedimentary deposits of the earth, were enough to prove his existence through ages beside which the dawn of history was but as yesterday. As Newton had extended known principles throughout the gigantic spaces of the heavens, so the later astronomers and geologists pushed them back over enormous epochs of time.

Physiology and Biology.—Turning back to the 17th century, we find William Harvey starting physiology on its true course by his discovery of the circulation of the blood. By experiments on living animals, Harvey (1578–1657), von Haller (1708–1777), Bernard (1813–1878) and many others, investigated the mechanism of circulation, respiration, digestion and the other functions of the body, and thus made modern medicine and surgery possible. Moreover, they showed that physical and chemical principles are applicable in physiology, and gave new support to the idea of "man as a machine," which, whether or no it be a complete explanation, is an almost necessary assumption for physiological research.

The part played by micro-organisms in disease, made clear by Pasteur (1822–1895) and his disciples, the multitudinous life of tropic lands observed during voyages of scientific exploration, the revelations of geology—all combined with the new knowledge of physiology to prepare the way for the biological work of Charles Darwin (1809–1882). The origin of living beings from a few ancestral types was an old conception, but Darwin first found an adequate intelligible cause in the slow action of sexual selection, in conjunction with the pressure of the struggle for life, which allowed only those individuals most suited to the environment by favourable variation to survive and rear their offspring. The advantage thus given to beings with useful variations may develop into permanent modifications in the course of ages, and, when the parent types have disappeared, their common posterity may exhibit the marked differences characteristic of the separate and distinct species now existent. From the point of view of the history of science, the significance of Darwin's theory lies in the new and vast extension it gives to the field in which causes intelligible to the human mind can be sought as explanations of phenomena. Thus evolution is co-ordinated in the history of thought with the Newtonian theory of gravitation, with physical and chemical theories of physiology and with the uniformitarian theory of geology.

Both before and after the appearance of Darwin's work, biologists devoted their attention to the study of how useful variations arise. Three views have been held. (1) Jean Baptiste, chevalier de Lamarck (1744–1829), regarded variation as due to the accumulated and inherited effect of use. Thus the giraffe acquires his long neck by the successive efforts of countless generations to browse on leaves just beyond their reach. (2) Darwin, while accepting changes in accordance with Lamarck's ideas as exceptional aids to variation, revolutionized biology by showing the primary importance of the struggle for life, when extended over long periods of time, in selecting useful variations which arise accidentally or in other ways. (3) Darwin also recognized the possible occasional effect of discontinuous variations or "sports," when a plant or an animal diverges from its parents in a marked manner. But of late years the rediscovery of the forgotten work of G. J. Mendel, Abbot of Brünn (1822–1884), and further study by Hugo de Vries, William Bateson and others, of discontinuous variations which arise spontaneously, have pointed to the conclusion that in nature such sudden leaps are the normal cause of development. If a "sport" has advantages over the parental type, it tends to survive, while, if it is not as fitted for its life struggle, it is destroyed by natural selection and never establishes itself. Such a theory does something to avoid the difficulty of pure "Darwinism," that organs useful, when fully developed, to an animal or plant are of no advantage in incipient stages.

Closely connected with such problems is the question of

inheritance. Lamarck's theory required the inheritance of characteristics acquired during the life of a parent. But difficulties, such as that of seeing how such a change could affect the simple germ cells, have led some more recent biologists to deny the possibility of any acquired characteristic being transmitted to offspring. This question, like that of the sufficiency of Darwinism and Mendelism to explain the facts of evolution, is still the subject of controversy. (*See* HEREDITY.)

Modern Physics.—Simultaneously with the growth of geology, and the birth of the Darwinian hypothesis, a new development took place in physical science—the development of the conception of energy as a quantity invariable in amount throughout a series of physical changes. The genesis of the idea in its modern form may be traced in the work of Newton and C. Huygens (1629–1695), who applied it to the problems of pure dynamics. But, in the middle of the 19th century, by the work of James Prescott Joule (1818–1889), Lord Kelvin (1824–1907), H. L. F. von Helmholtz (1821–1894), J. Willard Gibbs (1839–1903), R. J. E. Clausius (1822–1888) and others, it was extended to physical processes. The amount of heat produced by friction was found to bear a constant proportion to the work expended, and this experimental result led to the conception of an invariable quantity of something, to which the name of energy was given, manifesting itself in various forms such as heat or mechanical work. Energy thus took its place beside mass as a real quantity, conserved throughout a series of physical changes. Of late years, as we shall see below, evidence has appeared to show that mass is not constant, but may depend on the velocity when the velocity approaches that of light, while still more recent work suggests that mass and energy are mutually convertible. Since the only essential quality of matter is its mass, these results seem to strike at the root of the metaphysical conception of matter as a real, invariable quantity.

In ordinary physical conditions, the amount of energy in an isolated system remains invariable, but, if changes are going on in the system, the energy tends continually to become less and less available for the performance of useful work. All heat engines require a difference of temperature—a boiler and refrigerator, or their equivalents. We cannot continue to transform heat into mechanical work if all available objects are at a uniform temperature. But, if temperature differences exist, they tend to equalize themselves by irreversible processes of thermal conduction, and it becomes increasingly difficult to get useful work out of the supplies of heat. In an isolated system, then, equilibrium will be reached when this process of "dissipation of energy" is complete, and, from this single principle, the whole theory of the equilibrium of physical and chemical systems was worked out by Kelvin, Helmholtz and Willard Gibbs. Such a method avoids altogether the use of atomic and molecular conceptions.

But the other great line of advance in recent physics has been traced by a method which uses atomic and molecular conceptions in an extreme form. The passage of electricity through liquids had been explained by Michael Faraday (1791–1867), Kohlrausch and others as a transference of a succession of electric charges carried by moving particles of matter or ions. At the end of the 19th century these ideas were extended, chiefly by the labours of J. J. Thomson, to elucidate also the conduction of electricity through gases. In 1897 Thomson discovered that, in certain cases, the moving particles which carried the electric current were of much smaller mass than the smallest chemical atom, that of hydrogen, and that these minute particles, to which he gave the name of corpuscles, were identical from whatever substance they were obtained. They enter into the structure of all matter, and form a common constituent of all chemical atoms. The only known properties of these corpuscles are their mass and their electric charge. Now, a charged body when set in motion spreads electromagnetic energy into the surrounding medium. Thus, more force is needed to produce a given acceleration than if the body were uncharged. The body acts as though its mass were greater than when it is uncharged. Indeed there is reason to believe that the whole apparent mass of the minute corpuscles to which we have referred is an effect of their electric charge. The idea of a material particle thus disappears with that of material mass, and the corpuscle becomes an isolated unit of electricity—an electron, while electricity, mass and energy become different manifestations of the same underlying condition.

Another train of reasoning, starting from a different point, reinforces this result. The phenomena of the interference of beams of light in certain circumstances to produce darkness or colour, indicate that light is some form of wave motion, and, to carry these waves, a hypothetical luminiferous aether was invented. The theoretical work of J. Clerk Maxwell (1831–1879) and the experiments of H. R. Hertz (1857–1894) showed that the properties and velocity of propagation of light and of electromagnetic waves were identical and that their other properties differed only in degree. Thus light became an electromagnetic phenomenon. But light is started by some form of atomic vibration, and to start an electromagnetic wave requires a moving electric charge. Electric charges must exist within the atom, and we are led again to the theory of electrons by the road opened up by H. A. Lorentz and Joseph Larmor. Such a theory suggests the occasional instability of the atom, and the phenomena of radioactivity, shown in a remarkable form by the substance radium, discovered by M. and Mme. Curie, have been explained satisfactorily by the theory of Rutherford and Soddy, who regard the energy liberated as due to the disintegration of the atom. The evolutionary view of nature, established in the biological and sociological sciences, is thus extended to physical science, not only in the development of planets and suns, but even in the chemical atoms, hitherto believed indestructible and eternal. Many complex radioactive changes have been investigated in detail by Sir Ernest Rutherford and his pupils, and several new elements have been discovered.

Relations between the atomic weights of the elements and their properties were traced by Mendeléeff (1834–1907) and others, but in 1913 and 1914 a new light was thrown on the problem by H. G. J. Moseley. As diffraction gratings, surfaces ruled with multitudes of parallel scratches, give spectra with ordinary light, so the much finer atomic layers of crystals produce spectra when the even more minute waves of X rays are reflected from them. The structure of crystals has been investigated thus by Sir William and W. L. Bragg. Bombarding an element with cathode rays and using a crystal as grating, Moseley obtained X ray spectra, and discovered that the square roots of the frequencies of vibration of the characteristic X rays increase by equal steps as we ascend the list of elements in order of increasing atomic weight. Each element can thus be given an atomic number, ranging from 1 for hydrogen to 92 for uranium, and save for three gaps, elements corresponding to all intervening integral numbers are known. These numbers have an important physical meaning in the modern theory of the atom.

Meanwhile the atomic weights were shown to be whole numbers by the researches of Aston, who, by deflecting positive electric rays in strong magnetic and electric fields, measured accurately the mass of flying atoms. The chief exception is hydrogen, with an atomic weight of 1·008. Helium consists of four hydrogen nuclei, but its atomic weight is exactly 4. Thus, when an atom of helium is built up from hydrogen, there is a destruction of mass and an equivalent liberation of energy.

It proved to be an impossibility to explain either sharp line spectra or the localization of energy in continuous spectra by the vibration of electrons in orbits in accordance with Newton's dynamics. To overcome these difficulties, Planck devised a Quantum Theory, according to which energy is emitted in definite units or quanta. Led chiefly by the facts of radio-activity, Rutherford had come to view an atom as essentially a positive nucleus with negative electrons round it, and this view was adapted to the quantum theory by Bohr. Hydrogen has a nucleus of one positive unit or proton, with one electron circling round it, according to Bohr in one of four definite orbits. By supposing that radiation is emitted only when the electron leaps instantaneously from one stable orbit to another, Bohr explained many of the phenomena of the hydrogen spectrum. More complex atoms are imagined to be made of two or more positive protons bound together by a smaller number of negative electrons in a nucleus, the rest of the

electrons outside the nucleus being more loosely connected. Moseley's atomic number gives the number of these outer electrons.

In 1925 it became apparent that Bohr's theory of electronic orbits failed to explain the finer structure of spectra, and a new "wave mechanics," due chiefly to Heisenberg, de Broglie and Schrödinger, took its place. The electron then took on the likeness of both a particle and a wavelet, with either its position or its velocity mathematically indeterminate. We seem to be getting down to fundamental concepts, which cannot be represented to the mind in the guise of physical models, but must be left in terms of mathematical equations.

To explain the propagation of light, it had been necessary to imagine the existence of an aether to carry the waves. Yet the measured velocity of light proved to be the same in all directions, and therefore independent of the relative motion of the aether. The first comprehensive explanation of this difficulty was given by A. Einstein in 1905. Einstein pointed out that absolute space and time are metaphysical figments of the imagination. Time and space as known to us are determined by an observer, himself moving in certain ways, and may be different if measured by another observer. Thus time and space are relative and not absolute. Moreover they must be so connected that the velocity of light is always constant however measured—the first constant of the new physics. While space and time individually are relative, yet, as pointed out by Minkowski, a certain combination of them is absolute—the same for all observers—one second being equivalent to 180,000 miles, the distance described by light in that time. According to Einstein, in this space-time continuum, bodies move in natural paths, straight in empty space but curved near matter owing to something analogous to curvature in space-time. Thus Newton's idea of gravitational force may be unnecessary. (*See* SPACE-TIME.)

Mathematical investigation showed that this theory of relativity leads to consequences approximately the same as Newton's theory—so nearly the same, indeed, that it has needed all our experimental resources to decide in favour of Einstein. The most famous of the crucial experiments is based on the very minute deflection of a ray of light as it passes near the sun. This is twice as great on Einstein's theory as on Newton's.

The principle of relativity also involves the equivalence of mass and energy already suggested by other lines of research. In recent years the possible conversion of mass into energy has been used by astronomers to explain the old problem of the continued output of radiant heat from the sun and other stars. That output is now believed to be due to subatomic changes at the enormous temperature of many million degrees which must exist inside dense stars radiating heat and light. Some of it may be supplied by the conversion of one element into another, but a far greater store of energy would be liberated by the mutual cancellation of protons and electrons, whereby mass, passing completely into radiation, would be annihilated.

Thus in two directions—the quantum theory and relativity—recent science seems to be breaking away from the fundamental conceptions by which it has been guided since the days of Galileo and Newton. It is too soon as yet to look for a complete and consistent scheme of physics based on these new ideas. They are at present in that fascinating early stage of new knowledge when consistency is hardly a virtue, when indeed it is more useful to follow bravely each fresh line of development than to make premature attempts to co-ordinate the whole.

This historical sketch may help to make clear the method of science, and to throw some light on its value and meaning. Modern science began with the Renaissance. Mediaeval Scholasticism was a complete synthesis of knowledge, deduced rationally from premises regarded as certain—firstly, the doctrines of the Christian Faith as set forth by the Fathers and safeguarded by the Roman Church; secondly, human knowledge as found chiefly in Aristotle and applied by Christian Doctors, especially St. Thomas Aquinas. There was still room for interpretation and exposition, but no need for change, no idea of development. Thus the new experimental method brought about a revolution. The idea of a complete synthesis of knowledge was dropped. The new science was empirical and not rational; it observed and experimented on some quite limited problem; accepted the results whether or no they were in accordance with preconceived ideas; started again on another problem, and sometimes found that the two solutions agreed. It did not deduce knowledge *a priori*, but put it together slowly and laboriously like fitting the pieces into a puzzle.

Scholasticism, based on Revelation and Aristotle, assumed that it was dealing with reality, that the world in essence was what it seemed to be. Modern science, on the other hand, soon learnt that many of the superficial appearances of things—colour, taste or sound—are to it but the effect on the senses of matter in motion. Thus men came to regard matter and motion as real, and only later understood that they too were but useful concepts of the mind—that science itself was dealing with appearance and not necessarily with reality.

The Methods and Meaning of Science.—The philosophy of the new experimental methods was first studied by *Francis Bacon* (1561–1626). Warned by the failure of the scholastic methods to give a true knowledge of nature, Bacon laid exclusive stress on the value of experiment. As a corrective applied to the mediaeval philosophy Bacon's work was of the greatest value in the history of thought, and, from this point of view, it is perhaps but a small drawback that scientific discovery is seldom or never made by the pure Baconian method. The multitude of phenomena are too great for any subject which aims at explanation and not only at description to be attacked with success without the aid of hypothesis framed by the use of the scientific imagination. Facts are collected to prove or disprove the consequences deduced from the hypothesis, and thus the number of facts to be examined becomes manageable. If agreement is found, the hypothesis is, so far, confirmed, and gains in authority with every fresh concordance discovered. If the deductions from the hypothesis do not agree with the accepted interpretation of facts, the hypothesis may need modification, it may have to be abandoned altogether, or the want of concordance may point to some error or inconsistency in the fundamental concepts on which the hypothesis is based—the whole framework of that branch of science may need revision.

Even while Bacon was philosophizing, the true method was being practised by Galileo, who, with a combination of observation, hypothesis, mathematical deduction and confirmatory experiment, founded the science of dynamics. When Kepler had collected astronomical phenomena under a few general laws and Newton had given a mathematical theory which co-ordinated them all, the first great scientific synthesis was accomplished, the first separate pieces of the puzzle put together into a limited but consistent pattern.

The Classification of the Sciences.—In early times, when the knowledge of nature was small, little attempt was made to divide science into parts, and men of science did not specialize. Aristotle was a master of all science known in his day, and wrote treatises alike on physics and on animals. But as it became impossible for any one man to grasp all scientific subjects, lines of division were drawn for convenience of study and of teaching. Besides the broad distinction into physical and biological science, minute subdivisions arose, and, at a certain stage of development, much attention was given to methods of classification, and much emphasis laid on the results, which were thought to have a significance beyond that of the mere convenience of mankind.

But we have reached the stage when the different streams of knowledge, followed by the different sciences, are coalescing, and the artificial barriers raised by calling those sciences by different names are breaking down. Geology uses the methods and data of physics, chemistry and biology; no one can say whether the science of radioactivity is to be classed as chemistry or physics, or whether sociology is properly grouped with biology or economics. Indeed, it is often just where this coalescence of two subjects occurs, when some connecting channel between them is opened suddenly, that the most striking advances in knowledge take place. The accumulated experience of one department of science, and the special methods which have been developed to deal with its prob-

lems, become suddenly available in the domain of another, and many questions insoluble before may find answers in the new light cast upon them. Such considerations show us that science is in truth one, though we may agree to look on it now from one side and now from another as we approach it from the standpoint of physics, physiology or psychology.

The Philosophical Basis of Science.—Having traced the development of the most important of the fundamental conceptions of science, let us now examine the meaning of the knowledge thus acquired, and its relation to other branches of learning.

By the slow and laborious methods of observation, hypothesis, deduction and experimental verification, a scheme has been constructed which for the most part is consistent with itself, and bears the test of the comparison of one part with another. As a chart is drawn by the explorer of unknown seas to represent his discoveries in a conventional manner, so the scientific investigator constructs a mental model of the phenomena he observes, and tests its consistency with itself and its concordance with the results of further experiment. The chart does not give a lifelike picture of the coast as does a painting, but it represents one aspect of it conventionally in a manner best adapted for the immediate purpose. So the conceptions of one branch of science—mechanics, let us say—represent the phenomena of nature in the conventional aspect best suited for one particular line of inquiry. It does not follow necessarily that "nature" in reality resembles the particular mental chart which mechanical science enables us to construct. It does not even follow that there is any "reality" underlying phenomena and corresponding with any of our conceptions. The whole problem which mankind has to face undoubtedly includes an inquiry into the ultimate nature of reality. But that inquiry lies in the province of metaphysics, and is not necessarily involved in the pursuit of natural science. Metaphysics uses the results of natural science, as of all other branches of learning, as evidence bearing on her own deeper and more difficult questions. But it does not follow that natural science must solve metaphysical problems before being of use to man and enlarging the sphere of his knowledge. We need not ask whether the reality is represented accurately by our conventional model before using that model to introduce order into what would otherwise be mental confusion, and to enable us to make systematic and progressive use of natural resources. It is true that the possibility of constructing consistent schemes of scientific concepts is an argument in favour of the existence of a definite reality underlying phenomena resembling in some respects the pictures of it we draw. But metaphysicians are not agreed that it is a conclusive argument.

The difficulty of making a scientific picture of the ultimate nature of reality may be illustrated by an example. Our first conception of a wooden stick involves the ideas of a certain long-shaped form, of smoothness, of hardness, of weight, of a certain brown colour, perhaps of some amount of elasticity. A microscope reveals a structure much more detailed than we imagined, and our mental model of the stick ceases to be smooth. It becomes co-ordinated with those of a number of other bodies which we know to be parts of trees, the growth and structure of which we study by the help of botany. From the results of observation and experiment, physics teaches us that the properties of the stick can only be represented satisfactorily by imagining that the substance of it is not infinitely divisible, that it consists of discontinuous particles or molecules. Again, chemistry assures us that the molecules of the stick are made up of still smaller parts or atoms, which separate from each other when, for instance, the stick is burned, and afterwards can arrange themselves into new molecules. When we pursue our inquiries into the nature of these atoms, we find that they can be resolved, partly at any rate, into much smaller particles or corpuscles in continual motion within the atom. These corpuscles themselves have been identified with isolated units of negative electricity or electrons, the vibrations of which within the atom sort out the electromagnetic radiation which falls on them and allow to reach our eyes those waves only which give us the sensation of brown colour.

At present pioneers are attempting to look beyond the electron into still more intimate details of structure. But we have travelled far from our original conception of the nature of the stick, and, should the problem last stated be solved, we should only find ourselves faced by the next one, the nature of the units at which, for the time being, we have arrived. But what constitutes reality? Where, in the endless chain of explanations discovered or to be discovered, can we stop and say: "Here is the true picture of what the stick *is*"? But this impossibility does not prevent us from getting the full use of each conception in turn when used for its particular purpose. To the schoolboy, the effective and deterrent conception of the stick is that of a hard, elastic, long-shaped solid. The botanist regards it as built up by the action of vegetable cells, which he refers to a particular kind of tree. To the chemist the stick is made up of atoms of carbon, hydrogen and oxygen, each with definite properties and arranged in certain combinations. The physicist sees these atoms composed of whirling electrons, each an ultimate electric unit not yet capable of further explanation. Each idea is useful in turn. Since science is analytic it tends to regard the physical concepts, such as space, time, mass, atom, electron, as the most fundamental. They may or may not correspond with something in ultimate reality: with that science is not concerned. But accepting as convenient these and other less fundamental concepts, science examines experimentally the relations between them, and it is these relations which are the Laws of Nature about which so much has been said. We may not know what realities, if any, underlie the concepts of mass, length or time, of electric current or electro-motive force. But Ohm found that whatever they really be, current is proportional to electro-motive force, and Newton showed that, to a very high order of accuracy, two masses produce a mutual acceleration proportional directly to the product of the masses and inversely to the square of the distance between them. Nowadays we believe that mass, time and space are not what Newton thought, and the exact point of accuracy at which his law fails has been discovered by Einstein. But the law remains as a permanent achievement, all the more useful because its limits of accuracy are known. The gradual piecing together of such natural laws constitutes science, and the ultimate test of its validity can only be the final consistency with each other of the parts of the whole structure.

Such considerations show us the meaning of the subdivisions into which science has been arranged for convenience of study and research. They represent different aspects of nature, different sections, as it were, cut through the solid model which stands for the sum of all our scientific knowledge of the universe. The idea that a mechanical explanation of any known phenomenon is fundamental and complete may be traced to the familiarity of mechanical conceptions in our every day experience. The popular ideas of matter and force are not scientific definitions, but they lead to a false idea that the exact scientific concepts with the same names are understood. Matter is defined scientifically in terms of its mass or inertia, and is commonly known to us by our sense of touch, by its resistance to force. But the fact that we have a muscular sense, which gives us the impression of a force and so of mass and matter, is an accident of our bodies and minds. The electric fish or torpedo may have an electric sense, and a fish-philosopher might argue that it is more intelligible and satisfactory to explain mass in terms of electricity than electricity in terms of mass. Even to us, there seems now no reason to regard mechanics as philosophically the most fundamental science. It is merely one aspect from which we may regard any definite problem.

A nerve-impulse may be regarded from a psychological aspect when we deal with the thought which accompanied it; from a physiological aspect when we examine its relation to other changes in the body. But modern methods have co-ordinated it also with definite chemical and electrical changes, and are said sometimes to have "explained" the nerve-impulse in physical terms. But, as always, an "explanation" proves to be simply a restatement of a phenomenon in terms of ideas which are already familiar to the mind, and therefore appear to be better understood. Nevertheless, from our present point of view, no one of these possible aspects of the phenomenon—of the nerve-impulse—is essentially more fundamental than any other. To the psychologist the nerve-impulse is expressed in terms of thought, to the physicist by physi-

cal changes. The fact that a thought is accompanied by movement of matter or electricity does not make it less fundamental. The two manifestations appear together; there is "psychophysical parallelism." But the question of the connection between them cannot, at present at any rate, be answered by science. Now, and perhaps always, it is a problem for metaphysical speculation.

SCIENTIFIC MANAGEMENT. The science of industrial management began in a machine-shop and was there developed by careful and systematic experiment and observation and guided, controlled and directed by an able, patient and persistent student, Frederick Winslow Taylor (*q.v.*). Writing in 1911, after he had retired from practice, Taylor said "at least 50,000 workmen in the United States are now employed under this (the Taylor) system of scientific management, and they are receiving from 30% to 100% higher wages daily than are paid to men of similar calibre with whom they are surrounded; while the companies employing them are more prosperous than ever before. In these companies the output per man and per machine has, on the average, been doubled. During all these years there has never been a strike among the men working under this system. In place of the suspicious watchfulness, and more or less open warfare which characterize the ordinary types of management there is now free cooperation between the management and the men."

No doubt, most of us when we first hear of such a thing as the science of shovelling by hand, are apt to be amused; shovelling is labour which anybody is supposed to be fitted for if he is sufficiently strong and phlegmatic. So far as is known, no one ever made a systematic study of shovelling, until Taylor, whose personal experience in manual work had been only as a machinist and pattern-maker, undertook to develop the science of shovelling in a large steel plant where many kinds of material were being handled, the heaviest being iron ore, the lightest, small size anthracite coal. Taylor selected a few of the better shovellers whom he placed under the instruction of trained observers; these men worked on various materials, using several sizes of shovels under differing conditions. Careful records were kept of every phase of the work; the effect of rest periods of different lengths and frequency was noted. It was finally determined that the best results were obtained when the shovel load was kept as close as possible to 21 lb., which was much less than the usual load for the heavier materials and much more than for the lighter ones, in other words, shovels had been regularly over-loaded for the heavy iron ore and much under-loaded for the lighter coal. Special shovels were then secured, each designed to hold 21 lbs. of the material for which it was to be used. Teaching and supervision were maintained, and when the new plan was in full operation, the average wages of the shovellers were 63% higher, though the cost of handling had decreased 54%. During the first year the total savings to the works in the cost of shovelling, including all increased overhead, amounted to $36,417.69.

Scientific management has sometimes been confused with the division and specialization of labour, and with mass production—both of which are fundamentally different. Adam Smith (1723–1790) described in his *Wealth of Nations* the division of labour and also mass production (*q.v.*) in the making of pins by hand. This same principle now made use of in the abattoir processes, and in the manufacture of automobiles, is sometimes erroneously called *scientific management*, though it frequently is combined with highly scientific management methods.

Machine Shop Tests.—In 1879, in a department of the Midvale Steel works, Philadelphia, a group of men were operating lathes on heavy work, mostly steel forgings. Taylor, who had been placed in charge of that department, soon became convinced that the men knowingly were not and did not intend doing the work they could easily accomplish. For certain reasons—not all traceable to the men—Taylor could not secure their co-operation in experiments designed to show how much work could be done. Finally, a 66 in. boring- and turning-mill was set aside to be used only for Taylor's experiments. During a period of six months many steel tires for locomotive driving-wheels were reduced to chips at various cutting speeds and feeds, using many different shapes of cutting tools; and, though it was then clear that only a beginning had been made in the development of the science of metal cutting, enough had been learned to more than pay for this pioneer work. Through a period of years many thousands of controlled experiments were made, and more than 800,000 lbs. of steel were cut up. The chemical and physical characteristics of each piece of metal were known, and it was thus revealed that for each variety of material there is, for each lathe, an optimum combination of cutting speed, etc.

During these experiments and tests, conditions were standardized; and this led to a progressive development of the lathe itself and to many investigations which, though only incidental to the main purpose of the work, turned out to be highly important in themselves.

Leather Belting.—One of the by-product investigations is given in Taylor's classic paper on leather belting (*Trans. A.S. of M.E.*) which first gave engineers concrete, comprehensive and definite information as to just what a leather belt may be depended upon to do in power transmission. As a direct outcome of these experiments, lathes were largely re-designed. Cutting tools were given new shapes and standardized; a new tool grinding machine was designed and, finally high-speed steel was invented by Taylor and Maunsel White. The first public exhibition of this new steel attracted much attention by turning forged steel at speeds sufficient to heat the chips to a deep blue. This one result of Taylor's studies has very greatly increased the output per man in most machine shops.

Operations Standardized.—For many kinds of work, however, the cutting speed is not the only important element. The operations of placing and fastening the work in position, and adjusting the cutting tools properly are of equal importance. All such work and many varieties of purely manual operations were studied; and, by separating these operations into their elements and timing each element by means of stop watches, the best combinations were determined and so combined as to make the most efficient complete operation, which was usually not only faster but more easily performed because it was done with the minimum of muscular effort and nervous strain.

Use of Stop Watches.—In determining the best manner of performing a piece of work, many studies were made by men with stop-watches, which must never be used secretly but only with the full co-operation of the worker. The workers are not, however, to be driven to accomplish the operations, but each is carefully and patiently instructed; being assured that, upon attaining a given degree of proficiency, he will be paid a premium, or bonus, the amount of which varies with the character of the work, but is always sufficient to be attractive. Besides higher wages and contented workers, the results are lower labour costs and lower total costs of production, notwithstanding a possible higher ratio or proportion of what is variously called "overhead expense," "operating expense" or "operating cost."

The New Plan of Management.—It became increasingly clear that maximum production could not be obtained until a system of management based upon a new conception of its functions had been devised. Things which had been left to the workers or to overburdened foremen should be attended to by others, preferably trained specialists. Tools and machines must be known to be ready for use when needed and in the best possible condition. Materials must always be on hand in the proper quantities; the successive operations and their proper sequence must be care-

fully planned by experts. Accompanying each shop order there should be full directions for executing it in accordance with the plan and within the predetermined time. A central planning department, in which all work is carefully laid out, is essential—usually expert workmen being trained for this work. Men with proper equipment move materials from one station to the next in accordance with directions; and thus the stream of materials is changed from a large, slow-moving one to a much smaller stream moving steadily and rapidly. Work spaces are much less congested, and often very great savings are made in inventories of raw stock, and of parts "in process," thus freeing capital for some useful purpose. No expenditure need be made upon any job until the way is cleared for it to go through the works without delay, and without interference with or by any other work.

Functional Foremen.—It was early perceived that the workmen could not be expected to go on doing work correctly if left to themselves or to the direction of a too-busy foreman, and so functional foremen were trained who issue directions for the execution of each component part of the work. It is made sure that these directions do reach the workers, that they understand them and that they are given all needed help in doing the work properly. For doing this, the worker receives, as a premium, an increase of pay which makes it worth his while to co-operate and follow instructions faithfully. In some cases the foremen may also receive a premium which is in proportion to the number of workers who attain the stipulated mark. The foremen cannot bring this about by mere driving, but only by giving genuine help and instruction. But the foreman must always recognize when teaching workers that he is dealing not with angels, nor yet with devils, but with human beings who have been previously trained at some expense and who should be presumed to wish to succeed and are nearly always willing to try if properly handled.

Manufacturing operations have been classified as unsystematized, systematized and scientific. Work may be systematized when it is relatively very simple and with little or no variation, each worker doing the same thing continuously, and using little or no machinery, so that the flow of work is automatic. Cigar-making by hand is an example of such an industry. Also complicated work may be carried through in such large volume as to make possible minute subdivision of it, each worker performing a simple operation upon a single part as it reaches him on a moving conveyor. This last is mass production, and is systematized as an incident to or as a necessary consequence of the volume of the work. But it will be apparent that scientific management differs radically from all of these, not only because it is applicable in some degree to practically every kind of work, but also because, like every true science it is based not upon notions or traditions, but upon facts developed by careful study with a definite object.

Forms and Reports.—Among the blank forms used in scientific management is the work-ticket, on which an assignment of work to be done, and its accomplishment, are recorded, and which, when the specified work has been finished, forms the basis of the pay-roll and of the cost accounting; the *balance of stores* cards, which are the basis of the perpetual inventory and show at all times, not only the stock on hand but when the *order point* for additional material has been reached, and render unnecessary an annual inventory. The use of these and other forms is not, however, scientific management, but only a part of its mechanism. But there must go with these mechanisms that state of mind or that attitude which inspires mutual confidence and a feeling of partnership in an enterprise in which success comes to those who achieve actual results and not through favouritism.

Cost of Idleness.—Though Gantt was not, perhaps, the first to note the great importance of the idleness of equipment, he was the first who called attention to its importance and made manufacturers realize that a machine-tool standing idle is a burden of cost; and to point out that the cost of this idleness should be known to the management, though it should not be included in the cost of the work actually done. All possible effort should be made to reduce the idleness of equipment and, when estimating the cost of work in prospect or determining the cost of what has been done, only charges for the equipment actually used should be made. Entering this cost in the profits and loss account, where it belongs, does not, of course, lessen the actual loss; but it eliminates the chance of self-deception, and brings into view actual facts that are otherwise concealed and often seriously misleading—particularly when preparing cost estimates in competitive business, or in making financial statements.

Influence of Gantt.—Both Taylor and Gantt declined to work with owners who were not willing to share the benefits of improved production with their workers. But with all of Taylor's intellectual keenness and in spite of his excellent intentions he was not a good psychologist. He had difficulty in perceiving why a proposition made by him, and which he believed to be entirely fair and even advantageous to the workers, should not be readily accepted by them, and their co-operation secured forthwith. Gantt, who worked with Taylor for a number of years, was well and broadly educated, but had had no industrial experience. Some time after he had been in practice on his own account, he became consultant to a group of factories in which the so-called *human element* had received much attention. His task was to unify the varying management systems and gradually supplant them with the Taylor system modified somewhat by his personal experience. It soon became apparent that, in order to make satisfactory progress, Gantt had to be relieved of all responsibility for bringing minor executives and employees "into line." Taylor's unmodified system showed weaknesses where it came into contact with foremen who had been in the habit of thinking, making suggestions and having them met with at least appreciative attention. These men lost interest at first and had to be taken in hand by some one whom they knew, and in whom they had confidence. After his work was completed, Gantt declared that this, the largest and most important installation made by him, was also the easiest, and the most successful, because he had the interested co-operation of everyone. Gantt had learned a great truth—that it is better to enlist, at the beginning, the interest of the workers and foremen by giving them recognition and a part to perform. The entry of the United States into the World War forced Gantt into what may be called a new and much better method of approach; one which is in accord with the demonstrated fact that, at least in America, most of the losses called *industrial wastes* are attributable to faults for which management and not the workers, is responsible.

The Gantt Chart is probably the most important contribution to the science of management made by Gantt. The fundamental principle of this chart will be understood from fig. 1, wherein it is assumed that 450 pieces of work are to be machined within a week of 45 working hours. This would mean an average of ten pieces per hour, so that, on this illustrative chart each horizontal space within a full day is taken as representing two hours of working time, also 20 pieces of work to be done. On Monday only 60 pieces were made, and the light horizontal line is accordingly drawn through three spaces to show the work done that day. Also a heavier horizontal, or totalizer, line is drawn below to the same length, or to the point (*a*). Tuesday 70 pieces were finished, and the light line in the Tuesday space is drawn through $3\frac{1}{2}$ horizontal

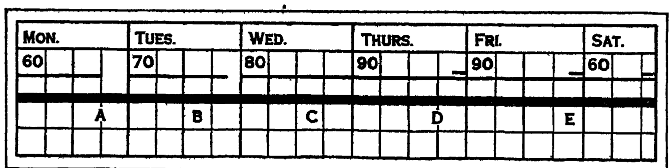

FIG. 1.—ILLUSTRATING THE PRINCIPLE OF THE GANTT CHART

spaces. At the same time the totalizer line is extended $3\frac{1}{2}$ spaces from (*a*) to (*b*) so that it then shows the completion of 130 pieces, or 50 pieces behind the schedule. Wednesday 80 pieces were done; the light line is drawn through the entire space for that day, and the heavy line still shows a shortage of 50 pieces, having been also extended through four spaces to (*c*). For each of the remaining days of the week the production was sufficiently above the schedule to complete the assigned task for the week. Whenever the production runs above the schedule for the day the light line is drawn to the left the proper distance to show the

excess, thus keeping it within its proper time space. In this manner, by means of very simple and easily drawn straight lines, there is available a daily picture of progress and accomplishment with relation to time; and, at any time during the period, the total is clearly indicated.

Fig. 2 is a chart such as is actually used to keep a record of the hours that machines are operated and, when they fall short of the full working period, the reason for it. On this chart there is no

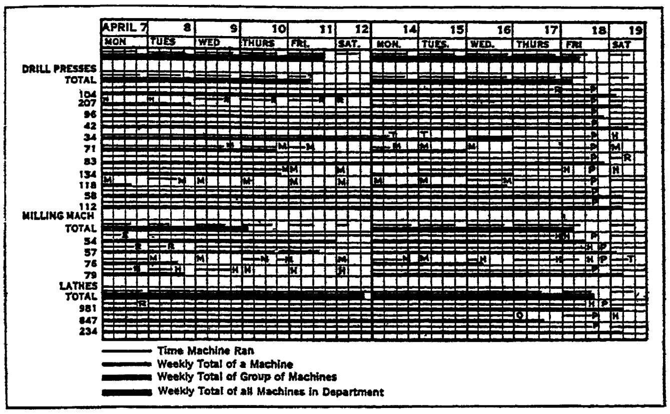

FIG. 2.—GANTT MACHINE RECORD CHART

record of the amount of work done, but only how much of the time the machines are actually operating, how much of it they are idle, and for what reason. Thus drill press 207 is shown to have had no one to operate it on Monday and Tuesday of the first week; Wednesday, Thursday and Friday, it operated only five hours each day, because it needed repairs, as indicated by R. On Saturday it was shut down and thoroughly repaired, so that during the following week it operated full time until Friday, when, as shown by the line of P's, there was trouble with the power which, of course, affected all the machines. Milling-machine 76 suffered mostly from lack of material and 79, from lack of help. Lathe 847 ran out of orders the second Thursday, and had no operator on Saturday. It is obvious that a chart may be ruled for all the working days of a month, or for all the months of a year, and be used to keep constantly within the vision all important facts. The charts are small; 11 x 17 in. (279 x 432 mm.) is a good size.

Man Record Charts.—Records of employees both in comparison with established standards, and with each other, called *man record* charts; records of departments, each by itself, and grouped upon a single chart for comparison; records of expenditures combined with the budget are readily reduced to a convenient size and style, and the general manager of a factory can get, almost instantly, a complete picture of how the work is going.

The Load Chart.—The principle of the Gantt chart can be applied to almost any collective activity. One of its most useful forms is called the *load* chart which shows at a glance the date to which each machine or work space has been loaded with work by the planning department. This is most important when the question of taking on more work arises, making promises of delivery, or deciding whether or not to install additional equipment. Very gratifying results have come from the application of the Gantt chart to purely managerial functions. Not only have such partial installations resulted in important reductions of inventories, but the allotted time between placing an order and its completion has been reduced in some cases to about one-fourth of what it had been. The work of Taylor, and his associates and followers, Gantt, Barth, Cooke and Hathaway has been supplemented by many others, mainly in the way of properly related and harmonious additions, and they have extended the work outside purely industrial operations and into the fields of budgeting, accountancy, sales and marketing and even financing. It is particularly to be noted that the object of scientific management is not to establish a paternal or an eleemosynary relation, but that it is a purely business arrangement, and like all other freely-made business arrangements must be advantageous to both parties. Taylor believed that its benefits would continue to go to employers and workers as long as it was used. That is for the future to decide; but it has proved in application in many cases greatly to the advantage of both worker and employer and does much to keep the peace in industrial fields, pending further advances in our knowledge of how best to get from the earth's resources and equitably distribute the things needed for the support, comfort, progress and happiness of the human family.

SCIENTIFIC MANAGEMENT IN EUROPE

The development of scientific management in Europe may be regarded from two angles. The writings of F. W. Taylor have been translated into most of the European languages. The actual methods and systems which he employed have received attention from a number of leading industrialists in most European countries. Examples are to be found which, allowing for national differences, represent an attempt to apply completely in individual enterprises the management structure outlined in his books. Of greater importance, however, has been the tendency to accept the underlying philosophy which he applied to industrial control. Broadly speaking, that philosophy contemplated the full acceptance of the standards and methods of scientific investigation for the solution of every variety of problem presented by industrial life. It included the whole-hearted application to the tasks of management not only of discoveries in the exact sciences such as physics and chemistry, but of the outlook and work of experimental psychology, physiology, statistics and sociology.

Before the World War.—Prior to 1914 the progress of scientific management in this broader sense was slight. Mention may be made of Hans Renold Ltd. in Great Britain, who had begun to apply Taylor conceptions to their operations. In France Henri le Chatelier, de Frémenville and others introduced Taylor's ideas to their countrymen. On somewhat different lines Henri Fayol started as early as 1900 to publish the results of his long experience as director of the Société de Commentry-Fourchambault. But it was not till 1916 that the appearance of his *Administration industrielle et générale* directed popular attention to his doctrine of administration. This doctrine insisted on the importance of the administrative function, which he analysed into the activities of planning, organizing, directing, co-ordinating and controlling. It has many similarities to Taylor's work.

The period of the World War with its accompanying demand for unprecedented outputs of munitions and other products called into prominence any and every method which might help the nations of Europe in the industrial aspects of the struggle. At the same time considerations of national emergency did much to break down the trade union opposition to changes of method. Following on the strong attack against the Taylor system initiated by the American Federation of Labour, opposition had already assumed considerable dimensions in Europe. Throughout the war years, however, and during the period of reconstruction and boom conditions which followed the Armistice, Governments and industrialists co-operated in the study and application of scientific management. In France a number of professional soldiers placed in charge of munition factories contributed much constructive thought to the application of Taylor's principles, reinforced by their experience of the military services. In Great Britain the report of the Committee on the Health of Munition Workers (1916) and the foundation of the welfare department of the Ministry of Munitions (1917) emphasized the importance of the

scientific approach in dealing with the personnel of industry. There followed the foundation of the Industrial Fatigue Research Board and the National Institute of Industrial Psychology and Physiology. Applications of the exact sciences were covered by the Department of Scientific and Industrial Research, which organized research associations in various industries. The British Engineering Standards Association expanded its well-established activities in the direction of simplification and standardization. One of the pamphlets of the short-lived Ministry of Reconstruction officially recommended the adoption of scientific methods of industrial management. The trade union opposition was, however, still very strong and was reinforced by the demand for the restoration of pre-war union conditions.

In Germany also the period was marked by an increased interest in psycho-technology, and much research was undertaken on fatigue, selection of workers and allied subjects.

After the War.—The severe depression and the period of uncertainty in national finances which followed, delayed developments in the older countries. But in Eastern Europe the new countries which had been established by the Treaty of Versailles made a determined effort to build up their national economy on the most modern lines. The lead was taken by Czechoslovakia. The foundation of the National Academy of Labour at Prague was strongly supported by the Government. It was devoted to the study of scientific management in every aspect. On the initiative of Czechoslovakia a congress was called in 1924, with the active help of Mr. Hoover and the American Engineering council. The greater proportion of the time of this first congress was taken up with a general account of the state of the scientific management movement in the United States. It was therefore more in the nature of a lesson for Europeans than of an international exchange of views. It was attended by representatives from Italy, Czechoslovakia, Poland, Bulgaria, Yugoslavia and Russia. As a result of this congress an International Committee for Scientific Management was established. A further congress took place at Brussels in 1926 in which Belgium, Spain and France also co-operated.

Meanwhile most important developments had been taking place in Germany. An institution was set up under the title of *Reichskuratorium für Wirtschaftlichkeit* (National Council for Scientific Management) which was subsidized by the central Government. It was entrusted with the task of co-ordinating and exercising a general control over a number of national bodies of a technical and scientific character engaged in the study of various applications of science to industry. In this capacity it was given complete authority to distribute all grants for this purpose whether emanating from the Government or from large industrial organizations, grants which amounted in 1926 to more than a million marks. In addition it acts as a propagandist body throughout the whole country, calling attention to the results of scientific investigation by means of the press, special publications, congresses and exhibitions.

Parallel with this movement, the great German industrialists, faced with difficulties following on the stabilization of the mark, were compelled to give close attention to the more logical organization of the whole of their national industry. Their desire to eliminate inefficient plants and to escape from the worst effects of unregulated competition issued in a strong movement in favour of a deliberate attack on their problem by means of amalgamations on a national and international scale. This movement has been given the general title of "rationalization," a term which is at present used alternatively in a wider and a narrower sense. By a great many persons it is taken to imply merely the general tendency to a larger grouping of industrial units in cartels, trusts or combines which has been such a marked feature of industrial life in all European countries since the War. To others, among whom must be included the members of the World Economic Conference, the word connotes the whole of the changed attitude towards economics which looks to a deliberate and scientific control of the processes of production and distribution, whether in the individual works, within a national industry or on an international scale.

During this period encouragement of scientific management on a national scale took place in many other European countries. In Russia the *Central Council for Scientific Management* was established in Moscow and linked up with a wide range of local institutions established throughout the Union of Socialist Soviet Republics. In Italy the *Ente Nazionale Italiano per l'Organizzazione Scientifica del Lavoro* (Italian National Union for Scientific Management) greatly extended its activities with the full support of the Government. It thus became one of the most important instruments of the Fascist Administration in carrying through its programme of national reconstruction. Similar organizations were started in Austria, Belgium, France and Poland.

With the greater stability in national finances and the general improvement in European economic conditions of 1927 the stage was thus set for a forward step. The initiative was provided by a group of internationally-minded Americans who saw, in the theories of industrial management which had proved so valuable to many of their own enterprises, a strong impetus towards European economic recovery. Mr. E. A. Filene and Mr. H. S. Dennison, on behalf of the Twentieth Century Fund, approached the International Labour Office. A careful report on the position of the scientific management movement in Europe was prepared by P. Devinat, an official of the I.L.O. selected for this purpose. As a result of this report the International Management Institute was established at Geneva in the early months of the year, under the joint administration of the International Committee for Scientific Management, the Twentieth Century Fund and the I.L.O. A permanent establishment was thus provided for the comparative study of methods of industrial management on an international scale, and to promote a wider knowledge of scientific management practices.

Two immediate consequences followed. In the first place the documentation prepared for the Industrial Committee of the International Economic Conference on the whole question of rationalization was thorough, comprehensive and authoritative. The resolutions of the conference on the subject constituted a whole-hearted recommendation to traders, industries and Governments all over the world to study and apply the underlying philosophy developed by F. W. Taylor, not only to individual factories but to whole industries, both nationally and internationally, and to every phase of economic life including commerce, agriculture and the home. Thus the full weight of the greatest body of experts in the economic field which has ever been brought together was thrown definitely into the scales in favour of the ideas which Taylor had initiated. European countries which had viewed his practices with doubt and distrust suddenly found that they had received the official sanction and endorsement of the representatives of capital, labour and economic thought, specially convened to discover methods by which European trade might recover from its post-war difficulties.

The effect of these resolutions was very great. The third International Scientific Management Congress, convened at Rome in Sept. 1927 gave evidence of the widespread effort and interest which had been aroused. Over 150 papers were contributed to the proceedings, covering the application of scientific management methods not only to industrial production, but to agriculture, public administration, selling, office management and domestic work. Many of the papers were devoted to the special problems involved in introducing these methods into established organizations. The congress was attended by over 1,400 delegates representing 45 different countries.

The adaptation of scientific management technique to European conditions presents many difficulties. In countries where the standard of living is lower and the opportunities of economic expansion at a rapid rate are less favourable than in the United States, the immediate displacement of workers owing to improved efficiency requires special methods of approach. The psychology both of industrialists and of their employees differs widely from the American model. The consumers as a body are less ready to accept the results of standardized mass production. But on the whole it seems clear that the movement started by Taylor is fairly established in the great majority of industrialized coun-

tries. His ideas are being pursued with a vigour and enthusiasm almost unparalleled in any other department of thought. There is ground for belief that in Europe as in America the claim of his immediate followers will be substantiated. He will come to be regarded as the founder of a second industrial revolution.

(L. U.)

INDUSTRIAL COST ACCOUNTING

Industrial cost accounting is a definite division of accountancy which embodies the analysis, compilation and interpretation of such financial outlays as are necessary for the manufacturing of an article or the carrying on of a specific productive process. By use of this division of accountancy industrial executives are enabled to distinguish profitable units of production from unprofitable ones, to locate wasteful methods of production, to measure deviations from standard performance, to calculate the best methods of material handling and to establish selling prices upon the sound basis of costs of production. All financial outlays expended in the production of an article or a process readily classify into the three distinct cost elements. First are the outlays made for the material that goes into production: such as lumber for the making of desks, pig iron in the smelting of steel, and twine in the producing of nets. Secondly there are the outlays made for the labour that goes into production; such as the wages of varnishers of the desks, the wages of loaders of the open hearth steel furnaces, and the wages of the weavers of the nets. These two elements of material and labour can be directly applied to the specific article or process. The third element of cost, however, embraces all those outlays which by their nature can not be directly identified with any specific article or process. Insurance premiums spent to protect the plant, the dwindling away of the investment by the depreciation of building and equipment, the use of tools, the consumption of lubricants, and the services of supervisory labour—all are indicative of costs that cannot be allied directly with specific units or processes. This third type of outlay is designated as overhead costs.

Distribution of Overhead Costs.—Inasmuch as overhead costs are impossible of direct application, many methods have been developed of indirectly applying them to units and processes. In recent practice the entire plant is divided into small areas each one comprising a specific occupation or plant function. Such divisions have been termed production centres. Each production centre has its definite overhead rate per hour. Thus the time consumed in passing through a specific production centre determines the amount of overhead costs that the article or process must carry. Production centres may be made up of one large machine, such as a large turret lathe; again it may represent a battery of machines such as many drill presses or threaders; or perhaps a production centre may constitute a group of men working with small hand tools at a bench wherein no large machine tools whatsoever are involved. The proportionate amount of overhead costs that a given production centre must carry is based upon many different factors. For instance, floor area may be used for distributing fire insurance costs, heating costs and the like. Metered power consumption of a given production centre may be used in determining what portion of the total costs of operating the power plant should be carried by that production centre. Likewise, by quite similar methods, all overhead costs are distributed to specific production centres. Divide these costs so apportioned by the anticipated productive hours for a given period, say a month, and the hourly rate of the production centre is ascertained.

Types of Cost Systems.—Two systems are found in industry, one known as a job-order system, whereby costs are determined for the special articles or services purchased by a specific customer. The building of a bridge or the construction of a special piece of apparatus represents the type of manufacturing calling for a job-order cost system.

In point of contrast the process cost system is used in industries where a standard article is produced and where the articles are made for stock and sale, regardless of any particular purchaser. Automobiles (except custom-built) or electric bulbs are types of commodities calling for a process cost system. With the rise in standardization, the shift to process costs is becoming very pronounced, and with the shift comes a new use of industrial cost accounting. When uniformity in units made is once established, then standards are developed for each kind of work performed. These standards constitute quotas that are to be approximated by the different operating divisions. From this development it is but one step further in setting up standard costs prior to production taking place. Following the production, actual cost experience is compared with the pre-determined cost standards. The costs of selling the articles produced, also the costs of the general administration of an enterprise, are not as yet distributed to specific articles in most industrial establishments. Great strides, however, are being made by the more progressive firms in having both selling and administration costs allocated to specific articles or processes. Cost data to be of value in plant control must be presented in such a shape as will meet the specific needs of the different plant managers who need cost compilations. A general manager, for instance, will require an entirely different presentation from that required by a minor foreman or a research chemist.

SCIENTIFIC METHOD is a collective term denoting the various processes by the aid of which the sciences are built up. In a wide sense, any mode of investigation by which scientific or other impartial and systematic knowledge is acquired is called a scientific method. Such methods are of two principal types—technical and logical. A *technical* or technological *method* is a method of manipulating the phenomena under investigation, measuring them with precision, and determining the conditions under which they occur, so as to be able to observe them in a favourable and fruitful manner. A *logical method* is a method of reasoning about the phenomena investigated, a method of drawing inferences from the conditions under which they occur, so as to interpret them as accurately as possible. The term "scientific method" in the first instance probably suggests to most minds the technical methods of manipulation and measurement. These technical methods are very numerous and they are different in the different sciences. Few men ever master the technical methods of more than one science, or one group of closely connected sciences. An account of the most important technical methods is usually given in connection with the several sciences. It would be impossible, even if it were desirable, to give a useful survey of all, or even of the most important, technical methods of science. It is different with the logical methods of science. These methods of reasoning from the available evidence are not really numerous, and are essentially the same in all the sciences. It is both possible and desirable to survey them in outline. Moreover, these logical methods of science are in a very real sense the soul of the technical methods.

In pure science the technical methods are not regarded as an end in themselves, but merely as a means to the discovery of the nature of the phenomena under investigation. This is done by drawing conclusions from the observations and experiments which the technical methods render possible. Sometimes the technical methods make it possible for the expert investigator to observe and measure certain phenomena, which otherwise could either not be observed and measured at all, or not so accurately. Sometimes they enable him so to determine the conditions of their occurrence

that he can draw reliable conclusions about them, instead of having to be content with unverified conjectures. The highly speculative, mainly conjectural character of early science was no doubt due entirely to the lack of suitable technical methods and scientific instruments. In a sense, therefore, it may be said that the technical methods of science are auxiliary to the logical methods, or methods of reasoning. And it is these methods that are to be considered in the present article. The technical methods of science, as ought to be clear from the preceding remarks, are of first rate importance, and we have not the remotest desire to underrate them; but it would be futile to attempt to survey them here.

Some Mental Activities Common to All Methods.—There are certain mental activities which are so absolutely indispensable to science that they are practically always employed in scientific investigations, however much these may vary in other respects. In a wide sense these mental activities might consequently be called methods of science, and they are frequently so called. But this practice is objectionable, because it leads to cross division and confusion. What is common to all methods should not itself be called a method, for it only encourages the effacing of important differences; and when there are many such factors common to all the methods, or most of them, confusion is inevitable. When the mental activities involved are more or less common to the methods, these must be differentiated by reference to other, variable factors—such as the different types of data from which the inferences are drawn, and the different types of order sought or discovered in the different kinds of phenomena investigated—the two sets of differences being, of course, intimately connected. The mental activities referred to are the following: Observation (including experiment), analysis and synthesis, imagination, supposition and idealization, inference (inductive and deductive), and comparison (including analogy). A few words must be said about each of these; but no significance should be attached to the order in which they are dealt with.

Observation and Experiment.—Observation is the act of apprehending things and events, their attributes and their concrete relationships. From the point of view of scientific interest two types of observation may be distinguished, namely: (1) The *bare observation* of phenomena under conditions which are beyond the control of the investigator, and (2) *experiment,* that is, the observation of phenomena under conditions controlled by the investigator. What distinguishes experiment from bare observation is *control* over what is observed, not the use of scientific apparatus, nor the amount of trouble taken. The mere use of telescopes or microscopes, etc., even the selection of specially suitable times and places of observation, does not constitute an experiment, if there is no control over the phenomenon observed. On the other hand, where there is such control, there is experiment, even if next to no apparatus be used, and the amount of trouble involved be negligible. The making of experiments usually demands the employment of technical methods, but the main interest centres in the observations made possible thereby. The great advantage of experiment over bare observation is that it renders possible a more reliable analysis of complex phenomena, and more reliable inferences about their connections, by the variation of circumstances which it effects. Its importance is so great that people commonly speak of "experimental method." The objection to this is that experiment may be, and is, used in connection with various methods, which are differentiated on other, and more legitimate, grounds. To speak of a method of observation is even less permissible, seeing that no method can be employed without it.

Analysis and Synthesis.—The phenomena of nature are very complex and, to all appearances, very confused. The discovery of any kind of order in them is only rendered possible by processes of analysis and synthesis. These are as essential to all scientific investigation as is observation itself. The process of analysis is helped by the comparison of two or more objects or events that are similar in some respects and different in others. But while comparison is a necessary instrument of analysis, analysis, in its turn, renders possible more exact comparison. After analysing some complex whole into its parts or aspects, we may tentatively connect one of these with another in order to discover a law of connection, or we may, in imagination, combine again some of them and so form an idea of what may be common to many objects or events, or to whole classes of them. Some combinations so obtained may not correspond to anything that has ever been observed. In this way analysis and synthesis, even though they are merely mental in the first instance, prepare the way for experiment, for discovery and invention.

Imagination, Supposition and Idealization.—Such order as may be inherent in the phenomena of nature is not obvious on the face of them. It has to be sought out by an active interrogation of nature. The interrogation takes the form of making tentative suppositions, with the aid of imagination, as to what kind of order might prevail in the phenomena under investigation. Such suppositions are usually known as hypotheses, and the formation of fruitful hypotheses requires imagination and originality, as well as familiarity with the facts investigated. Without the guidance of such hypotheses observation itself would be barren in science, for we should not know what to look for. Mere staring at facts is not yet scientific observation of them. Hence for science any hypothesis, provided it can be put to the test of observation or experiment, is better than none. For observation not guided by ideas is blind, just as ideas not tested by observations are empty. Hypotheses that can be put to the test, even if they should turn out to be false, are called "fruitful"; those that cannot be so tested, even if they should eventually be found to be true, are for the time being called "barren." Intimately connected with the processes of imagination and supposition is the process of idealization, that is, the process of conceiving the ideal form or ideal limit of something which may be observable but always falls short, in its observed forms, of the ideal. The use of limiting cases in mathematics, and of conceptions like those of an "economic man" in science are examples of such idealization.

Inference.—This is the process of forming judgments or opinions on the ground of other judgments or on the evidence of observation. The evidence may be merely supposed for the sake of argument, or with a view to the further consideration of the consequences which follow from it. It is not always easy to draw the line between direct observation and inference. People, even trained people, do not always realize, *e.g.,* when they pass from the observation of a number of facts to a generalization which, at best, can only be regarded as an inference from them. But the difficulty need not be exaggerated. There are two principal types of inference, namely deductive and inductive. *Inductive inference* is the process of inferring some kind of order among phenomena from observations made. *Deductive inference* is the process of applying general truths or concepts to suitable instances. In science inductive inference plays the most important role, and the methods of sciences are mainly instruments of induction or auxiliaries thereto. But deductive inference is also necessary to science, and is, in fact, a part of nearly all complete inductive investigations. Still, marked inductive ability is very rare. There are thousands who can more or less correctly apply a discovery for one who can make it.

Comparison and Analogy.—Reference has already been made to the importance of the process of comparison in the mental analysis of observed phenomena. The observation of similarities and differences, aided by the processes of analysis and synthesis, is one of the first steps to knowledge of every kind, and continues to be indispensable to the pursuit of science throughout its progress. But there are degrees of similarity. Things may be so alike that they are at once treated as instances of the same kind or class. And the formulation and application of generalizations of all kinds are based upon this possibility of apprehending such class resemblances. On the other hand, there is a likeness which stops short of such close class likeness. Such similarity is usually called analogy. The term is applied to similarity of structure or of function or of relationship, in fact, to similarity of almost every kind except that which characterizes members of the same class, in the strict sense of the term. And analogy plays a very important part in the work of science, especially in suggesting those suppositions or hypotheses which, as already explained,

are so essential to scientific research and discovery. As the subject is discussed in the article ANALOGY, no more need be said about it here.

After this brief survey of various mental activities which are more or less involved in the pursuit of every kind of knowledge, and consequently form no suitable bases for the differentiation of the various methods of science, we may now proceed to the consideration of the several scientific methods properly so called.

Classification.—This may be described as the oldest and simplest of scientific methods. The observation of similarities between certain things, and classing them together, marks the earliest attempt to discover some kind of order in the apparently chaotic jumble of things that confront the human mind. Language bears witness to the vast number of classifications made spontaneously by pre-scientific man. For every common noun expresses the recognition of a class; and language is much older than science. The first classifications subserved strictly practical purposes, and had reference mainly to the uses which man could make of the things classified. They were frequently also based on superficial resemblances which veiled deeper differences, or were influenced by superficial differences which diverted attention from deeper similarities. But with the growth of the scientific spirit classifications became more objective or more natural, attention being paid to the objective nature of the things themselves rather than to their human uses. Even now scientific classification rarely begins at the beginning, but sets out from current classifications embodied in language. It has frequent occasion to correct popular classifications. At the same time it has difficulties of its own, and more than one science has been held up for centuries for want of a really satisfactory scheme of classification of the phenomena constituting its field of investigation. To recognize a class is to recognize the unity of essential attributes in a multiplicity of instances; it is a recognition of the one in the many. To that extent it is a discovery of order in things. And although it is the simplest method of science, and can be applied before any other method, it is also the fundamental method, inasmuch as its results are usually assumed when the other methods are applied. For science is not, as a rule, concerned with individuals as such, but with kinds or classes. This means that the investigator usually assumes the accuracy of the classification of the phenomena which he is studying. Of course, this does not always turn out to be the case. And the final outcome of the application of other methods of science to certain kinds of phenomena may be a new classification of them.

The Evolutionary or Genetic Method.—When classifying things according to their present similarities and differences it sometimes happens that one is impressed by certain resemblances between things, although these cannot be regarded as belonging to the same class. In such cases the suggestion sometimes forces itself upon the mind of the investigator that these similar yet different classes of things may be descendants of a common ancestry. And, if he inclines to the general feasibility of the idea of evolution in some sense or other, he will feel confronted with a new problem, namely, that of tracing the stages in the descent or evolution of the kindred classes. This applies especially to the study of living things and their creations, including human customs, institutions, discoveries and inventions. This method of investigation is commonly known as the genetic or evolutionary method. Wherever it is applied with success it affords a deeper insight into the unity and continuity of certain kinds of facts than is afforded by the above-mentioned method of classification. Sometimes, indeed, the real significance of the resemblances on which ordinary classification is based is brought to light first by the genetic method, which shows the similar classes to be different stages or phases of a system of continuous or intimately connected differentiations.

The application of the genetic method is directed to the discovery of two things, namely: (1) the main stages through which the evolution of the facts under investigation has probably passed, and (2) the causes which produced the various changes constituting the several phases in the suggested course of evolution. In dealing with the first of these problems, namely the discovery of the main stages or gradations of an evolutionary series, the correct procedure, according to Darwin, is to seek them, in the first instance, among kindred classes of objects. But it is rarely possible to secure sufficient evidence from a study of the nearest kindred only. The investigator is, consequently, often compelled to seek farther afield for missing links in the probable chain of evolution. Thus, *e.g.*, Darwin himself, when investigating the evolution of the honeycomb of the hive-bee, kept closely to kindred species; but when he traced the evolution of the eye of vertebrates he went far afield, and invoked the help of facetted eyes, eyes without a lens, and eyes that are mere aggregates of pigment cells. Similarly, the comparative psychologist, when tracing the evolution of the human mind, does not confine his attention to the higher apes (the primates), but seeks light also from the lower animals, going even to the ant to learn of its ways. The second of the aforementioned tasks of the genetic method, namely, the determination of the causes which may have produced the various changes constituting the series of evolutionary stages, is mostly very difficult. A purely mechanistic explanation seems out of the question. In opposition to it there has been put forward the view of emergence (*q.v.*) or of *creative evolution* (*q.v.*). These views may be a healthy reaction against mechanistic pretensions; but they run the risk of confusing the christening of a problem with the solution of it.

The term "comparative method" is sometimes used as the equivalent of the evolutionary or genetic method just explained; but sometimes, perhaps more frequently, it is used in the rather ambiguous and indiscriminate sense of "the method of the comparative sciences," such as comparative philology, comparative anatomy, sociology, etc. These sciences, however, employ a variety of methods sometimes including the evolutionary method, and sometimes not. All they seem to have in common is a process of comparison. But, as already explained, comparison is no distinctive method, but rather an activity common to every method and want of method.

Methods for Discovering Causal Connections.—The method of classification and the evolutionary method satisfy to some extent the human quest for order, which is prompted mainly by the need of anticipation as a means to adaptation. Successful classification means a knowledge of the more or less uniform coexistence of certain attributes in the things concerned, so that it is possible to infer the presence of certain unobserved class-characteristics from certain others which are more accessible to observation—say the possession of a ruminant stomach in a quadruped having hoofs and frontal horns. The successful application of the genetic method means the possibility of inferring later stages from the present stage of an evolutionary series. But such uniformities are not the most reliable or most important for science or for life. Another and more important kind of uniform connection, perhaps the most important kind of uniform connection discoverable, is the causal connection between things or events. The general characters of causal connection is discussed in the article CAUSALITY, and an idea of it will be assumed here. To discover causal connection is to discover uniform connections between certain physical antecedents and certain consequents. Now, natural events do not disclose their causal connections to mere inspection. These connections can only be inferred or guessed from the observation of certain kinds of sequences or concurrences. The general character of the kind of observations which suggest causal connections, or confirm such suggestions, have been formulated in certain canons of induction, which are commonly known as the five simpler inductive methods. But there are also certain other methods of tracing causal connections, notably the statistical method, and certain combinations of the simpler inductive methods and deductive reasoning which may be called collectively the deductive-inductive method. We shall now proceed to deal with these methods in turn.

THE FIVE SIMPLER INDUCTIVE METHODS

These are based on our assumption that things and events are not a mere matter of chance, but are, in the main at least, the results determined by certain operative conditions, and occur only when these conditions operate. If, then, while other things remain

essentially the same, a certain factor or circumstance cannot be omitted, or changed in quantity, without affecting the phenomenon under investigation, it may be concluded that the factor or circumstance in question is an indispensable condition of that phenomenon, that is to say, is causally connected with it. On the other hand, any circumstance the absence, or quantitative variation, of which appears to make no difference to the phenomenon under investigation may be regarded as having no causal connection with it. It is necessary, therefore, to observe instances of the phenomenon concerned under circumstances as varied as possible, in order to find out from such observations what can and what cannot be removed or altered without affecting it. The procedure may assume one of two principal forms—a direct and an indirect form. In the direct form it is shown by observation or experiment: (1) that the elimination of a certain factor or antecedent is followed by the non-appearance of the phenomenon concerned, or (2) that a quantitative change in a certain factor or antecedent is followed by a quantitative change in that phenomenon, although, in either case, all other relevant factors remained the same. The first of these direct forms (1) is known as the Method of Difference, the second (2) is known as the Method of Concomitant Variations. The indirect form of this procedure consists in showing that so long as a certain antecedent or factor is present, a certain result seems to follow, and is not materially affected by changes in any of the other factors or circumstances that might appear to be relevant; and from this it is concluded that the phenomenon is not causally connected with the variable antecedents, but, since it must be causally connected with something, that it is so connected with the factor or antecedent that was present in all the observations made. This indirect method is known as the Method of Agreement. Of the two other methods belonging to this group, one, known as the Method of Residues, is only a modification of the Method of Difference, and the other known as the Joint Method of Agreement and Difference, is really the Method of Agreement supplemented by the study of certain negative instances so as to approximate to some extent to the Method of Difference.

The several methods have different degrees of cogency. The Methods of Difference and of Concomitant Variations are the most satisfactory; that of Agreement is least satisfactory. But the choice of method is not left entirely to the discretion of the investigator. Each method can only be applied to certain kinds of instances. And when the kind of instances required for the application of the most cogent method cannot be found, or produced, the investigator must perforce resort to the next best method, and so on. Sometimes, indeed, he may even find it necessary to apply rather loosely several of these methods to the same problem, and even then perhaps he may seek confirmation in deductive reasoning from the nature of the case in the light of accepted truths. We shall now formulate and explain each of the five methods separately.

The Method of Difference.—If two sets of circumstances are alike in all relevant respects, except that in one of them (the positive instance) a certain antecedent is present and a certain consequent follows, whereas in the other (the negative instance) both are absent, then that antecedent and that consequent are causally connected, that is to say, the consequent may always be expected to follow that antecedent in the absence of counteracting conditions. Using (here and throughout) the early letters of the alphabet to represent antecedents, the later letters to represent consequents, dots to represent the presence of irrelevant circumstances, and an arrow (→) to mean "is followed by," or "is causally connected with," the Method of Difference may be symbolized as follows: $a\ b\ c\ d. . . \rightarrow w\ x\ y\ z. . .$; $a\ b\ c. . . \rightarrow w\ x\ y$; $\therefore d \rightarrow z$. The instances compared may be two separate instances; or they may only be successive states of the same group of circumstances from which something is removed in order to obtain the negative instance, or to which something is added in order to obtain the positive instance; or, lastly, each instance may consist of a group of things. But in all cases the two instances must be as like as possible in all essentials, except in regard to the difference under investigation. The significance of a certain *difference* between instances can only be determined when the instances are *as like as possible in other respects*. The neglect of this precaution (known as the fallacy *non ceteris paribus*) easily leads to the attribution of an effect to the wrong antecedent (the fallacy of *post hoc ergo propter hoc*).

The Method of Concomitant Variations.—If a quantitative change in a certain antecedent is followed by a quantitative change in a certain consequent, although no other relevant circumstance has changed, then the antecedent and the consequent are causally connected. Symbolically, $a\ b\ c\ d_1 . . . \rightarrow w\ x\ y\ z_1 . . .$; $a\ b\ c\ d_2 . . . \rightarrow w\ x\ y\ z_2 . . .$; $a\ b\ c\ d_3 . . . \rightarrow w\ x\ y\ z_3 . . .$ [or briefly, z is a function of $d_1 z=f(d)$]; $\therefore d \rightarrow z$. This method may easily be expressed in a form that will show its kinship with the method of difference, the mere presence of a certain quantitative difference in the antecedent (d_1-d_2) being followed by a quantitative difference in the consequent (z_1-z_2). But, of course, the method of concomitant variations has no absolute negative instance such as the method of difference has. The tendency of modern science to become increasingly quantitative has given special importance to the method of concomitant variations as the instrument of *quantitative induction*, that is, for the establishment of precise quantitative correlations between phenomena, even when they are already known to be causally connected, or even when no interest attaches to the question of their causal connection. The concomitant variation may, of course, be either direct or inverse, that is, the consequent may increase with an increase in the antecedent, and diminish when it diminishes, or the consequent may diminish as the antecedent increases, and increase when it diminishes. And the proportion, in either case, may be quite simple or extremely complicated.

The Method of Agreement.—If several instances of a phenomenon have one relevant antecedent in common, then the common antecedent is causally connected with that phenomenon. Symbolically, $a\ b\ c\ d . . . \rightarrow w\ x\ y\ z . . .$; $b\ d\ f\ g . . . \rightarrow x\ z\ s\ t . . .$; $d\ f\ k\ l . . . \rightarrow z\ s\ p\ r . . .$; $\therefore d \rightarrow z$. It should be noted carefully that the instances required for the application of this method are instances that are as different from each other as possible except in regard to the common factor or antecedent which is under investigation. Just as the difference between instances is only significant when the instances are very similar in other respects, so the agreement or similarity between instances is significant only when the instances are as different as possible in other respects. A thousand instances which agree in everything would be no better, no more instructive, than one of them. The main precautions to be borne in mind when applying the method of agreement are the following: (1) To make sure that no relevant circumstance is overlooked; (2) Not to regard different consequents as similar, and assign them all to a common antecedent, merely because they may all serve more or less the same practical purpose; (3) To remember that the antecedent and consequent may have no direct causal connection, but may both be the consequents of some other antecedents.

The Method of Residues.—If part of a complex effect can be accounted for by reference to certain antecedents which are known to be, or to have been, present, and the consequents of which are already known from previous investigations, then the residue of the complex effect must be causally connected with the rest of the antecedents. Symbolically, $a\ b\ c\ d . . . \rightarrow w\ x\ y\ z . . .$; $(a\ b\ c \rightarrow w\ x\ y)$; $\therefore d \rightarrow z$. Sometimes these other antecedents are known to be present, but their precise effect has not yet been determined. At other times their presence is not suspected until the residual phenomenon compels the investigator to search for them. These latter cases are, perhaps, the most important, as they often lead to important discoveries. It was, *e.g.*, the residual weight or density of atmospheric nitrogen (as compared with nitrogen obtained from nitrous oxide, etc.), that led to the discovery of argon, and it was the residual deviation in the orbit of Uranus that led to the discovery of Neptune.

The Joint Method of Agreement and Difference.—If a group of instances in which a certain phenomenon occurs have only one relevant antecedent in common, while another group of otherwise similar instances in which the phenomenon does not

occur have nothing relevant in common except the absence of the common antecedent of the first group, then that antecedent is causally connected with that phenomenon. Symbolically, positive group: $a\ b\ c\ d \ldots \rightarrow w\ x\ y\ z \ldots$; $b\ d\ f\ g \ldots \rightarrow x\ z\ s\ t \ldots$; $d\ f\ k\ l \ldots \rightarrow z\ s\ p\ v \ldots$; negative group: $b\ c\ f \ldots \rightarrow x\ y\ s \ldots$; $b\ g\ k \ldots \rightarrow x\ t\ p \ldots$; $c\ l\ a \ldots \rightarrow y\ v\ w \ldots$; therefore $d \rightarrow z$. The positive group consists of instances such as are required for the method of agreement. The negative group, it should be noted carefully, does not contain any instance that, in conjunction with one of the positive instances, would enable one to apply the method of difference. But still the observation of such negative instances does strengthen the conclusion suggested by the positive instances, namely, by eliminating the possibility of plurality of causes in the positive instances (that is to say, the possibility that in each of the positive instances the common effect was produced by a different antecedent, not by the common antecedent). By treating each whole group as if it were one instance, we get here an approximation to the group form of the method of difference.

Note on "Relevance."—It may have been noticed that in the formulation of each of the simpler inductive methods reference was made to "relevant" factors or antecedents. The qualification is very important. Every event or change occurs in an infinitely complex setting, and it is only in so far as the vast majority of antecedents and accompaniments of any phenomenon can be safely ignored that it is possible to apply these and other methods at all. Of course, mistakes are sometimes made, and some thing that is dismissed or ignored as irrelevant may turn out to be most relevant. A warning to this effect had to be especially emphasized in connection with the Method of Agreement, for instance. The question therefore arises as to how it can be known whether an antecedent or circumstance is relevant or not. No general, fool-proof test can be suggested. In every inductive investigation, common sense, accumulated experience and knowledge, some originality, and a spirit of adventure are indispensable. Nothing, not even a study of scientific method, can serve as a substitute for these things. One can only indicate briefly how investigators are commonly guided in discriminating between what is likely to be relevant and what is likely to be irrelevant. The most important clue is that afforded by previous knowledge. Antecedents and circumstances the effects of which are already known, and are known to be different from the phenomenon under investigation, are generally dismissed as irrelevant, unless there is some *prima facie* ground for suspecting that they may be influencing it to some extent by way of modification or resistance. In this way the knowledge of what is relevant, like every other part of human knowledge, can only be improved or confirmed by more knowledge. Another clue is almost too vague for precise description, yet its influence is very real. It just consists of a vague feeling, or intuition, that certain things are relevant and others are not. This "feeling in our marrow" is probably an outcome of previous experience that has not yet emerged into articulate thought. Its very vagueness shields it from critical scrutiny. No wonder that it sometimes misleads. However, there it is, and a wise man makes the best of things, keeping an open and alert mind, and wasting no tears over the absence of sure signs and fool-proof criteria.

The Statistical Method.—The simpler inductive methods already described, and the Deductive-Inductive Method, which will be dealt with presently, can only be applied to phenomena that can be adequately analysed, and examined under sufficiently varied conditions or circumstances. But these requirements are not always satisfied. Many phenomena—meteorological, biological, medical, social, economic—are too complicated for adequate analysis, and are not observable under sufficiently varied or controlled conditions for the reliable application of these methods. In such cases, popular thought, impelled sometimes by practical needs and sometimes by sheer inability to suspend judgment, usually resorts to the so-called *Method of Simple Enumeration*. That is to say, it assumes a causal connection between any things or events between which a concurrence or sequence has been observed on a number of occasions. No attempt is made to discover exceptions or to study the phenomena under sufficiently varied circumstances. It is a loose habit of thought, or of thoughtlessness, rather than a scientific method. Most popular fallacies and superstitions are its offspring. Now, the Statistical Method is an attempt to deal with such complex and exceptionally difficult, phenomena in a scientific manner. It has several distinguishable functions. Its first and main business is to tidy up vast masses of varied data or material, so as to make them suitable for practical, or for scientific use. In this way it embraces such interests as the practical requirements of insurance companies, etc., and is a useful auxiliary to the methods of classification (which it furnishes with concise quantitative descriptions of classes of variable phenomena) and to other scientific methods. But here we are concerned with it mainly as an independent method of science for ascertaining connections between such phenomena as cannot be studied adequately by the other methods of science. The details of statistical technique are explained in the article STATISTICS. Here it is only proposed to sketch in outline the general character of statistical method as one of the methods of science.

Like other scientific methods statistical method aims at the discovery of connections between natural phenomena. And it does so by a close study of their concurrences or sequences. Unlike the so-called method of simple enumeration, it notes and records carefully not only actual concurrences and sequences, but also exceptions; it makes observations over as large and varied a field as possible; and cautiously draws conclusions that will fit *all* the observed facts. The observation of only a few cases of concurrence, or sequence, or concomitant variation, among certain phenomena, especially when the conditions are not under control and the full circumstances are not known, makes it impossible to distinguish a causal connection between the phenomena from a casual coincidence between them. But the observation of a large number of cases over a wide and varied range of circumstances, an exact record of positive and negative cases, and of variations between series of instances, may justify a highly probable conclusion about a causal connection between the phenomena concerned. The assumption on which the statistical method proceeds is this: If two phenomena, say A and B are not really connected, then their concurrence (or sequence, or concomitant variation) is a mere coincidence. In that case, the concurrence, etc., of B with other things than A should, as a matter of probability, be about as frequent as with A. But if the concurrence, etc., of B with A is appreciably greater than with things other than A, then the two are probably connected. Such greater concurrence of B with A than with *non-A* is called their correlation or association (according as the reference is to "variables," that is, things that can be present in various measurable magnitudes, or "attributes," that is, what can only be present or absent, what can be counted but not measured). And the main line of enquiry by means of statistical method, as an independent method of science, is into correlations and associations as clues to causal connections. The degree of such correlation or association may vary considerably, and is expressed by certain "co-efficients." When it is complete we get a general law of the ordinary type (*If A, then B*); if partial we get what is more especially called a statistical law stating that B occurs in such and such a percentage of cases of A, or $A = c\ (B)$, where c stands for some ascertained constant.

In view of the tendency to exaggerate the importance of statistical method as an independent method of science, it may, perhaps, be well to point out that it is only one of the methods of science, and really only a substitute for more cogent methods when these are inapplicable, for reasons already indicated. This seems obvious from the fact that as soon as the law of certain phenomena is discovered (by the other methods mainly) there is no further use for the statistical method in that field of enquiry. There was a time, for instance, when statistical records were kept of solar and lunar eclipses, just as they are still kept of meteorological phenomena. These records were useful and valuable, for they enabled the ancients already to note certain empirical cycles on which they could base fairly accurate anticipations of

eclipses, although they did not understand them. But since the laws of the occurrence of eclipses have been discovered there is no further need of statistical records of them—they can be foretold with accuracy and confidence. This, of course, does not affect the great value of statistical method as one of the methods of science, and as an auxiliary to the others. The important thing to bear in mind is that no amount of statistical technique can serve as an adequate substitute for a direct knowledge of, and familiarity with, the phenomena under investigation.

The Deductive-inductive Method.—Just as money makes money, so knowledge already acquired facilitates the acquisition of more knowledge. This fact has already been illustrated above in connection with the method of residues, etc. It is equally evident in the case of the method which will now engage our attention. The progress of science, and of knowledge generally, is frequently facilitated by supplementing the simpler inductive methods by deductive reasoning from knowledge already acquired. Such a combination of deduction with induction, J. S. Mill called the "Deductive Method," by which he really meant the "Deductive Method of Induction." To avoid the confusion of the "Deductive Method" with mere deduction, which is only one part of the whole method, it is better to describe it as the "Deductive-Inductive Method" or the "Inductive-Deductive Method." Mill distinguished two principal forms of this method as applied to the study of natural phenomena, namely, (1) that form of it in which deduction precedes induction, and (2) that in which induction precedes deduction. The first of these (1) he called the "Physical Method"; the second (2) he called the "Historical Method."

These names are rather misleading, inasmuch as both forms of the method are frequently employed in physics, where sometimes, say in the study of light, mathematical (*i.e.*, deductive) calculations precede and suggest physical experiments (*i.e.*, induction), and sometimes the inductive results of observation or experiment provide the occasion or stimulus for mathematical deductions. In any case, the differences in order of sequence are of no great importance, and hardly deserve separate names. What is of importance is to note the principal kinds of occasion which call for the use of this combined method. They are mainly three in number: (1) When an hypothesis cannot be verified (*i.e.*, tested) directly, but only indirectly; (2) when it is possible to systematize a number of already established inductions, or laws, under more comprehensive laws or theories; (3) when, owing to the difficulties of certain problems, or on account of the lack of sufficient and suitable instances of the phenomena under investigation, it is considered desirable either to confirm an inductive result by independent deductive reasoning from the nature of the case in the light of previous knowledge, or to confirm a deductive conclusion by independent inductive investigation.

An example of each of these types may help to make them clear. (1) When Galileo was investigating the law of the velocity of falling bodies he eventually formed the hypothesis that a body starting from rest falls with a uniform acceleration, and that its velocity varies with the time of its fall. But he could not devise any method for the direct verification of this hypothesis. By mathematical deduction, however, he arrived at the conclusion that a body falling according to his hypothetical law would fall through a distance proportionate to the time of its fall. This consequence could be tested by comparing the distances and the time of falling bodies, which thus served as an indirect verification of his hypothesis. (2) By inductions from numerous astronomical observations made by Tycho Brahe and himself, Kepler discovered the three familiar laws called by his name, namely, (*a*) that the planets move in elliptic orbits which have the sun for one of their foci; (*b*) that the velocity of a planet is such that the radius vector (*i.e.*, an imaginary line joining the moving planet to the sun) sweeps out equal areas in equal periods of time; and (*c*) that the squares of the periodic times of any two planets (that is, the times which they take to complete their revolutions round the sun) are proportional to the cubes of their mean distances from the sun. These three laws appeared to be quite independent of each other. But Newton systematized them all in the more comprehensive induction, or theory, of celestial gravitation. He showed that they could all be deduced from the one law that the planets tend to move towards each other with a force varying directly with the product of their masses, and inversely with the square of the distances between them. (3) H. Spencer, by comparing a number of predominantly industrial States and also, of predominantly military States, ancient and modern, inferred inductively that the former type of State is democratic and gives rise to free institutions, whereas the latter type is undemocratic and tends to oppression. As the sparse evidence hardly permitted of a rigorous application of any of the inductive methods, Spencer tried to confirm his conclusion by deductive reasoning from the nature of the case in the light of what is known about the human mind. He pointed out that in a type of society which is predominantly industrial the trading relations between individuals are the predominant relations, and these train them to humour and consider others. The result is a democratic attitude in all. In a State which is predominantly military, the relations which are most common among its members are those of authority, on the one part, and of subordination on the other. The result is the reverse of a democratic atmosphere.

Inductive Methods and Their Postulates.—All the methods of science start from observed facts, and usually end in some kind of generalization relating to a whole class of facts or events, or a large group of them. The number of instances actually observed is never more than a very small percentage of the whole class or group to which the generalization is extended. The question therefore arises as to the justification of such generalization from a limited number of observations. Even if we assume that there is law and order among natural phenomena this does not yet answer our question. It is probably impossible to offer a complete justification of scientific induction in this respect. As a matter of fact, certain assumptions are usually made, wittingly or unwittingly, both in science and in practical life. And all one can do is to state these assumptions or postulates explicitly, and hope that, to some extent at least, they are the result of a long process of adaptation of human thought to the nature of things. The first of these assumptions is that it is possible with reasonable care to select as samples from a group, or a class, that will fairly represent the whole group or class. This assumption is known as the *Principle of Fair Samples*. In order to obtain a fair sample, the selection must be made in a way that is calculated to avoid onesidedness or bias. In that sense such a sample is often described as a *random* sample; but the selection of such a sample usually calls for much knowledge and insight as to the best way of avoiding bias. The reliability of a sample can never be more than probable, and the degree of this probability varies with the size and variety of the sample—the actual number being less important than the variety, whenever there is reason to suspect variation in the whole that is to be judged by the sample. Much depends on our experience of the phenomena in question. In some cases a single instance (observed, say, under conditions of the method of difference) may be deemed to be a fair sample, in other cases even a large sample may fail to inspire confidence. This brings us to the second assumption. In cases of strict generalizations or uniformities (as distinguished from partial statistical laws), inferred inductively by means of one of the more reliable inductive methods, what happens is really this: The conditions under which the observations are made are such as to show that *in the particular cases observed* certain antecedents are causally connected with certain consequents. The generalization that all antecedents of that kind are causally connected with consequents of that kind is made so spontaneously that most people hardly realize that they have made it. But, strictly speaking, the generalization is an additional inference over and above the inference concerning the connection in the particular cases observed. And here again one cannot strictly justify it, but only state explicitly the assumption on which it rests. The assumption is that what is found to be a sufficient reason in one instance must be a reason in all instances of that kind. This assumption I have called the *Principle of the Uniformity of Reasons.*

Scientific Method and Scientific Explanation.—All the methods of science are essentially methods of discovering order in natural phenomena. For it is the ultimate aim of science to discover order in nature. To discover order in any class or group of phenomena is to explain them; that is, to make them clearer, more intelligible. Conversely, to explain anything is to indicate its place in some orderly system. In a broad sense it may be said that explanation generally takes the form of tracing the one in the many, or identity amid differences (*see* the article EXPLANATION). Still, there are different types of explanation, and their differences are worth noting. As might have been expected, there is a general correspondence between the several kinds of scientific method and the several types of explanation, as will appear from what follows. The main types of explanation may be summarily indicated under a few heads. (1) *Reference to a Class.* Sometimes an object is explained when it is allocated to its class, especially if the class is already known. If, *e.g.*, one is in doubt about the character of a plant, it is explained by finding out to what species or variety, etc., it belongs, or if one is puzzled by a certain flash of light it may be explained as lightning, etc. (2) *Reference to an Evolutionary Series.* Sometimes an object (or class of objects) is explained by assigning to it a place in a possible evolutionary series. Thus, *e.g.*, the rival explanations of the South African skull of an alleged ape-man assigned to it different places in the chain of biological evolution. (3) *Reference to Mediating Conditions.* Sometimes the problem is, how certain apparently remote or different facts or events come to be connected nevertheless. In such cases the explanation takes the form of indicating certain intermediate facts or events which bridge the gulf. Thus, *e.g.*, the perception of sound, light, etc., is explained by the mediation of air-waves or ether-waves, etc., between the source of stimulation and the percipient or receiver. (4) *Reference to Laws.* The commonest type of explanation consists in referring events to certain relevant laws. Thus, *e.g.*, the bent appearance of a stick partly immersed in water is explained by reference to Snell's law of refraction. The position of a planet may be explained by reference to Kepler's laws. And Kepler's laws themselves may be explained by reference to Newton's law of gravitation. (5) *Reference to Purpose.* In the study of human conduct, and of certain other biological phenomena, it seems impossible to dispense with all reference to purpose, even when other kinds of explanation are made use of at the same time. The most familiar way of explaining human actions is by referring them to some purpose that is pursued either consciously or unconsciously. Such explanations are suggested by our own felt experiences on similar occasions, and have always been found so satisfying to many people that they have been applied also to most other phenomena at one time or another. Hence the animism, fetishism, and anthropomorphism characteristic of the early history of human thought. This kind of extravagance was a serious obstacle to the progress of science during many centuries—to say nothing about the evil influences of theological anthropomorphism. Hence the reaction in modern science, which has not unnaturally displayed a strong hostility to all such teleological explanations, that is, explanations by reference to purposes. But the just revolt against one extreme does not justify another extreme. Such teleological explanations, too, have their proper place in certain limited fields of research. And it seems difficult to conceive how even the most violent opponent of teleological explanation could regard his own researches, writings and other higher activities as aimless and purposeless.

What has just been said may help to account for the tendency of modern science to disclaim all attempts to *explain* things, and to confine itself to the more modest task of *describing* them. The contrast is usually expressed by the statement that science only tries to answer *how* things happen, not *why*. But to say *how* things happen is also to explain them. Indeed, what is called scientific description often includes much that cannot be considered to be anything but explanation, right or wrong. The opposition to the question: *Why?* and the identification of all explanation with answers to such questions, betrays what is really at the back of the mind of the opponents of explanation as a legitimate aim of science. They really object to teleological explanation being applied indiscriminately to all kinds of natural phenomena. This is quite right. But it is a very short-sighted policy to give this extremely narrow meaning to the term "explanation," and so to deprive science of its legitimate and honourable claim to explain things, even if it does not explain everything, nor any one thing completely. The unsophisticated man of science who is not addicted to shibboleths certainly thinks not only that science explains things, but explains them most correctly. (*See* articles INDUCTION, LOGIC, EXPLANATION, PROBABILITY, LOGIC, HISTORY OF.)

SCILLITAN MARTYRS, a company of early North African Christians who suffered under Marcus Aurelius in A.D. 180, and whose *Acta* are at once the earliest documents of the Church of Africa and the earliest specimen of Christian Latin. The martyrs take their name from Scilla (or Scillium), a town in Numidia. Their trial and execution took place in Carthage under the Proconsul Vigellius Saturninus, whom Tertullian declares to have been the first persecutor of the Christians in Africa. The date of their martyrdom is the 17th of July A.D. 180. We have in this martyrdom an excellent example of "Acts of Martyrs" properly so called. The document is in brief legal form, beginning with the date and the names of the accused, and giving the actual dialogue between them and their judge. It closes with the sentence, based on "obstinate" persistency in an illicit cult, and with the proclamation by the herald of the names of the offenders and the penalty. All this may quite well be a transcript of the *Acta,* or official report of the proceedings.

The Scillitan sufferers were twelve in all—seven men and five women. Two of these bear Punic names, but the rest Latin names. Six had already been tried: of the remainder, to whom these *Acta* primarily relate, Speratus is the principal spokesman. He claims for himself and his companions that they have lived a quiet and moral life, paying their dues and doing no wrong to their neighbours. But when called upon to swear by the genius of the emperor, he replies: "I recognize not the empire of this world; but rather do I serve that God whom no man hath seen, nor with these eyes can see."

BIBLIOGRAPHY.—The historical questions connected with these martyrs are treated by Lightfoot, *Ignatius* (1889, 2nd ed.), i. 524 ff. The Latin text, together with later recensions and a Greek version, is published in *Texts and Studies,* i. 2 (Passion of Perpetua, 1890); *see* also *Analecta Bollandiana* (1889), viii. 5; H. M. Gwatkin, *Selections from Early Christian Writers,* where, as in *Ante-Nicene Fathers,* ix. 285, there is an English translation.

SCILLY ISLES, group of small islands, off Cornwall, England, 25 m. W. by S. of Land's End. They form an outlying member of the series of granite masses of Cornwall and contain a few metalliferous veins. The origin of their name has never been authoritatively settled. The islands are wild and picturesque, with sheer cliffs and many large caves hollowed out by the Atlantic. Owing to the reefs and shoals by which these shores are surrounded, navigation becomes perilous in rough weather. In 1707 Sir Cloudesley Shovel perished here and a local proverb tells that for every man who dies a natural death on the islands the sea takes nine. On an outlying rock to the south-west is Bishop Light (49° 52′ 30″ N., 6° 27′ W.), constructed with infinite difficulty in 1858, and rebuilt 30 years later, and other lighthouses are on Round island and Penninis head (St. Mary's).

The islands are composed of granite, most of which is coarse and porphyritic, but the centre of the mass is finer and non-porphyritic. The finer granite occurs on the north-west side of St. Mary's, the southern part of Tresco, Bryher and Samson and the north-west side of Annet. Elvans (dykes) of quartz-porphyry are found in the granite. On the north-east end of White island a fragment of the altered killas (shale), which once covered the whole area, is still visible. A gravel deposit with chalk flints and Greensand cherts which caps some of the higher ground

on St. Mary's may possibly be of Eocene age. Raised beach, blown sand, fragmental granitic waste and an iron-cemented glacial deposit are found resting upon the granite.

The climate of the islands is unusually mild, snow being rarely seen, and the range of temperature being from 46° to 58° F. Fuchsias, geraniums and myrtles attain an immense size, and aloes, cactus and prickly pear flourish in the open. The gardens of the governor on Tresco island are quite subtropical in character, and, therefore, unique in the British isles. Great flocks of sea-birds haunt the remoter parts, and on some of the islands there are deer. Some of the rarer land-birds occasionally visit the islands, such as the golden oriole.

The islands are served by steamers from Penzance, and telephone and telegraph communication is established with the mainland. The raising of early asparagus, spring vegetables and flowers is the principal industry. There is also a small coasting trade; and fishing is carried on, lobsters being sent to London.

The true islands number about 40, with total area of 4,041 ac.; but only five islands are inhabited—St. Mary's, Tresco, St. Martin's, St. Agnes and Bryher. The total population in 1931 was 1,732. Hugh Town in St. Mary's is the capital, occupying a sandy peninsula crowned by the height known as the Garrison, with Star castle, dating from the days of Elizabeth. The town possesses a harbour, and a roadstead where large vessels can lie at anchor. Governed by a county council, they are part of the St. Ives parliamentary division, Cornwall.

On Tresco there are ruins of an abbey, and of two fortifications called Oliver Cromwell's tower and King Charles's tower. The church of St. Nicholas was built in 1882. Numerous rude pillars and circles of stones are to be noticed; and barrows are common, the most remarkable of these prehistoric remains being a barrow on the Isle of Samson, 58 ft. in girth, and containing a very perfect "kistvaen," or sepulchral chamber of stone.

It is not until the reign of Henry I. that we have written evidence concerning these isles. The king gave all the churches of Scilly and the land to the abbot and church of Tavistock. In 1180 the bishop of Exeter confirmed a grant by Richard de Wicha. Secular priests were temporally substituted for regulars by the abbot of Tavistock in 1345. The family of Blanchminster (de Albo Monasterio), at the beginning of the 14th century, held of the earldom of Cornwall lands in Scilly at a yearly service of 6s. 8d. or 600 puffins. The Blanchminsters resisted and imprisoned the coroner of Cornwall and in 1319 were granted a coroner of their own. In 1345 they are found petitioning the king against an invasion of the king's Welsh troops, who, being becalmed at Scilly, had carried away everything. In 1547 Silvester Danvers, as representing the Blanchminsters, sold his moiety of Scilly to Sir Thomas Seymour, by whose attainder in 1549 this and probably the other moiety fell to the Crown. The suppression of the religious houses had already placed church land and revenues at the king's disposal. During the Civil Wars, Hugh Town in 1645 gave shelter to Prince Charles, until his escape to Jersey. In 1649 the islands were occupied by a royalist, Sir Richard Grenville, who swept the surrounding seas for two years, before Admiral Blake and Sir John Ayscue forced him to surrender. In ancient times a haunt of pirates, the islands were afterwards notorious for smuggling. In 1687 the whole of Scilly was granted to Sidney Godolphin for 89 years from the expiration of the lease for 50 years granted to Francis Godolphin in 1636 by Charles I. In 1831 Augustus Smith succeeded the Godolphins as lessee.

SCIPIO ("staff"; the first *i* is long—Scīpio), the name of a patrician branch of the Cornelian gens whose historical representatives are separately noticed.

SCIPIO, PUBLIUS CORNELIUS, father of the elder Africanus. He was consul in 218 B.C., the first year of the Second Punic War, and sailed with an army from Pisa to Massilia, with the view of arresting Hannibal's advance on Italy. Failing to meet him, he returned by sea to Cisalpine Gaul, having sent back his army to Spain under the command of his brother Gnaeus, with instructions to hold the Carthaginian forces there in check. On his return to Italy he at once advanced to meet Hannibal. In a cavalry engagement in the upper valley of the Po, on the Ticinus, he was defeated and severely wounded. Again, in December of the same year, he witnessed the complete defeat of the Roman army on the Trebia, his colleague, T. Sempronius Longus, having insisted on fighting contrary to his advice. His term of command was extended, and we find him with his brother in Spain in the following year, winning victories over the Carthaginians and strengthening Rome's hold on that country, till 212 (or 211). The details of these campaigns are not accurately known, but it would seem that the ultimate defeat and death of the Scipios were due to the desertion of the Celtiberi, bribed by Hasdrubal, Hannibal's brother.

See Polybius iii. 40; Livy xxi.–xxv.; Appian, *Hannib.* 5–8, *Hisp.* 14–16.

SCIPIO AEMILIANUS AFRICANUS, PUBLIUS CORNELIUS, the younger (185–129 B.C.), was the younger son of L. Aemilius Paullus, the conqueror of Macedonia. He fought when a youth of 17 by his father's side at the battle of Pydna (168), which decided the fate of Macedonia and made northern Greece subject to Rome. He was adopted by P. Cornelius Scipio, the eldest son of Scipio Africanus the elder, and from him took the name Scipio. In 151, a time of defeat and disaster for the Romans in Spain, he voluntarily offered his services in that country and obtained an influence over the native tribes similar to that which the elder Scipio, his grandfather by adoption, had acquired nearly 60 years before. In the next year an appeal was made to him by the Carthaginians to act as arbiter between them and the Numidian prince Massinissa, who, backed up by a party at Rome, was incessantly encroaching on Carthaginian territory. In 149 war was declared by Rome, and a force sent to besiege Carthage.

In the early operations of the war, which went altogether against the Romans, Scipio, though a subordinate officer, distinguished himself repeatedly, and in 147 he was elected consul, while yet under the legal age, in order that he might hold the supreme command. After a year of desperate fighting and splendid heroism on the part of the defenders he carried the fortress, and at the senate's bidding levelled it to the ground. On his return to Rome he celebrated a splendid triumph, having established a personal claim to the surname of Africanus. In 142, during his censorship, he endeavoured to check the growing luxury and immorality of the period. In 139 he was unsuccessfully accused of high treason by Tiberius Claudius Asellus, whom he had degraded when censor. The speeches delivered by him on that occasion (now lost) were considered brilliant. In 134 he was again consul, with the province of Spain, where a demoralized Roman army was vainly attempting the conquest of Numantia on the Durius (Douro). After devoting several months to restoring the discipline of his troops, he reduced the city by blockade. The fall of Numantia in 133 established the Roman dominion in the province of Hither Spain. For his services Scipio received the additional surname of Numantinus.

Scipio himself, though not in sympathy with the extreme conservative party, was decidedly opposed to the schemes of the Gracchi (whose sister Sempronia was his wife). When he heard of the death of Tiberius Gracchus, he is said to have quoted the line from the *Odyssey* (i. 47), "So perish all who do the like again"; on his return to Rome he wrecked the working of the Gracchan agrarian legislation by getting the commissioners' judicial powers removed. This made him the chief enemy of the popular party for the time, and he died mysteriously in 129, the night before he was to have spoken on the agrarian laws. The mystery of his death was never cleared up, and there were political reasons for letting the matter drop, but there is little doubt that he was assassinated by one of the supporters of the Gracchi, probably Carbo.

He was a man of culture and refinement; he gathered round him such men as the Greek historian Polybius, the philosopher Panaetius, and the poets Lucilius and Terence. At the same time he had all the virtues of an old-fashioned Roman, according to Polybius and Cicero, the latter of whom gives an appreciation of him in his *De republica*, in which Scipio is the chief speaker. As a speaker he seems to have been no less distinguished than as a soldier. Though politically opposed to the Gracchi, he cannot be said to have been a foe to the interests of the people, but their revolutionary methods drove him into the arms of the Senatorial party, who

were not much more to his taste themselves. He was, in fact, a moderate man, in favour of conciliation, and as such inevitably unpopular, though respected, in an age of political violence.

See Polybius xxxv. 4, xxxix.; Vell. Pat. i. 12; Florus ii. 15, 17, 18; Appian, *Punica*, 72, 98, 113–131, *Hisp.* 48–95, *Bell. Civ.* i. 19; Plutarch, *Aemilius Paullus*, 22, *Tib. Gracchus*, 21, *C. Gracchus*, 10; Gellius iv. 20, v. 19; Cicero, *De orat.* ii. 40; exhaustive life by E. Person (Paris, 1877); monograph by Lincke (Dresden, 1898).

SCIPIO AFRICANUS, PUBLIUS CORNELIUS, the elder (237–183 B.C.), son of P. Cornelius Scipio; was present at the disastrous battles of the Ticinus (where, according to one tradition, he saved his father's life), the Trebia and Cannae. Even after the last he resolutely protested against several Roman nobles who advocated leaving Italy. The year after his father's death, he was elected to the command of the new army which the Romans resolved to send to Spain. All Spain south of the Ebro in the year of his arrival (210 or 209) was under Carthaginian control, but fortunately for him the three Carthaginian generals, Hasdrubal and Mago (Hannibal's brothers), and Hasdrubal the son of Gisgo, were not disposed to act in concert and were preoccupied with revolts in Africa. Scipio, on landing at the mouth of the Ebro, was thus enabled to surprise and capture New Carthage, the headquarters of the Carthaginian power in Spain. He thus obtained a rich booty of war stores and supplies, and an excellent harbour. His kindly treatment of the Spanish hostages and prisoners brought many over to his side. In 209 he drove back Hasdrubal, from his position at Baecula, on the upper Guadalquivir, but was unable to hinder his march to Italy. After winning over a number of Spanish chiefs he achieved in 206 a decisive victory at Ilipa (near Corduba), which resulted in the evacuation of Spain by the Punic commanders. With the idea of striking a blow at Carthage in Africa, he paid a short visit to the Numidian princes, Syphax and Massinissa, but at the court of Syphax he was foiled by the presence of Hasdrubal, the son of Gisgo, whose daughter Sophonisba was married to the Numidian chief. On his return to Spain Scipio had to quell a mutiny among his troops. Hannibal's brother Mago had meanwhile sailed for Italy, and in 206 Scipio himself, having secured the Roman occupation of Spain by the capture of Gades, gave up his command and returned to Rome. In the following year he was elected consul, the province of Sicily being assigned to him. Hannibal was by now penned in the south-west of Italy, and Scipio was strongly in favour of carrying the war into Africa. Here he was strongly opposed by the old Roman nobility, with whom he was unpopular. After a commission of enquiry had visited Sicily, he sailed in 204 and landed near Utica. Carthage meanwhile had secured the friendship of the Numidian Syphax, whose advance compelled Scipio to raise the siege of Utica and to entrench himself on the shore between that place and Carthage. Next year he destroyed two combined armies of the Carthaginians and Numidians. After the failure of peace negotiations in which Scipio displayed great moderation, he defeated Hannibal in a decisive battle near Zama (Oct. 19, 202; *see* PUNIC WARS). In the subsequent settlement with Carthage he upheld with success his comparatively lenient terms against the immoderate demands of many Roman aristocrats.

Scipio was welcomed back to Rome with the surname of Africanus, and had the good sense to refuse the many honours which the people would have thrust upon him. For some years he lived quietly and took no part in politics. In 193 he was one of the commissioners sent to Africa to settle a dispute between Massinissa and the Carthaginians. In 190, when the Romans declared war against Antiochus III. of Syria, Publius was attached as legate to his brother Lucius, to whom the chief command had been entrusted. The two brothers brought the war to a conclusion by a decisive victory at Magnesia in the same year. Meanwhile Scipio's political enemies had gained ground, and on their return to Rome a prosecution was started (187) by two tribunes against Lucius on the ground of misappropriation of moneys received from Antiochus. As Lucius was in the act of producing his account-books his brother wrested them from his hands, tore them in pieces, and flung them on the floor of the senate-house. This created a bad impression; Lucius was brought to trial, condemned and heavily fined. Africanus himself was subsequently (185) accused of having been bribed by Antiochus, but by reminding the people that it was the anniversary of his victory at Zama he caused an outburst of enthusiasm in his favour. The people crowded round him and followed him to the Capitol to offer thanks to the gods and beg them to give Rome more citizens like himself. He then retired to his native country seat at Liternum on the coast of Campania, where he died. By his wife Aemilia, daughter of the Aemilius Paullus who fell at Cannae, he had a daughter Cornelia, who became the mother of the two famous Gracchi.

Scipio was one of Rome's greatest generals. Skilful alike in strategy and in tactics, he had also the faculty of inspiring his soldiers with confidence. According to the story, Hannibal, who regarded Alexander as the first and Pyrrhus as the second among military commanders, confessed that had he beaten Scipio he should have put himself before either of them. He was a man of great intellectual culture and could speak and write Greek perfectly. He wrote his own memoirs in Greek. He also enjoyed the reputation of being a graceful orator. There was a belief that he was a special favourite of heaven and held actual communication with the gods. It is quite possible that he himself honestly shared this belief; to his political opponents he was often harsh and arrogant, but towards others singularly gracious and sympathetic. According to Gellius, his life was written by Oppius and Hyginus, and also, it was said, by Plutarch.

See Livy xxi.–xxxviii. and Polybius; Aulus Gellius iv. 18; Val. Max. iii. 7; biography by F. D. Gerlach (1868); E. Berwick (1817), with notes and illustrations; B. H. Liddell Hart, *A Greater than Napoleon —Scipio Africanus* (1926); also PUNIC WARS.

SCIRE FACIAS, in English and American law, a judicial writ founded upon some record directing the sheriff to make it known (scire facias) to the party against whom it is brought, and requiring the latter to show cause why the party bringing the writ should not have the advantage of such record. Proceedings in *scire facias* are regarded as an action, and the defendant may plead his defence as in an action. The writ in England is now of little practical importance. In America the writ has been abolished in the code States and an ordinary action is maintainable in its stead; in other States *scire facias* retains much of its original importance.

SCISSORS: *see* CUTLERY.

SCOLECITE, a mineral of the Zeolite group (*q.v.*). It is a hydrated silicate of lime and alumina, crystallizing in the monoclinic system, with angles very near those of the cube. It commonly occurs as bundles of radiating fibres, and when heated sometimes curls up like a worm, whence the name (Gr. σκώληξ, a worm). It is usually colourless or white and more or less transparent. Scolecite occurs frequently with other zeolites in the western isles of Scotland, Iceland, and in the Deccan Trap area in India, among many other localities.

SCOLOPACIDAE: *see* SNIPE; WOODCOCK; SANDPIPER.

SCONE, a parish of Perthshire, Scotland, containing Old Scone, the site of an historic abbey and palace, and New Scone, a modern village, 2 m. N. of Perth, near the left bank of the Tay. Pop. of parish (1931) 2,559. It became the capital of Pictavia, the kingdom of northern Picts, in succession to Forteviot. The Moot Hill, where the first national council of which we possess records was held (906), was known also as the Hill of Belief from the fact that here the Pictish king promulgated the edict regulating the Christian church. The abbey was founded in 1115 by Alexander I., but long before this date Scone had been a centre of ecclesiastical activity and the seat of a monastery. Kenneth is alleged to have brought the Stone of Destiny, on which the Celtic kings were crowned, from Dunstaffnage castle on Loch Etive, and to have deposited it in Scone, whence it was conveyed to Westminster abbey (where it lies beneath the coronation chair) by Edward I. in 1296. Most of the Scottish kings were crowned at Scone, the last function being held on Jan. 1, 1651, when Charles II. received the crown. The abbey and the house of Scone were burned down by the Reformers in 1559, and next year the estates were granted to the Ruthvens. On the attainder of the family after the Gowrie conspiracy in 1600, the land passed to Sir David Murray of the Tullibardine line, who became 1st vis-

count Stormont (1621) and was the ancestor of the earl of Mansfield, to whom the existing house belongs. Sir David completed in 1606 the palace which the earl of Gowrie had begun. The present palace, which dates from 1803 and stands in a beautiful park, contains several historic relics.

SCOPAS, probably of Parian origin, the son of Aristander, a great Greek sculptor of the 4th century B.C. Although classed as an Athenian, and similar in tendency to Praxiteles, he was really a cosmopolitan artist, working largely in Asia and Peloponnesus. The extant works with which he is associated are the Mausoleum of Halicarnassus (finished 349) and the temple of Athena Alea at Tegea (some time after 395). In the case of the Mausoleum, though no doubt the sculpture generally belongs to his school, we are unable to single out any special part of it as his own. A recent suggestion attributes the small "chariot-race" frieze to Scopas. But we have good reason to think that the pedimental figures from Tegea are Scopas' own early work. The subjects of the pedimental compositions were the hunting of the Calydonian boar and the battle between Achilles and Telephus. Four heads remain, that of Hercules, that of Atalanta and two of warriors: also part of the body of Atalanta and the head of the boar. Unfortunately all these are in very poor preservation; but it is allowed that they are our best evidence for the style of Scopas.

Ancient writers give us a good deal of information as to works of Scopas. He made for the people of Elis a bronze Aphrodite, riding on a goat (copied on the coins of Elis); a Maenad at Athens, running with head thrown back, and a torn kid in her hands was ascribed to him; of this Dr. Treu has published a probable copy in the Albertinum at Dresden (*Mélanges Perrot,* p. 317). Another type of his was Apollo as leader of the Muses, singing to the lyre. The most elaborate of his works was a great group representing Poseidon, Thetis and Achilles, accompanied by Nereids, Tritons and other sea-beings. On the basis of his known work, many extant statues can be confidently attributed to his influence and some may be direct copies.

Jointly with his contemporaries Praxiteles and Lysippus, Scopas may be considered as having completely changed the character of Greek sculpture. It was they who initiated the lines of development which culminated in the schools of Pergamum, Rhodes and other great cities of later Greece. In most of the modern museums of ancient art their influence may be seen in three-fourths of the works exhibited. At the Renaissance it was especially their influence which dominated Italian painting and through it modern art.

See B. Gräf in *Röm. Mittheit.* (1889), 199; Urlichs, *Scopas* (Greifswald, 1863).

SCOPIDAE: *see* HAMMERHEAD.

SCOPOLAMINE. Scopolamine or hyoscine is a complex alkaloid closely related to atropine and having the chemical formula $C_{17}H_{21}NO_4$. It is laevorotary to polarised light but in its commercial form may be mixed with its dextrorotary isomer. Scopolamine occurs in varying proportions and is extracted from deadly nightshade, henbane, thornapple and a few other less-known plants. Hyoscine hydrobromide, the official preparation of the British Pharmacopoeia, consists of transparent colourless bitter crystals, which are soluble in water and have the formula $C_{17}H_{21}NO_4HBr_3H_2O$. The therapeutic dose is $\frac{1}{200}$ to $\frac{1}{100}$ grain.

The chief action of scopolamine is hypnotic, a condition very similar to natural sleep being induced. This usually lasts for about six hours and the patient wakes up with an unclouded mind but may complain of thirst and dryness of the mouth and throat. In some cases a stage of excitement, giddiness and incoherent speech may precede that of sleep, and it is this uncertainty of action which renders the drug somewhat unreliable. Some tolerance is produced after prolonged exhibition of scopolamine so that the dose has to be increased to have the same effect.

Administration.—Scopolamine by itself does not relieve pain, so that for anaesthetic purposes it is usually combined with morphia. Some such mixture as:—Morphine gr. $\frac{1}{6}$, Scopolamine gr. $\frac{1}{100}$, is injected hypodermically, the scopolamine being repeated as necessary in doses of gr. $\frac{1}{400}$. This "twilight sleep" method does not produce surgical anaesthesia, but has the double action of dulling pain and producing loss of memory. It is thus useful in labour, especially when the process is likely to be prolonged, as in primiparae. In these cases the initial dose should be given when the first stage is well established. The patient should then fall into a somnolent condition from which she is partially roused when each pain occurs. To obtain the best effect, the patient's ears should be plugged with cotton wool, her eyes bandaged, and the room kept perfectly quiet. The chief disadvantage in the "twilight sleep" method in labour is that the child may be born in an apnoeic condition and a considerable time may elapse before regular respiration is established. If skilled attention is available, however, it is rare for the baby to suffer any ill effects. The action of the drug upon the foetal heart appears to be negligible. If forceps have to be applied or any other form of instrumental delivery is necessary, an inhalation anaesthesia will have to be administered in addition.

"Twilight sleep" can also be used as a preliminary to the various types of regional analgesia. For instance, a severe operation can be performed under preliminary morphine-scopolamine injection and subsequent spinal analgesia without the patient being aware that he has been moved out of bed.

Some anaesthetists also use the drugs as a preliminary to general anaesthesia, such as nitrous oxide-oxygen. This method undoubtedly lessens the apprehension of a nervous patient and has the advantage that less general anaesthetic is necessary, but it tends to depress respiration so that cyanosis and a difficult administration may ensue. The breathing may become so shallow that the requisite depth of anaesthesia is impossible to attain. The blood pressure also tends to fall, while the eye and other reflex signs which are useful in estimating the depth of anaesthesia can no longer be trusted.

Scopolamine-morphine is definitely contra-indicated in children, in severe abdominal operations and in cases of intestinal obstruction, as the drugs may increase the paralysis of the gut. Furthermore, it should not be given to patients who are known to have an idiosyncrasy for either of its constituents. For these reasons, scopolamine-morphine should not be used as a routine preliminary injection but should be reserved for selected cases.

SCORDISCI, a Celtic tribe inhabiting the southern part of lower Pannonia between the Savus, Dravus and Danuvius. As early as 175 B.C. they came into collision with the Romans by assisting Perseus, King of Macedonia; and after Macedonia became a Roman province they were for many years engaged in hostilities with them. In 135 B.C. they were defeated by M. Cosconius in Thrace; in 118 B.C. Sextus Pompeius, the grandfather of the triumvir, was slain fighting against them near Stobi. In 114 B.C. they surprised and destroyed the army of Gaius Porcius Cato, but were defeated by Q. Minucius Rufus in 107. They still from time to time gave trouble to the Roman governors of Macedonia; they even advanced as far as Delphi and plundered the temple; but Lucius Cornelius Scipio Asiaticus finally overcame them in 88 B.C. and drove them across the Danube. In Strabo's time they had been expelled from the valley of the Danube by the Dacians (Strabo vii. pp. 293, 313).

SCORESBY, WILLIAM (1789–1857), English Arctic explorer, scientist and divine, was born near Whitby, Yorkshire, on Oct. 5, 1789. He made his first voyage with his father when he was eleven years of age, but on his return he was sent back to school till 1803. After this he was his father's constant companion, and was with him on May 25, 1806, on the whaler "Resolution," when he reached 81° 30′ N. lat. (19° E. long.). In 1811 his father resigned to him the command of the "Resolution." In his voyage of 1813 he established the fact that the temperature of the polar ocean is warmer at great depths than at the surface. In 1819 he was elected a fellow of the Royal Society of Edinburgh. In his voyage of 1822 to Greenland he surveyed and charted 400 m. of the east coast, between 69° 30′ and 72° 30′. This, however, was the last of his Arctic voyages. On his return

his wife had died, and he entered the church. After two years at Cambridge he took his degree (1825) and was appointed to the curacy of Bassingby, Yorkshire, later to preferments at Liverpool, at Exeter and Bradford. In 1824 he was elected F.R.S., and he received other honours. From the first he was an active member and official of the British Association, and he contributed especially to the knowledge of terrestrial magnetism. In order to obtain additional data for his theories on magnetism he made a voyage to Australia in 1856, the results of which were published in a posthumous work—*Journal of a Voyage to Australia for Magnetical Research,* edited by Archibald Smith (1859). He visited America in 1844 and 1848. He died at Torquay on March 21, 1857.

He wrote: *An Account of the Arctic Regions and Northern Whale Fishery* (1820) and *Journal of a Voyage to the Northern Whale Fishery, including Researches and Discoveries on the Eastern Coast of Greenland* (1823).

See also the *Life* by his nephew, R. E. Scoresby-Jackson (1861).

SCORIA, in geology, a name applied to lava when moderately vesicular and having a structure like that of a clinker (Lat. *scoria,* slag). Ejected masses of scoriaceous lava are often called "cinders," a term conveniently used for all lumps of vesicular lava. (*See* VOLCANO.)

SCORPIO or **SCORPIUS** ("The Scorpion"), in astronomy, the 8th sign of the zodiac (*q.v.*), denoted by the symbol ♏. The Greeks fabled that Orion having boasted to Diana and Latona that he would kill every animal on the earth, these goddesses sent a poisonous reptile—a scorpion—which stung him so that he died. Jupiter raised the scorpion to Heaven, and afterwards, at Diana's request, did the same for Orion. Not much of the constellation can be seen from the latitude of Britain, but in the southern hemisphere it is a particularly fine constellation, the resemblance to a scorpion being well-marked. The brightest star is Antares, of a noticeably red colour.

SCORPION, the name for the order Scorpiones of the Arachnida (*q.v.*), distinguished by having the last five segments of the body modified to form a flexible tail, armed with a sting consisting of a vesicle holding a pair of poison glands, and of a sharp spine behind the tip of which the ducts of the glands open. In addition, they have four pairs of walking legs; the second pair form powerful pincers, and those of the first pair smaller nippers. They feed principally upon insects although the larger kinds may kill small lizards and mice. The large pincers are studded with tactile hairs, and the moment an insect touches these he is seized by the pincers, the scorpion's tail brought over his back and the sting thrust into the prey. Scorpions vary in size from about 1 in. to 8 in. The poison is more virulent in some of the smaller than in the larger species. Upon mankind the effects of the poison are seldom fatal.

The belief that scorpions commit suicide by stinging themselves to death when tortured by fire is quite without foundation; the venom has no effect upon the individual itself, nor upon other members of the same species. Scorpions, however, succumb rapidly when exposed to the warmth of a fire or of the tropical sun. They are easily rendered innocuous by scraping off the sharp point of the sting; and it has been shown that immunity to the ill effects can be acquired by being repeatedly stung.

Many scorpions exhibit a conspicuous warning coloration of jet-black or black and yellow; and many have stridulating organs. These, like the rattle of rattlesnakes, advertise their presence and help to prevent their being attacked or trodden on. In habits they are nocturnal, spending the daytime concealed under stones or fallen tree trunks or in burrows. Amongst the burrowing kinds are the large African species of the genera *Pandinus* and *Opisthophthalmus* and the eastern genus *Palamnaeus.*

Scorpions are viviparous. The brood, which consists of a dozen or more young, is carried about on its mother's back until they are able to shift for themselves. The young resemble their parents and undergo no metamorphosis. Moulting occurs by means of a split just below the edge of the carapace as in king-crabs and spiders.

Scorpions were already in existence in the Carboniferous Period and there is no essential structural difference between these fossils and existing forms. These Carboniferous scorpions, however, were preceded by others, in Silurian deposits, which lived in the sea and exhibit differences marking them off as a distinct group and attesting affinity with the earlier marine Arachnida, known as Gigantostraca. Their legs were short, thick, and ended in a single claw, adapted for maintaining a hold upon rocks or seaweed against the wash of waves. These Silurian scorpions, of which the best-known genus is *Palaeophonus,* were only 1 or 2 in. in length.

At the present time scorpions are almost universal south of the 40th or 45th parallels of north latitude; and their geographical distribution shows a close correspondence with that of the mammalia, their absence from New Zealand being an interesting point of agreement. Scorpions are adapted to diverse conditions, some thriving in tropical forests, others on open plains, others in sandy deserts, and a few at high altitudes with abundant snow in winter. In the tropics they aestivate at times of drought; and in temperate latitudes they pass the cold months in hibernation.

SCORPION-FLY, the name given to insects of the family *Panorpidae* of the order Mecoptera. Their name is derived from the fact that the males carry the extremity of the body upwardly curved after the manner of a scorpion. These insects are recognizable by the beak-like prolongation of the front of the head and the two pairs of usually conspicuously marbled wings. The chief genus is *Panorpa,* which is widely distributed, three species occurring in the British Isles. Both the larvae and perfect insects are carnivorous: the former are caterpillar-like; they live in the earth and are provided with eight pairs of abdominal feet in addition to three pairs of short thoracic legs. The pupa is found in an earthen cavity below ground and the perfect insects occur among rank herbage in shaded situations.

SCORZONERA (*Scorzonera hispanica*), a hardy perennial, native to central and southern Europe, and cultivated in gardens as a vegetable for its fleshy cylindrical roots, which resemble those of salsify except in being black outside. They should be treated in every respect like salsify. The genus is a member of the family Compositae, and nearly allied to *Tragopogon,* to which salsify belongs.

SCOT, MICHAEL (? 1175–*c.* 1232), Scottish translator, mathematician and astrologer. He studied at Oxford and Paris, and after being ordained, held various benefices in Italy, but refused the appointment of archbishop of Cashel in Ireland. Having acquired a knowledge of Arabic at Toledo, he became one of the scholars of the court of Frederick II., and at the instigation of the emperor superintended (along with Hermannus Alemannus) a fresh translation of Aristotle and the Arabian commentaries from Arabic into Latin. The chief of these were the *De Animalibus,* the *De anima,* the *De coelo,* and probably the *Physics* and the *Metaphysics,* and also the *De Sphaera* of Al Bitrogi. Scot's own books, dealing almost exclusively with astrology, alchemy and the occult sciences generally, are mainly responsible for the development of the Michael Scot legend. Chief among these are *Super auctorem spherae* (pr. Bologna 1495, Venice 1631); *De sole et luna* (pr. Strassburg 1622), the *De chiromantia,* an opuscule often published in the 15th century; *De physiognomia et de hominis procreatione* (18 editions between 1477 and 1660).

Around his own death many legends gathered. He was supposed to have foretold that he would end by a blow from a stone of not more than two ounces in weight, and that to protect himself he wore an iron helmet, and that, raising this in church at the elevation of the host, the fatal stone fell on him from the roof. Italian tradition says he died in Italy; other accounts place his death in his native country, and his burial at Holme Cultram in Cumberland or in Melrose Abbey. In the notes to Scott's *Lay of the Last Minstrel,* of which the opening of the wizard's tomb forms the most striking episode, Scott recounts the exploits attributed by popular belief to the magician. "In the south of Scotland any work of great labour and antiquity is ascribed either to the agency of Auld Michael, of Sir William Wallace or the devil." He used to feast his friends with dishes brought by spirits from the royal kitchens of France and Spain and other lands. On an embassy to France he brought the French monarch to his knees by the stamp-

ing of his horse's hoof, the first ringing the bells of Notre Dame and the second causing the towers of the palace to fall. Other powers and exploits are narrated in Folengo's Macaronic poem of *Merlin Coccaius* (1595). Michael's reputation as a magician was early established. He appears in the *Inferno* of Dante (canto xx. 115–117) among the magicians and soothsayers. He is represented in the same character by Boccaccio.

See J. Wood Brown, *Life and Legend of Michael Scot* (1897); P. Duhem, *Le Système du Monde* t. III. (1917); C. Haskens, "Michael Scot and Frederick II." in *Isis* (1921) and *Studies in the Hist. of Mediaeval Science* (Cambridge, 1924); L. Thorndike, *Hist. of Magic and Experimental Science* (vol. 2, 1924).

SCOT AND LOT, a phrase common in the records of English mediaeval boroughs, applied to those householders who were assessed to any payment (such as tallage, aid, etc.) made by the borough for local or national purposes. They were usually members of a gild merchant. Previous to the Reform Act 1832 those who paid scot and bore lot were entitled to the franchise in virtue of this payment.

SCOTER (*Oidemia nigra*), a diving duck, also known as the "black duck" from the male being, save for a stripe of orange down the bill, wholly of that colour. Of all ducks the scoter has the most marine habits, keeping to the sea in all weathers, and coming to land only to breed. A second species, the velvet scoter, *O. fusca,* of larger size, with a white spot under each eye and a white bar on each wing, is less abundant. It has its American counterpart, *O. americana,* and a third, the surf-duck, *O. perspicillata,* with a white patch on the crown and another on the nape, and a curiously parti-coloured bill, is not uncommon in North American waters. All the species have their true home in arctic or sub-arctic countries, but the scoter itself breeds occasionally in Scotland. The nest is on the ground and contains five to eight creamy eggs. The females are soot-coloured above and brownish white beneath. The flesh of all these birds has an exceedingly strong taste, and ranked as fish in ecclesiastical dietary.

SCOTIA, a residential village of Schenectady county, New York, U.S.A., on the north bank of the Mohawk river, opposite Schenectady; served by the Boston and Maine railroad. Pop. 1930, 7,437. It was incorporated in 1904.

SCOTLAND, that portion of Great Britain which lies north of the English boundary; it also comprises the Outer and Inner Hebrides and other islands off the west coast, and the Orkney and Shetland islands off the north coast. With England lying to the south, it is bounded on the north and west by the Atlantic ocean and on the east by the North sea. It is separated from England by the Solway firth, the Sark, Scotsdyke (an old embankment connecting the Sark with the Esk), the Esk (for one mile), the Liddel, the Kershope, the Cheviot hills, the Tweed and a small area known as the "liberties" of Berwick. The greatest length from Cape Wrath in Sutherland to the Mull of Galloway is 274 m., and the greatest breadth from Buchan Ness to Applecross in the shire of Ross and Cromarty 154 m., but from Bonar Bridge at the head of Dornoch firth to the head of Loch Broom it is only 26 m. wide, and 30 m. from Grangemouth on the Forth to Bowling on the Clyde. The coast-line is estimated at 2,300 m., the arms of the sea being so numerous and in several cases penetrating so far inland that few places are beyond 40 m. from salt water. The total area is 19,069,500 ac. or 29,796 sq.m., exclusive of inland waters (about 608 sq.m.), the foreshore (about 498 sq.m.) and tidal water (about 608 sq. miles).

The name Scotland (the ancient *Caledonia*—a name still poetically used) originated in the 11th century, when (from the tribe of Scots) part of it was called Scotia (a name previously applied to what is now Ireland); and the name of Scotland became established in the 12th and 13th centuries.

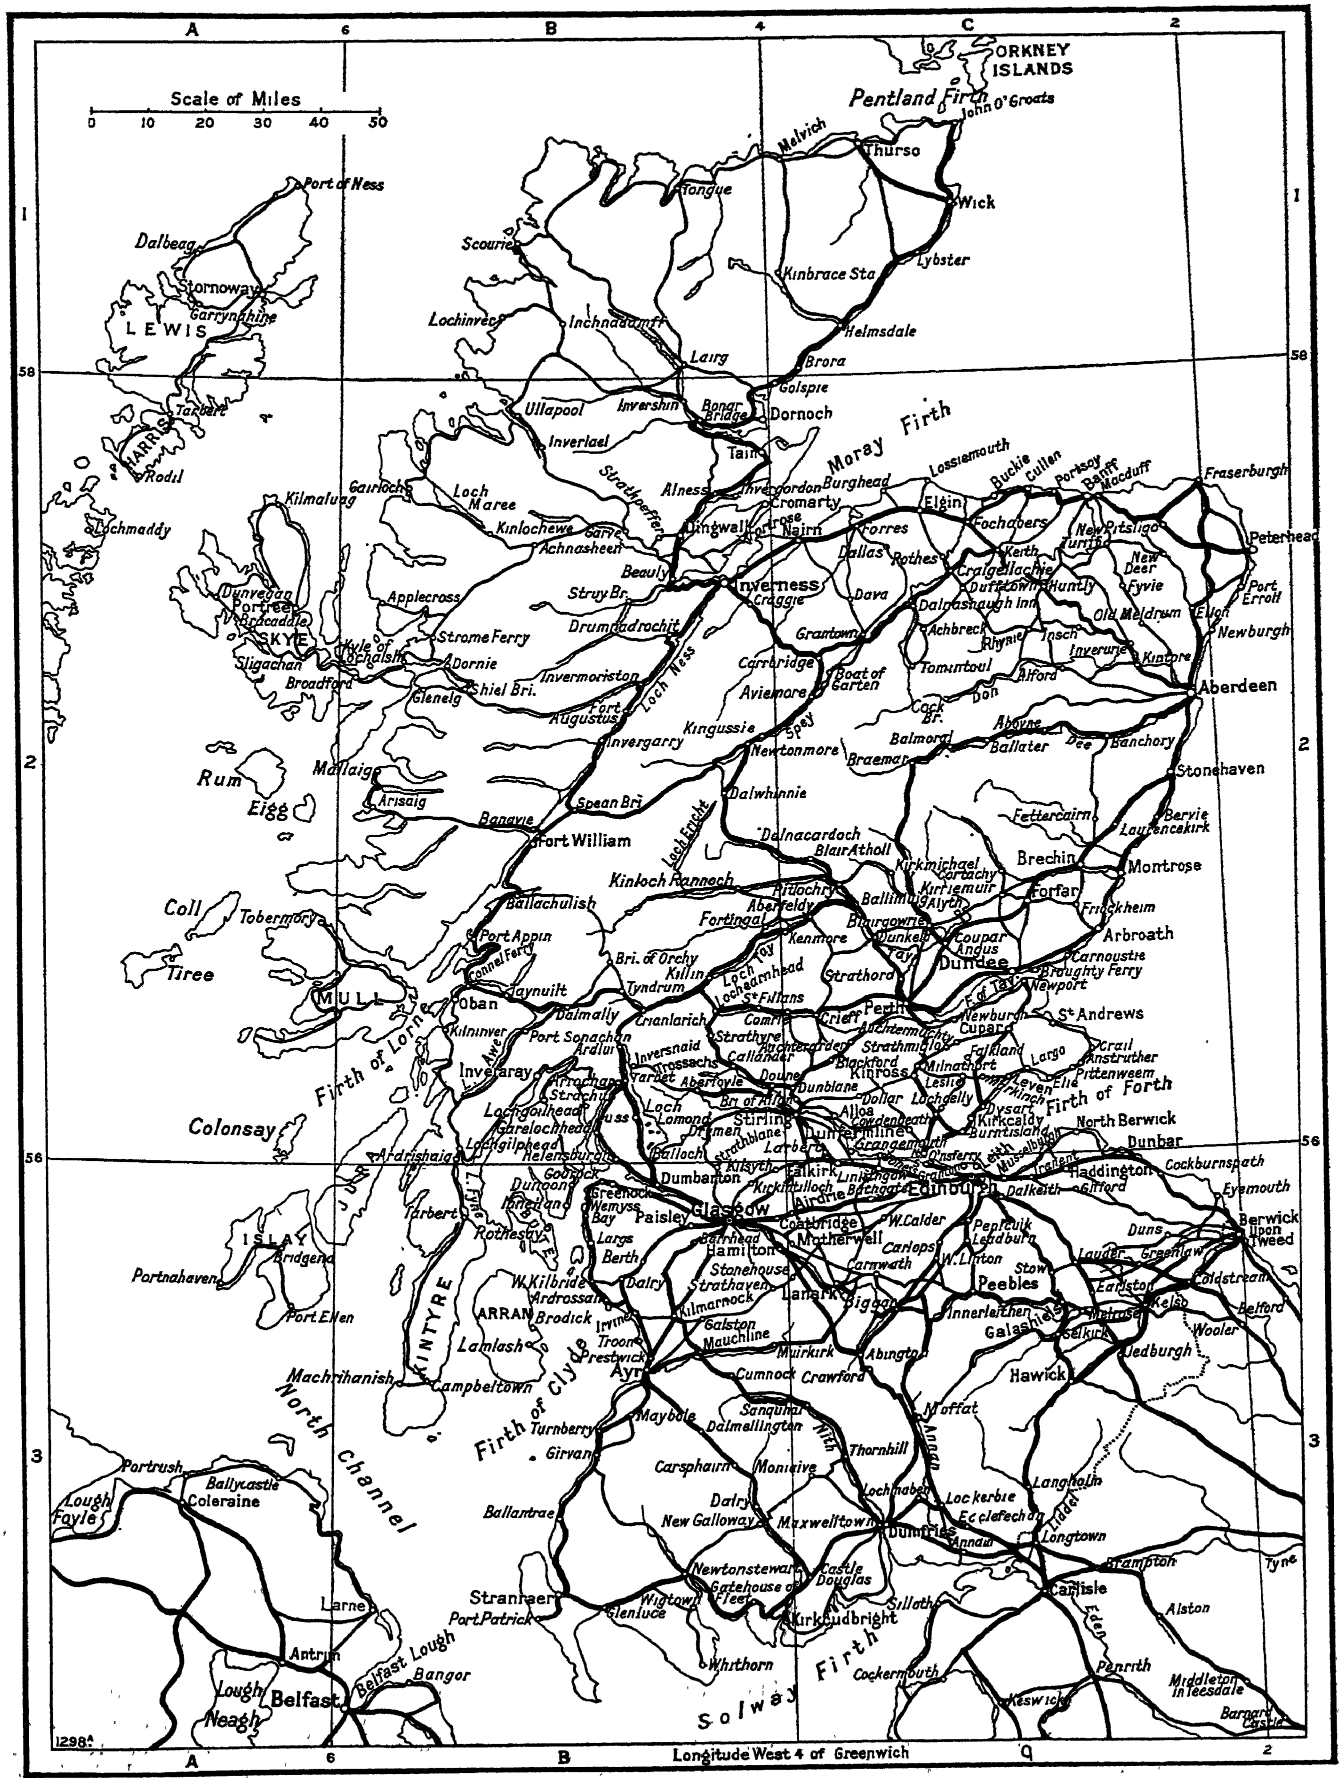
PHYSICAL GEOGRAPHY

Physically, Scotland is divided into three structural regions—the Highlands (subdivided by Glen More into the north-western and south-eastern Highlands); the central Lowlands (a tract of south-westerly to north-easterly trend, between a line drawn roughly from Girvan to Dunbar and a line drawn from Dumbarton to Stonehaven); and the southern Uplands. To these, geographers add a fourth division, to be regarded as at least a sub-region of the Highlands, viz., the lower eastern slopes of that region bordering the North sea, from Stonehaven and Aberdeen in the south to the high plain of Caithness in the north. It may be termed the north-eastern region.

The Highlands.—Nearly all this region is high ground, deeply trenched with valleys and sea lochs. The Highland hills stand in a succession of more or less parallel confluent ridges, having in the main a trend from north-east to south-west. These ridges are separated by longitudinal and furrowed by transverse valleys. The longitudinal valleys, which run in the same general direction as the ridges, have had their trend defined by geological structure, such as a line of dislocation (the Great Glen), or the plications of the rocks (Lochs Ericht, Tay and Awe, and most of the sea lochs of Argyllshire). The transverse valleys run north-west or south-east and are for the most part independent of geological structure. The valley of the Garry and Tay crosses the strike of all the Highland rocks, traverses the great fault on the Highland border, and finally breaks through the chain of the Sidlaw hills at Perth. River-gorges are characteristic features in many of the valleys. In the Old Red Sandstone they are particularly prominent where that formation has lain in the way of the streams sweeping down from the Highlands. In the basin of the Moray firth some fine examples may be seen on the Nairn and Findhorn, while on the west side of the Cromarty firth some of the small streams descending from the high grounds of the east of the shire of Ross and Cromarty have cut out defiles in the conglomerates, remarkable for their depth and narrowness. Towards the south margin of the Highlands instances of true canyons in the Old Red sandstone are to be seen where the Isla and North Esk enter that formation.

While many of the Highland mountains, viewed from near at hand, tower above the surrounding country, and are often of noble form, from a distance they are seen not to vary much from a general uniformity of height. A few exceptions occur along the western seaboard of Sutherland, in Skye, and elsewhere, but their structure explains the reason of their prominence. Regarded broadly, the Highland mountains are monuments of erosion, the relics of an old plateau, the surface and former slopes of which are shown approximately by the summits of the existing masses and the directions of the chief waterflows. The surface is rugged. The rocks project in bosses and crags, which roughen the sides and crests of the ridges. The shape and colour of these roughnesses depend on the nature of the underlying rock. Where it is hard and jointed, weathering into large quadrangular blocks, the hills are distinguished for the gnarled bossy character of their declivities, as may be seen in Ben Ledi and the heights to the north-east of it. Where, on the other hand, the rock decays into smaller debris, the hills assume smoother contours, as in the slate hills running from the Kyles of Bute to Loch Lomond.

The process by which the ancient plateau has been trenched into valleys and confluent ridges is best displayed among the higher mountains, where erosion proceeds at an accelerated pace. The long screes or talus-slopes at the foot of every crag and cliff bear witness to the continual waste. The headwaters of a river cut into the slopes of the parent hill. Each valley is consequently lengthened at the expense of the mountain from which it descends. Where a number of small torrents converge in a steep mountain recess, they cut out a crescent-shaped hollow or half-cauldron, which in the Scottish Highlands is known as a *corrie*. Usually the upper part of a corrie is formed by a crescent of naked rock, from which long trails of debris descend to the bottom of the hollow. Every distinct variety of rock has its own type of corrie, the peculiarities being marked both in the details of the upper cliffs and crags, and in the amount, form and colour of the screes. The Scottish corries have been occupied by glaciers. Hence their bottoms are generally ice-worn or strewn over with moraine stuff. Often a small tarn fills up the bottom, ponded back by a moraine. It is in such localities that we can best observe the evidences of the glaciers that once overspread the country. Among these high grounds also the gradual narrowing of ridges into sharp, narrow, knife-edged crests and the lowering of these into *cols* or passes



MAP OF THE MAIN ROADS OF SCOTLAND

can be well seen. The stages in this demolition are clearest where the underlying rock is of granite or similarly tough material, which at the same time is apt to be split and splintered by means of its numerous transverse joints. The granite mountains of Arran furnish excellent illustrations.

Where a rock yields to weather with considerable uniformity in all directions it is likely to assume conical forms in the progress of denudation. Sometimes this uniformity is attained by a general disintegration of the rock into fine debris, which rolls down the slopes in long screes. In other cases it is secured by the intersection of joints, whereby a rock, in itself hard and durable, is divided into small angular blocks, which are separated by weathering and slide down the declivities. In many instances the beginning of the formation of a cone may be detected on ridges which have been deeply trenched by valleys. The mountain Schiehallion (3,547 ft.) is an instance of a cone not yet freed from its parent ridge. A further stage in denudation results in isolated groups of cones completely separated from the rest of the rocks among which they once lay buried. Such groups may be carved out of a continuous band of rock extending into the regions beyond. The Paps of Jura, for instance, rise out of a long belt of quartzite which stretches through the islands of Islay, Jura and Scarba. In many cases, however, the groups point to the existence of some boss of rock of greater durability than those in the immediate neighbourhood, as in the Coolins (Cuchullins), and Red hills of Skye and the group of granite cones of Ben Loyal, Sutherland. The most impressive form of solitary cone is that wherein, after vast denudation, a thick overlying formation has been reduced to a single outlier, such as Morven in Caithness, the two Bens Griam in Sutherland, and the pyramids of red sandstone on the western margin of the shires of Sutherland and Ross and Cromarty. While, in Scotland, the dislocation of rocks has generally prevented the formation of continuous escarpments, there are instances of these in the wide basalt plateaux of the inner Hebrides, where lava has been poured out in nearly horizontal sheets, with occasional layers of tuff or other softer rock between them.

Erosion.—Platforms of erosion, successively established by the wearing down of the land to sea-level, occur both in the Highlands and among the southern Uplands. Allusion has been made to the flat-topped moorlands which, in the eastern Grampians, reach heights of 3,000 to 4,000ft. above the sea. The summits of Lochnagar and Ben Macdhui may be taken as examples. These mountains lie within granite areas; but not less striking examples may be found among the schists. That these high plateaux are planes of erosion is shown by their independence of geological structure, the upturned edges of the vertical and contorted schists having been shorn off and the granite wasted and levelled along its exposed surface. An example of the similar destruction of a much younger platform is to be found in the terraced plateaux of Skye, Eigg, Canna, Muck, Mull and Morven, which are portions of what was probably originally a continuous plain of basalt. Though dating back only to older Tertiary time, this plain has been so deeply trenched by denudation that it has been reduced to scattered fragments.

The Highlands are separated into two disconnected and in some respects contrasted divisions by the depression of the Great glen, extending from Loch Linnhe to Inverness. In the northwestern section the highest ground is found along the Atlantic coast, mounting steeply from the sea to an average height of 2,000 to 3,000 feet. The watershed consequently keeps close to the western seaboard, in some places not above 1½ m. from it. From these hills, which catch the first downpour of the rains from the ocean, the ground falls eastward. Numerous eminences, however, prolong the mountainous features to the North sea and south-eastward to Glen More. The difference of the general level on the two sides of the waterparting is reflected in the length of their streams. On the west the drainage empties itself into the Atlantic after flowing only a very few miles, on the east it has to run 30 or 40 miles. At the head of Loch Nevis the western stream is but 3m. long, while the eastern has a course of some 18m. to the Great glen. Throughout the north-western region uniformity of features characterizes the scenery, betokening, even at a distance, the general monotony of structure. But the sameness is relieved along the western coast of the shires of Sutherland and Ross and Cromarty by groups of cones and stacks, and farther south by the terraced plateaux and abrupt conical hills of Skye, Rum and Mull.

The south-eastern region of the Highlands, having a more diversified geological structure, offers greater variety of scenery. Most of the valleys, lakes and sea lochs run in a south-westerly and north-easterly direction, a feature strikingly exhibited in west Argyllshire. But there are also several important transverse valleys, that of the Garry and Tay, already noticed, being the most conspicuous example. The watershed, too, is somewhat different. It first strikes eastwards round the head of Loch Laggan and then swings southwards, pursuing a sinuous course till it leaves the Highlands on the east side of Loch Lomond. The streams flowing westward, however, are still short, while those running to the north-east, east and south-east have long courses and drain wide areas. There is a marked contrast between the configuration of the north-eastern district, and the other parts of this region. In that area the Grampians rise to level or gently rounded summits, often more than 3,000, and in a few places exceeding 4,000ft. in height, and bounded by steep declivities and sometimes by precipices. Farther south-west, in the shires of Perth, Inverness and Argyll, they give place to the more typical hummocky crested ridges of Highland scenery which, in Ben Nevis and Aonach Beg, reach heights of over 4,000 ft. Geological structure alone does not account for this contrast, and one reason may lie in the heavier rainfall, and consequently stronger erosion, to which the western mountains, facing the Atlantic ocean, have been exposed. Long narrow strips of flat land occur in the more important valleys. Most of the straths and glens have a floor of detritus which, spread out between the bases of the boundary hills, has been levelled into meadow land by the rivers and provides almost the sole arable ground in each district. It is appropriate here to notice certain terms common throughout Scottish topography in application to types of valleys and low-lying land, for examples of most of them are found in the Highlands or on their borders.

Straths are broad expanses of low ground between hills, usually traversed by one main stream and its tributaries—*e.g.*, Strath Tay, Strath Spey, Strath Conon. This name, however, has also been applied to wide tracts of lowland which embrace portions of several valleys, but are defined by lines of heights on each side; the best example is afforded by Strathmore—the "Great Strath" —between the southern margin of the Highlands and the line of the Sidlaw hills. This long wide depression, though it looks like one great valley, includes portions of the valleys of the Tay, Isla, North Esk and South Esk, all of which cross it. Elsewhere in central Scotland such a wide depression is known as a *howe*, as in the Howe of Fife between the Ochil and Lomond hills. A *glen* is a narrower and steeper-sided valley than a strath, though the names have not always been applied with discrimination. Most of the Highland valleys are true glens, Glencoe being the best known example. The hills rise steeply on each side, sometimes in grassy slopes, sometimes in rocky bosses and precipitous cliffs, while the bottom is occupied by a lake. In the south of Scotland the larger streams flow in wide open valleys called *dales*, as in Clydesdale, Tweeddale, Teviotdale, Liddesdale, Eskdale, Nithsdale. The strips of alluvial land bordering a river are known as *haughs*, and where, along estuaries, they expand into wide plains they are termed *carses*. The carses of the Forth extend seawards as far as Bo'ness and consist chiefly of raised beaches. The Carse of Gowrie is the strip of low ground intervening between the Firth of Tay and the Sidlaw hills. *Brae* signifies the steep bank of a river, and so any slope or hill-side.

Scottish lochs (or lakes) are sometimes classified into four groups—glen lochs, rock-tarns, moraine-tarns, and lochs of the Lowlands, of which the first and most important are practically confined to the Highlands and the second and third are far more numerous there than elsewhere. The small rock-tarns, lying in rock-basins on the flanks of mountains, or the summit of ridges, or rocky plateaux, are by far the commonest, and especially so in the north-west. They almost invariably lie in strongly

ice-worn platforms, and are held to occupy hollows produced by the gouging action of the ice-sheets in glacial times. Moraine-tarns—small sheets of water dammed back by moraines left by retreating glaciers—are also numerous in the Highlands, nestling in the bottoms of corries. In the south-west, where the glaciers continued longest to reach sea-level, lakes retained by moraine-barriers are found very little above the sea. More important, if less numerous than either of these categories, are the larger glen-lochs, which are associated with the finest inland scenery in the Highlands. These occupy depressions in the glens, not due to local heaping up of detritus, but true rock-basins, often of great depth. It is commonly but not invariably held that these depressions were formed by the erosive action of ice, since glaciers occupied the glens where they occur and wore down the rocks along the sides and bottom; but it is a point of difficulty in this theory whether ice could have eroded the deepest of the hollows. In any circumstances the lochs must be of recent geological date. Any such basins belonging to the time of the folding of the crystalline schists would have been filled up and effaced long ago, so rapid is the infilling by the torrents which sweep down detritus from the surrounding heights. Glen lakes are almost wholly confined to the western half of the Highlands. Hardly any lakes are to be seen east of a line drawn from Inverness to Perth. West of that line, however, they abound in both the longitudinal and the transverse valleys.

The western Highland coast is intersected throughout by long narrow sea-lochs or fiords. The mainland slopes steeply into the sea and is fronted by chains and groups of islands. These fiords are submerged land-valleys, for the whole western coast has subsided to a considerable depth beneath its former level. The Scottish sea lochs must be considered in connection with those of western Ireland and Norway. The whole of this north-western coast-line of Europe bears witness to recent submergence. On this view the Outer and Inner Hebrides were formerly one with themselves and the mainland, and the western isles therefore are truly grouped with the Highland province of Scotland. Nearly the whole coast-line is rocky. On the west the coast is mostly either steep rocky declivity or a sea-wall, though strips of lower ground are found in the bays. The cliffs vary in character according to the nature of the rock. At Cape Wrath, precipices 300ft. high have been cut out of the Archean gneiss. The varying texture of this rock, its irregular foliation and jointing, and its ramifying veins of pegmatite give it very unequal powers of resistance. Here it projects in irregular bastions and buttresses, there retires into deep recesses and tunnels, but shows everywhere a characteristic ruggedness. In striking contrast to these precipices are those of the Cambrian red sandstone a few miles to the east. Vast vertical walls of rock rise to a height of 600ft., cut by their perpendicular joints into quadrangular piers and projections, some of which stand out alone as islets in front of the main cliff. The sombre colouring is relieved by vegetation along the edges of the nearly flat beds which project like great cornices and serve as nesting-places for sea-fowl. Along the western sea-lochs raised sea-beaches sometimes afford the only arable soil, their flat green surfaces presenting a strong contrast to the brown moors above.

The population of the Highlands is naturally scattered, since great tracts of mountain and moorland are uninhabitable. The few small towns and larger villages are for the most part such as have grown in modern times as touring centres and places of summer residence along the west coast and the railways, in particular the line between Perth and Inverness. Settlements remote from these influences are commonly small, and some on the western seaboard share with Norwegian fjord-side settlements the characteristic of having their chief lines of access by water. The Highlands are not rich in minerals; only a few workings, such as that of the iron ore of Raasay, near Skye, are encountered; and only the modern development of hydro-electric power gives promise of any considerable industrial activity. This use of the water-power resources of the west, however, has already resulted in the establishment of aluminium works at Foyers and at Kinlochleven—the power itself being the sole attraction, for neither raw material, nor an easy line of commercial communication, nor even a potential industrial population, were available at these places. Further schemes are developing in Lochaber and the district near Mallaig. Otherwise, homestead industry, such as the manufacture of Harris tweed in the outer Hebrides, can maintain itself (apart from local consumption) only by the special excellence of its products. It thus follows that the Highland population is principally agricultural, and concentrated upon the limited cultivable areas, the resources of which it tends easily to outgrow, so that the Highlands have sent and still send abroad many emigrants. Only a few alluvial basins—up to an elevation of 1,200ft. in Banffshire, but usually much lower—the levels of raised beaches, and narrow isolated coastal strips offer fair agricultural land, and a more or less complete subsistence to the crofters, of whom those on the coast lands may add to their means of livelihood by fishing, while others may take service as gamekeepers on the large sporting estates which occupy a high proportion of the total area.

The North-eastern Region.—This division embraces the considerable low-lying areas in eastern Aberdeenshire and the northern parts of Banff, Elgin, and Nairn, together with the level strip of land bordering both sides of Moray firth. Farther north, the Highlands of Sutherland sink close to the coast, but the narrow coastal belt there broadens northward again in Caithness, which does not strictly belong to the Highlands. In the south-eastern part of the region (east and south-east of Moray firth) the principal rivers—Spey and Dee, and, within the angle formed by these, the Don, Ythan, Deveron, and others—drain long valleys separated by extended spurs of the Highland mountains. The hills sink to a fairly wide foreland, here sloping gently to the sea, there broken off in low cliffs. On this part of the coast there are neither islands nor deep inlets, though plenty of small bays offer shelter for shipping, especially fishing vessels. Northward, the coast is deeply indented by the Firths of Moray, Cromarty and Dornoch, and a further series of fine rivers, hardly less famous among salmon and trout fishermen than those just mentioned, enter the sea from the mountains to the west. The chief of these rivers are the Findhorn, Beauly, Conon, Shin, and Helmsdale. The peninsulas between the firths reach no great elevation—an extreme height of 800ft. is found in the Black Isle south of Cromarty firth. The coastal Lowland of Sutherland, as already indicated, is very narrow, but Caithness is a wide moor, terminating almost everywhere seaward in a range of precipices of Old Red sandstone.

The population of this region is, on the whole, closer on the coastal lands than in the interior; the largest towns, such as Aberdeen, Peterhead, Fraserburgh, Banff, Inverness, Wick, are seaports. In Sutherland population is almost confined to the raised beaches of the narrow coastal belt. On the other hand a fairly dense rural population covers most of the area between the lower Dee and the Deveron, and extends far up the valley of the Spey. The region is not devoid of very fertile lands, although their preparation for tilling has, in the past, necessitated in some parts immense labour in clearing the glacial boulders with which they were bestrewn. A high standard of farming is reached in the lower parts of the Dee and Don basins, the Laigh of Moray, and other localities. Oats and turnips, with some barley, are main crops, and the lower lands of the eastern division are famous for cattle. On the higher grounds sheep are more prominent. Granite is quarried at several points in the same division, and granite-polishing is a characteristic industry at Aberdeen. Pure water, favourable for malting, has helped in the establishment of the distilling industry. The fisheries centre mainly on Aberdeen, which is also the principal port for the export of herrings; the pelagic fisheries are carried on mostly from more northerly ports—Peterhead, Fraserburgh and Wick (as well as the Orkney and Shetland Islands).

The Central Lowlands.—These constitute a broad depression with south-westerly to north-easterly trend lying between the Highland line that runs from the head of the Firth of Clyde to Stonehaven and the pastoral uplands that stretch from Girvan to Dunbar. They may be regarded as a long trough of younger rocks let down by parallel dislocations between the older masses

to the south and north. The depression as such, however, is of great geological antiquity. Long dislocations have sharply defined its northern and southern margins. By other fractures and unequal movements of upheaval or depression portions of the older rocks have been brought up within the bounds of the younger, and areas of the younger have been enclosed by the older. On the whole, these disturbances have followed the prevalent north-easterly trend, and hence a tendency may be observed among the main ridges and valleys to run in that direction. The chains of the Ochil, Sidlaw, Pentland, Renfrew, Campsie and Fintry hills, and the valleys of the Strathmore, Firth of Tay, and the basin of Midlothian are examples. But the dominant cause in the determination of the topographical prominences and depressions of the district has been the relative hardness and softness of the rocks. Almost all the eminences in the Lowlands consist of hard igneous rocks, forming not only chains of hills such as those just mentioned and others in Ayrshire and Lanarkshire, but isolated crags and hills like those on which stand the castles of Edinburgh and Stirling, and others conspicuous in Fife and the Lothians.

Of the three chief valleys in the central Lowlands, two, those of the Tay and the Forth, descend from the Highlands, and one, that of the Clyde, from the southern Uplands. Though on the whole transverse, these depressions furnish another notable example of that independence of geological structure already referred to. The gorge in which the famous Falls of Clyde are situated is the best example of a river-gorge in the Lowlands. Lochs are not many. Occasional rock-tarns are found in the hills. The larger lochs of the Lowlands lie in hollows of the glacial detritus, which is strewn thickly over the lower grounds. As these hollows were caused by original irregular deposition rather than by erosion, they have no intimate relation to the present drainage-lines. The lakes vary in size from pools to sheets of water several square miles in area. As a rule they are shallow in proportion to their extent and surface. They were once more numerous than they are now, for some have disappeared through natural causes and others have been drained. The largest sheets of fresh water in the Lowlands are lakes of the plains, as Loch Leven and the Lake of Menteith.

The fact that two-thirds of the population of Scotland live in the central Lowlands on one-tenth of the total area of the country, is evidence of the pre-eminent industrial position of this region. Among the geographical reasons for that pre-eminence we find, first, ease of communication, both internal and external. The Firth of Clyde on the west, the Firths of Forth and Tay on the east, deeply indent the coasts and offer access for shipping directly or very near to the chief industrial centres. Secondly, the Carboniferous rocks of the Lowlands carry important coal-fields, the richest that of Lanarkshire, others in Ayrshire, about the head of the Firth of Forth, in the Lothians and in Fife. Iron is allied with coal, notably in the Ayrshire and Lanarkshire fields. Oil-shale is worked in Midlothian and Linlithgowshire, but its importance has declined; lead is worked in Lanarkshire. Upon the Lanarkshire coal-field, the city of Glasgow, and its neighbouring industrial towns, there centre a variety of great manufacturing industries—shipbuilding and engineering, cotton, woollen and linen manufactures, brewing and distilling, chemical, pottery and glass manufactures, and many others. Elsewhere certain great industries are definitely localized, such as the jute manufacture and jam and marmalade making at Dundee; the woollen industry in Stirlingshire and Clackmannanshire, linen manufacture at and about Dunfermline, Arbroath and Montrose, that of linoleum and oilcloth at Kirkcaldy, that of paper in places neighbouring to Edinburgh, and the dyeing industry at Perth. All depend now upon the coal supplies; the woollen manufactures were based originally upon the neighbourhood of wide hill-pastures for sheep, the jam-making of Dundee upon the fertile fruit-lands in the adjacent Carse of Gowrie and Strathmore; and all the textile industries, the paper mills, and the distilleries owe their establishment in part to ample supplies of pure water. Rich agricultural lands, albeit restricted in area, lie close to the manufacturing districts, especially in the east, in Perthshire, Forfarshire, Fife and the Lothians; barley, a high yield of wheat on a small acreage, and potatoes are crops especially noted.

The Southern Uplands.—These extend from the north channel in the south-west to St. Abb's head in the north-east, and form a well-defined belt of hilly ground, and though much less elevated (their highest point is 2,764ft. above the sea) than the Highlands, rise with scarcely less abruptness above the lower tracts that bound them. Their north-western margin for the most part springs boldly above the fields and moorlands of the central plain, and its boundary for long distances continues remarkably straight. On the south and south-east their limits in general are less prominently defined but are better seen west and south-west of the Nith, from which they extend to the sea and Loch Ryan, terminating in the extreme south-west in a plateau of which the loftiest point is little over 1,000ft. above the sea. The Cheviots do not properly belong to the Uplands, from which they are separated by Liddesdale and other hollows, and on which they abut abruptly. But though geologically the one set of mountains must be separated from the other, geographically it is convenient to include within the southern Uplands the whole area between the central plain and the Border. A survey of the Uplands, therefore, presents in succession from south-west to north-east the Kirkcudbrightshire and Ayrshire mountain moors, the Lowthers, the Moffat hills, the Moorfoots and the Lammermuirs. Distinguished by the smoothness of their surface, they may be regarded as a rolling moorland, traversed by many valleys conducting the drainage to the sea. This character is well observed from the heights of Tweedsmuir. Wide, mossy moors, 2,000ft. or more above the sea, and sometimes level as a racecourse, spread out on all sides. Their continuity, however, is interrupted by numerous valleys separating them into detached flat-topped hills, seldom marked by precipices of naked rock. Where the rock projects it more usually appears in low crags and knolls, from which long trails of grey or purple debris descend till they are lost among the grass. These smooth green hills form excellent pasture-land, while the alluvial flats in the valleys, and even some of the lower slopes, are fitted for grain and green crops. Only in the higher tracts are there rugged features recalling the character of Highland scenery. In the heights of Hartfell (2,651ft.) and Whitecoomb (2,695 ft.), whence the Clyde, Tweed, Annan and Moffat Water descend, the high moorlands have been scarped into gloomy corries, with crags and talus-slopes, which form a series of landscapes all the more striking from the contrast with everything around them. In Galloway, also, the highest portions of the Uplands have acquired a ruggedness and wildness more like those of the Highlands than any other district in the south of Scotland. In that region the Silurian rocks have been invaded by large bosses of granite, and have undergone a variable amount of metamorphism which has, in some places, altered them into hard crystalline schists. These various rocky masses have yielded unequally to disintegration; the harder portions project in rocky knolls, crags and cliffs, while the softer parts have been worn down into more flowing outlines. The highest summit in the south of Scotland—Merrick (2,764ft.)—consists of Silurian strata much altered by proximity to the granite, while the rest of the more prominent heights (all in Kirkcudbrightshire)—Rinns of Kells (2,668ft.), Cairnsmuir of Carsphairn (2,612ft.), and Cairnsmore of Fleet (2,331ft.)—are formed of granite.

The watershed of the southern Uplands runs from the mouth of Loch Ryan in a sinuous north-easterly direction, keeping near the northern limit of the region till it reaches the basin of the Nith, where it quits the Uplands, descends into the lowlands of Ayrshire, and, after circling round the headwaters of the Nith, strikes south-eastwards across half the breadth of the Uplands, then sweeps north and eastwards between the basins of the Clyde, Tweed and Annan, and then through the moors that surround the sources of the Ettrick, Teviot and Jed, into the Cheviot hills. Here, again, the longest slope is on the east side, where the Tweed bears the whole drainage of that side into the sea. Although the rocks throughout the southern Uplands have a persistent north-easterly and south-westerly strike, and though this trend is apparent in the bands of more rugged hills that mark the outcrop of hard grits and greywackes, nevertheless geological

structure has been much less effective in determining the lines of ridge and valley than in the Highlands. On the southern side of the watershed, in Dumfriesshire and Galloway, the valleys run generally transversely from north-west to south-east. But in the eastern half of the Uplands the valleys do not appear to have any relation to the geological structure of the ground underneath.

In the southern Uplands, owing to the greater softness and uniformity of texture of the rocks, as compared with those of the Highlands, rock-tarns are comparatively infrequent, except in Galloway, where the protrusion of granite and its associated metamorphism have reproduced Highland conditions of rock-structure. The best known and one of the most picturesque of moraine-dammed lochs is the wild and lonely Loch Skene, lying in a recess of Whitecoombe at the head of Moffat water. Others are sprinkled over the higher parts of the valleys in Galloway.

On the east the southern uplands plunge abruptly into the sea near St. Abb's head in a noble range of precipices 300 to 500 ft. in height, and on the west terminate in a long broken line of sea-wall, which begins at the mouth of Loch Ryan, extends to the Mull of Galloway and reappears again in the southern headlands of Wigtown and Kirkcudbright. Southward they sink to the narrow Lowland bordering Solway firth.

On the grassy hills of the Uplands, from end to end, sheep farming is naturally an outstanding occupation, and with it is associated the woollen industry centred in the chief inland towns of the Tweed basin. In the west (Galloway, Ayrshire) dairy farming is highly developed for the supply of the neighbouring populous centres in the Lowlands. Into the western dales, too, some of the industries of the Lowlands extend, with some coal-mining in Nithsdale, quarrying of freestone, etc., while the granite of Creetown and the neighbourhood is famous. But, as a whole, the human, like the physical, geography of the southern Uplands, is clearly differentiated from that of the Highlands and the Lowlands; it approaches more nearly in character to that of our north-eastern region. (O. J. R. H.)

GEOLOGY

Scotland lies in the course of a pre-Devonian mountain chain that stretches from Scandinavia to Ireland. This chain, called Caledonian by Suess, dominates the early geological history of the country. The general course of its structures is north-east-south-west. Its foreland is in the Outer Hebrides, its front in the north-west Highlands. Its latest manifestation is the corrugation of the Silurian of the Southern Uplands—where Lapworth demonstrated the true worth of graptolites.

Pre-Devonian of the North-west Highlands and Islands.—The oldest rocks are grouped as Lewisian Complex. They make the greater part of Lewis, with its companion Outer Hebrides, and much of the coast of the adjacent mainland. Apparently, their earliest members consist of metamorphic sediments, including magnesian marbles and graphitic schists. Into these are intruded igneous gneisses (intermediate, basic, etc.). Locally, late dykes of the complex have escaped metamorphism. The Lewisian abounds in records of pre-Torridonian movements executed under diverse conditions. Two phenomena have attracted particular attention: transformation of dolerite into hornblende-schist, and production by frictional fusion of so-called "flinty" crush-rock. A great development of "flinty" crush-rock follows an east-south-eastwardly inclined thrust-plane along the Outer Hebrides.

Torridonian succeeds Lewisian with complete unconformity. From Islay northward to Skye, the Lower Torridonian basal conglomerates, epidotic grits, grey sandstones, flags and grey and black shales reach a collective thickness of 7,000 feet. Farther north, Middle Torridonian arkose (6,000–8,000 ft.), with local breccias, rests among and covers over "fossil hills" of Lewisian gneiss which are sometimes more than 2,000 ft. in individual height. Upper Torridonian sandstones, flags and shales attain 4,500 feet.

The Durness Quartzite-limestone.—This succession begins at or below the Lower Cambrian and, according to American palaeontologists, extends into the Lower Ordovician (Durness lithology and fauna are of American facies). The base passes smoothly and unconformably across Torridonian east-south-eastwards on to Lewisian exposed in a pre-Cambrian anticline. The stratigraphy is persistent for 100 miles along the strike: basal quartzite, 320 ft.; quartzite with vertical worm "pipes," 270 ft.; dolomitic shales, mudstones and dolomites, with *Olenellus*, etc., 50 ft.; grit, with *Salterella* and also *Olenellus*, 30 ft.; limestones and dolomites in seven stages, some fossiliferous, 1,500 feet. Plutonic (possibly early Devonian) intrusions of alkali-syenite, borolanite, etc., accompanied by sills, cut the Durness sediments. Contact effects include dedolomitisation.

The Durness fossiliferous succession with its intrusions passes east-south-eastwards in disturbed fashion under the Moine Thrust overlain by crystalline schists. This thrust has been traced from Durness to Skye, and may continue through Islay. Near Durness, a thrust-outlier (Klippe) of the Moine Thrust-mass (nappe) has been preserved by down-faulting 10 miles in advance of the main outcrop. In Assynt and Glencoul, there are particularly good exposures of the disturbed belt with subsidiary thrusts bringing 1,500 ft. slices of Lewisian for miles over Cambrian. Recumbent folding occurs in and near Skye. Isoclinal packing, *schuppen Struktur*, crushing (mylonisation), slaty cleavage, etc., are diagrammatically exposed at many localities.

Pre-Devonian of the Highlands South-east of Moine Thrust.—Sedimentary quartzo-felspathic schist or gneiss, with sufficient mica to give a flaggy structure, is prevalent north-west of the Caledonian canal. Micaceous gneiss representing shales is also common. Such rocks are grouped together as Moine Schists. A limestone with particular associates occurs a little above the Moine Thrust in Eireboll. Several minor outcrops of Lewisian igneous and sedimentary types are generally interpreted as Lewisian inliers interfolded with unconformable Moines. The Inchbae porphyritic granite, now largely augen-gneiss, was intruded into the Moines before these had suffered regional metamorphism. Much of the resultant indurated hornfels, escaping subsequent deformation, retains minutiae of sedimentary structure, such as grains, ripple-marks and sun-cracks. The Moine Schists seem to decrease in metamorphism, near the Moine Thrust, but evidence is blurred by crush-phenomena. In Skye there is a thrust-mass under the Moine Thrust, the rocks of which are variously interpreted as Moines or Torridonian. Some think all Moines are metamorphosed Torridonian; most regard the Moine Metamorphism as pre-Torridonian.

Moine-like rocks cross the Caledonian canal fault, but half of this south-eastern district consists of a varied assemblage of undated sedimentary schists known as Dalradian. Quartzites, limestones and graphitic schists are characteristic members; the Schichallion conglomerate may be glacial; pillow lavas occur at Loch Awe; basic intrusions are wide-spread; granites, that have shared to some extent in the movements, are common in the east. The Dalradians overlie Moine-like rocks, pitching off them towards Loch Awe and Banffshire. Large-scale recumbent folds with fold-faults (slides), the whole refolded, are typically shown at Ballachulish and elsewhere.

Zonal mapping of regional metamorphism was first carried out in the Dalradian belt. The grade, varying from sillimanite-gneiss to roofing slate, is low at Loch Awe, in Banffshire and along the south-eastern Highland border.

Probable Upper Cambrian pillow lavas, radiolarian cherts and fossiliferous shales outcrop discontinuously along the Highland border fault. In Arran they overlie Dalradians. Farther north-east they are associated with a grit and conglomerate group (Margie Beds) and appear overthrust by Dalradians. At Stonehaven they are unconformably overlain by uppermost Silurian (Downtonian) sandstones with mudstones, tuffs and conglomerates (2,760 ft.), that yield fish and *Dictyocaris*.

Silurian of Lesmahagow and Pentland Anticlines in the Central Valley.—Lesmahagow exposures of Silurian show: Wenlock greywacke and shale (base not seen), 1,300 ft.; Ludlow mudstone, greywacke and shale 1,480 ft.; Downtonian yellow, red and chocolate sandstone with two conglomerates and some

mudstone, 2,700 feet. The Wenlock-Ludlow rocks have yielded many brachiopods and molluscs, especially in the Pentlands, also scorpion, phyllocarids, eurypterids and fish. The three last appear again in the Downtonian, accompanying a transition from marine to Old Red Sandstone conditions.

Ordovician and Silurian of the Southern Uplands.—Closely packed isoclinal folding (seldom accompanied by cleavage) and rapid cross-strike change of facies are characteristic. Nothing older than Arenig has been recognised. The succession is marine and ends with Wenlock near Girvan and with Ludlow on the English Borders.

The Ordovician commences with Arenig pillow lavas capped by Arenig-Llandeilo radiolarian cherts (70 ft.). Near Girvan 1,500 ft. of Arenig volcanic rocks are cut by serpentine, gabbro and granite which erosion bared before deposition of conglomeratic Upper Llandeilo (830 ft., including 60 ft. interbedded fossiliferous Stinchar limestone). South-east of Stinchar Valley, Upper Llandeilo suddenly becomes conformable to the radiolarian cherts and consists of mudstones and grits (500 ft.) and conglomerate (500 ft.). Farther south-east it passes to grit and greywacke (1,000 ft.) and then near Moffat to 20 ft. of graptolite shale (Glenkiln). The Caradoc (including Ashgillian) at Girvan is mostly mudstones, grits, flags and shales (2,800 ft.) with interbedded shelly and graptolitic faunas. Near Moffat this reduces to 100 ft. of graptolite shale and barren mudstone (Hartfell). Acid lavas occur at Wrae.

A general palaeontological break introduces the Silurian, although there was no upheaval at Moffat. The Llandovery at Girvan consists of conglomerates, grits, flags, shales and thin limestones (1,050 ft.) with interbedded shelly and graptolitic faunas. Near Moffat there are only 100 ft. of graptolite shale (Birkhill). The Tarannon, both at Girvan and Moffat, consists of grits, flags and shales with occasional graptolitic intercalations. This series is thinner and finer-grained at Girvan (2,100 ft.) than at Moffat (3,000 to 4,000 ft.). Wenlock is doubtfully represented near Girvan by conglomerates, grits, flags and shales, (500 ft. preserved) with minor graptolitic and shelly layers. Near the English Borders Wenlock conglomerates, grits, greywackes, shales and mudstones (1,000 to 1,500 ft.) contain several graptolitic bands with occasional eurypterids. Shelly layers also occur. In the same district Ludlow mudstones with limestone-nodules and grits (500–750 ft.) yield shells.

The Llandeilo unconformity at Girvan is probably a partial continuation of the post-Cambrian pre-Downtonian unconformity at Stonehaven. Upper Llandeilo and subsequent Ordovician and Silurian rocks of the southern Uplands tell of derivation of sediment from the north-west. Much of their material can be referred to denudation of Cambro-Arenig lavas, cherts and plutonics. Quartzite appears as pebbles in the Caradoc, and mica-schist in the Llandovery.

Undated post-Silurian mineral veins occur at Lead Hills.

Devonian.—The Scottish Devonian is wholly continental Old Red Sandstone. Three divisions are recognised with distinct faunas and floras. Fish have furnished most of the determinable fossils. The Lower Old Red Sandstone or Caledonian is most fully preserved in the Central Valley (19,000 ft., including lavas, Kincardineshire). A widespread type is dull purplish brown sandstone. Upper members in Strathmore are red sandstones and marls. Conglomerates attain great prominence towards the Highlands and southern Uplands. North-westwards there is conformity with Downtonian (Lesmahagow and Stonehaven) and violent unconformity with schists (within Highlands). South-eastwards there is violent unconformity with Downtonian, etc. (Pentlands, Girvan, Cheviot). A basal conglomerate of Silurian greywacke extends north-westward to Lesmahagow. Volcanic rocks (basalts, andesites, rhyolites) occupy a roughly central position in the Lower Old Red sequence (6,500 ft. in Ochils, well exposed also Pentlands to Ayrshire). In the Highlands (Oban, Glen Coe, Ben Nevis) and also at Cheviot, lavas greatly exceed sediment. Glen Coe and Ben Nevis are famous for cauldron-subsidences. At both localities granites (or granodiorites) with north-eastern dyke-swarms are later than the lavas. Granites cutting Lower Old Red Sandstone also occur at Distinkhorn (Ayrshire) and Cheviot. Others cut folded Silurian (southern Uplands). Many undated Highland granites are probably of Lower Old Red age, but granite pebbles are well known in Lower Old Red Sandstone conglomerates (Glen Coe, Stonehaven).

Middle Old Red Sandstone or Orcadian is widely developed in north-east Scotland (18,000 ft. in Caithness). It largely consists of flags, often bituminous, calcareous, ripple-marked and sun-cracked. The earlier part of the Orcadian is restricted to Caithness, but later divisions extend into Orkney and round the Moray Firth. The Rhynie Chert with wonderfully preserved plants is generally referred to the Orcadian. The Upper Old Red Sandstone (some thousands of feet thick) is found in the Central Valley and north-east Scotland. The Lower Old Red Sandstone was locally much faulted, folded and eroded before the deposition of the Upper. The Upper is also unconformable to the Middle, except perhaps in Shetland. Red sandstones with some wind-rounded grains are common in the earlier parts of the Upper Old Red Sandstone; while paler sandstones with cornstones occur towards the conformable base of the Carboniferous.

Carboniferous.—The Scottish Carboniferous, a marine, estuarine and terrestrial accumulation, is typically developed in the Central Valley and along the English Borders. The two areas of deposition were always connected across the east end of the southern Uplands. Farther west (Sanquhar) Upper Carboniferous rests on Silurian. In the Highlands, Carboniferous is scarcely known (Campbeltown, Bridge of Awe, Morven). In the Central Valley and on the Borders, it follows Upper Old Red Sandstone conformably, though with a palaeontological break. Measurements of sub-divisions in Edinburgh district are: Calciferous Sandstone Series, including Cementstone Group (1,000 ft.) and Oil Shale Group (3,000 ft.); Scottish Carboniferous Limestone Series, including Lower Limestone Group (700 ft.), Limestone (or Edge) Coal Group (1,050 ft.), and Upper Limestone Group (1,050 ft.); Millstone Grit (800 ft.); Productive Coal Measures (1,500 ft.); Barren Red Coal Measures (in Ayrshire, 1,500 ft.). Palaeontologically, the sequence is important for its abundant Lower Carboniferous land plants and estuarine fishes. These are completely replaced by English Upper Carboniferous forms one-third way up the Millstone Grit.

Economically, the oil shale and the two widely separated coal-bearing groups (with ironstones) are very valuable. Marine limestones are scarcely represented except in the Lower and Upper Limestone Groups (near Edinburgh, 8 beds reach the quite exceptional total of 230 ft.). A well-known 40-ft. fresh-water limestone (Burdiehouse) occurs in the Oil Shale Group. Rapid variations of group-thicknesses are characteristic. Near Patna in Ayrshire, the Lower Limestone Group reduces from 70 ft. to 30 ft., the Limestone Coal Group from 260 ft. to 100 ft., the Upper Limestone Group from 700 ft. to 40 ft., and the Millstone Grit from 390 ft. to 120 ft. in a distance of 2 miles. The floor of deposition evidently subsided in independently moving blocks. Change of facies is exemplified by the restriction of workable oil shale to West Lothian and its borders. Vulcanicity is common till the close of the Millstone Grit. Special activity reigned about the end of the Cementstone Group (Clyde Plateau, Arthur's Seat, Calton Hill). Products include essexitic basalts, mugearites, trachytes and phonolites. Contemporaneous weathering of Millstone Grit basalts has given valuable bauxitic clay (Ayrshire).

New Red Sandstone.—The Scottish deposits are of continental facies. A train of outcrops reaches intermittently across the southern Uplands and Central Valley from the Solway to Arran. In Ayrshire, lavas and tuffs (basalt and nepheline-basalt, 500 ft.) underlie brick-red desert sandstone (1,500 ft.). The volcanic period was one of faulting and was further marked by ash-necks and doleritic intrusions, some (essexitic) carrying nepheline, others quartz. It may correspond roughly with the Permo-Carboniferous intrusion period of many quartz-dolerite sills and east to west dykes between Stirling and Northumberland. In Arran brick-red desert-sandstone (2,000 ft.) underlies breccia, sandstone, and interbedded sandstone and marl with occasional nodular limestone. The top division, probably Keuper, is over-

lain, in a fallen mass within a Tertiary volcanic neck, by *Pteria contorta* shales (Rhaetic).

The base of the Mesozoics from Mull northwards consists of Trias conglomerates and sandstones with concretionary cornstones. Red colouration is often subordinate. In Western Mull 200 ft. of these rocks underlie 40 ft. Rhaetic with *Pteria contorta*. Elsewhere Rhaetic is only doubtfully distinguishable.

In Elgin two outliers of New Red Sandstone have yielded remarkable reptilian faunas. One of these outliers is of marked desert character and perhaps of Permian age, the other outlier is certainly Trias.

Jurassic.—Low-lying outcrops of Jurassic, conformable to Trias, are preserved on the west and east coasts of the Highlands. On the west, where a cover of Tertiary lavas has furnished additional protection, the type area is Skye and Raasay: Lower Lias (Broadford Beds, mostly limestone, 240 ft.; Pabba Shales, 600 ft.); Middle Lias (Scalpa Sandstone, 240 ft.); Upper Lias (shales, 70 ft.; Raasay Ironstone, 8 ft.); Inferior Oolite (shales, 70 ft.; sandstone, 600 ft.); Great Estuarine Series (sandstone, bituminous shale and limestone, 400 ft.); Cornbrash (limestone with comminuted fossils, only in Raasay, 20 ft.); Callovian (sandstone remnant in Skye); Upper Oxfordian (grits, Skye, 80 ft.) followed by Upper Oxfordian and Corallian (shales, Skye, 220 ft.). The sequence also reaches Corallian in Eigg, but in Ardnamurchan and Mull ends with Inferior Oolite. The Hebridean marine faunas are as rich as any in Britain. The Great Estuarine Series, agreeing in age with the Yorkshire Upper Estuarine Series, contains *Cyrena, Viviparus, Ostrea,* etc.

At Brora on the east coast are remarked: Lower Lias (shales, 80 ft.); Great Estuarine Series (over 80 ft. shale, sandstone, etc., with 3 ft. Brora Coal at top); Callovian (limestone, 5 ft.); Lower Oxfordian (shales, 275 ft.); Upper Oxfordian and Corallian (sandstone, 200 ft.); Kimmeridgian (sandstone and bituminous shale, 100 ft.; boulder-beds and shales, 500 ft.). The boulders of the boulder-beds consist of Old Red Sandstone. Many are big; one measures 150×90×30 ft. They have fallen from a moving submarine fault-scarp and are mixed with corals and shells. The throw of the fault exceeds 2,000 ft. In Skye another 2,000 ft. post-Corallian fault can be shown to have been planed down by erosion before Upper Cretaceous times.

Cretaceous.—Scotland is embraced within the scope of the great Upper Cretaceous marine transgression. The Upper Cretaceous rests indifferently on Lower Lias and later Jurassic rocks. It is known *in situ* (Skye, Scalpa, Raasay, Eigg, Mull, Morven), as block remanié in a Tertiary vent (Arran), and as remanié flints (Aberdeenshire). The Morven succession is: Cenomanian Greensand (45 ft.); White Sandstone (35 ft.); Silicified Chalk with *Belemnitella mucronata* (5 ft.). This condensation of the succession is typical of the Hebrides. The White Sandstone consists of desert sand blown on to the Scottish shore of the Franco-Britto-Russian Chalk sea. In Morven, Cretaceous is still preserved 1,600 ft. above sea-level.

Tertiary.—The Cretaceous Chalk was upraised, weathered and silicified and its crannies filled with desert sand (Mull). Subsequent conglomerate and lateritically weathered ash bespeak a change to moist climate and volcanic eruptions. Subaerial basalt lavas characterise Skye, Eigg, Mull and Morven. Leaf-beds intercalated near their base suggest early Eocene (Ardtun). Exceptionally these lavas are columnar (Staffa). The basalt succession in Mull is: olivine-rich, 3,000 ft.; olivine-poor, 3,000 ft. The Sgur of Eigg pitchstone seems to be an acid lava that flowed down a valley, the sides of which, consisting of basalt, have since been eroded away. Great plutonic centres occur at St. Kilda, Skye, Rum, Mull, Ardnamurchan and Arran. Some think that most of the lavas, still preserved, were fed from these centres. A Kilauean sink, repeatedly renewed in central Mull, was often occupied by a crater-lake, and lavas flowing into it developed pillow-structure. Vent-agglomerates are abundant in Skye, Mull, Ardnamurchan and Arran. In the last named island, the latest surface-rock *in situ* is Keuper, but masses of Rhaetic, Lias and Chalk have tumbled into a Tertiary vent and thus escaped erosion.

The Skye plutonic centre is well known for its gabbro to granophyre succession; Rum for its peridotites; Mull and Ardnamurchan for their ring-dykes—in Mull the plutonic succession is very complex and begins with granophyre, in Ardnamurchan it is essentially gabbroidal; Arran is specially noteworthy for the doming of its granite's roof—peripheral folding is a related feature in Mull. Cone-sheet complexes are extensively developed in Skye, Mull and Ardnamurchan. The Skye, Rum, Mull and Arran centres have crowded dyke-swarms. The general dyke-direction is north-westerly, but this is combined with a radial tendency in Rum. Some believe that most of the Hebridean lavas were fed from dykes (fissure eruptions). It is certain, however, that the great centres were established before the dyke-swarms, since they locate the latter. It is also certain that most of the dykes are later than any lavas spared by erosion.

West Highland scenery has been shaped entirely since the early Tertiary eruptions. The magnificent mountain and valley forms of Skye are cut in Tertiary plutonics.

Possible Pliocene gravel occurs near Turriff, Fyvie and in Central Buchan, all in Aberdeenshire.

Pleistocene and Recent.—During the Glacial Period, Scotland functioned as a complex centre of dispersal within the great North European ice-sheet. Scandinavian currents were almost excluded except in Shetland, whilst Scottish currents freely invaded England. Some districts were crossed by ice that traversed the sea-bed bringing in shells and, in Caithness, Mesozoic erratics. Glacial erosion is often pronounced. Crag and tail is developed to perfection in Edinburgh and elsewhere. Rock basins are numerous in the Highlands, with Loch Coruisk as a diagrammatic example. Characteristic deposits are: West Highlands, hummocky moraines; East Highlands, fluvio-glacial gravel; Lowlands, boulder clay, either flat or in drumlins, and gravel kames. In Glen Roy glacially dammed lakes are recorded by conspicuous strand-lines, and throughout most of eastern Scotland glacially diverted rivers can be traced by channels now left dry.

Raised beaches up to about 100 ft. occur round Scotland, but not in the Outer Hebrides, Orkneys and Shetlands. The higher beaches are late Glacial and are locally interfered with by glacial readvance (Loch Lomond and Mull). The best marked beach, often about 30 ft., has a temperate fauna. It rests in places on a peat or forest bed that continues below sea-level. Traces of early man are found in this raised beach. (E. B. B.)

FLORA AND FAUNA

Vegetation.—Geographical usage places Scotland within the cool-temperate forest division of the Northern Hemisphere, but in doing so implies no more than that Scotland lies between those latitudes within which neither arctic nor sub-tropical vegetation is characteristic, and that the conditions are those of a land under maritime, not interior-continental, climatic influence. Actually forests—extensive tree-covered areas, as distinct from the treeless "deer forests" of Scottish phrase—are practically absent in Scotland; wooded tracts are of no great extent and are scattered, save in so far as they appear mainly upon the eastern and southern borders of the Highlands. They consist mostly of conifers and oaks. Native species are few. Apart from destruction by man (which has in some measure been offset by planting) it is clear that Scotland, separated from Europe relatively soon after the final glacial epoch, was poorly colonized by north-European species of trees. A damp climate, imperfect drainage and wet soil, and unfavourable exposure to prevalent winds over wide areas, are further reasons adduced for the poverty of the growth. The upper limit of trees lies about 2,000ft. above sea-level in the southern Uplands, and somewhat below that height (1,700–1,900ft.) in the central Highlands; farther north, it falls to 1,200–1,400ft. in central Sutherland, and lower still in the extreme north. Types of vegetation in the Highlands may in a measure be localized. Thus, peat moors of wide extent occur in definite areas—in Sutherland and Caithness most notably; also, in the south, on the moor of Rannoch and about Lochs Awe and Etive, between the heads of Lochs Fyne and Lomond, and to the east of Callander, and on the long eastern flanks of the region. Marshy grass lands have

a wider extent in the west than in the east, in sympathy with the higher rainfall of the west; they are interspersed with drier mountain and pasture lands, usually at higher levels, with better drainage on the steeper slopes; while a definitely drier type of moorland occurs at lower levels in the north-west and on the outer islands, where the surface is much broken. Heath moors, as distinct from grass moors, occur widely both in the Highlands and on the southern Upland, but they are by far the more characteristic on the east side of the Highlands generally than on the west, and especially on the Grampian heights. The wide expanse of grassy hill-pasture on the southern uplands has already been mentioned, and indications have been given of the distribution of agricultural lands in the respective regional divisions. But the main localization of agricultural lands may be indicated briefly as occurring in an eastern belt following the curves of the coast between the Firths of Dornoch and Forth, with some extension north of the first and south of the second; for the rest, such lands, except in the non-industrial parts of the central Lowlands and in the dales and on the western slopes of the southern Uplands, are strictly limited in area. At certain points on all the coasts, but most notably the east, extensive sand-dunes, with their characteristic vegetation, are found. Finally, reference is due to the alpine and arctic types of plants, such as saxifrages and mountain willow, which are common on Highland summits above some 2,000ft. of elevation, though Ben Lawers (3,982ft.), above Loch Tay, is usually cited as offering examples of particular interest.

Fauna.—Deer-forests cover over 2¼ million acres. The red deer in Scotland is confined to the Highlands, but the roe-deer, living in woods, is found also in the southern Uplands in some parts where tree plantation has been carried out. Other kinds of the larger mammals, once abundant, are now extinct; the last wolf is said to have been killed in 1680. The wild cat survives in the Highlands; as also the otter, polecat, ermine and pine marten. Rabbits and hares are abundant, including both the common and the mountain hare, of which the last assumes a white coat in winter. Grouse moors occupy an extensive area; ptarmigan and blackcock, among other game birds, are found in many districts, and the capercailzie has been reintroduced. The golden eagle and the white-tailed eagle haunt only the remoter mountainous districts; other large birds of prey, such as the osprey and kite, are also becoming scarce. The islands and sea-cliffs, and some of the inland lochs, are frequented by a great variety of water-fowl. The Scottish lochs are noted in particular for salmon and trout; of this family there are several varieties, one of which, the Loch Leven trout, is peculiar to the loch of that name. Some arctic crustacea occur among the loch fauna; and a marine crustacean (*mysis*) appears to have migrated from the coastal waters to certain freshwater lochs not far from sea-level.

POPULATION

At the end of the 15th century it is conservatively estimated that the population of Scotland did not exceed 500,000—Edinburgh having about 20,000 inhabitants, Perth about 9,000, and Aberdeen, Dundee and St. Andrews about 4,000 each. By the Union with England (1707) the population is supposed to have grown to 1,000,000. In 1755, according to the returns furnished by the clergy to the Rev. Dr. Alexander Webster (1707–1784), minister of the Tron kirk, Edinburgh—who had been commissioned by Lord President Dundas to prepare a census for Government—it was 1,265,380.

At the first Government census (1801) it had reached 1,608,420. The increase at succeeding decades has been continuous though fluctuating in amount. After 1841, however, the population in several Highland shires—in which the clearance of crofters to make way for deer was one of the most strongly-felt grievances among the Celtic part of the people—in the islands, and in some of the southern counties, diminished. In 1931 the population amounted to 4,842,554 (females 2,516,687) showing a decrease of 0·8% on the 1921 figures, the first decrease to be recorded.

In 1921 there were 162 persons to each square mile, and 3·9 acres (excluding inland waters, tidal rivers and foreshore) to each person. The distribution of population is illustrated in the above table, in which is given the names and areas of the counties.

Area and Population of Civil Counties in 1931

Civil counties	Area in acres	Population	Increase or decrease % since 1921	Pop. per square mile
1. Northern:				
1. Shetland .	352,319	21,410	−16·1	38
2. Orkney .	240,847	22,075	− 8·4	58
3. Caithness .	438,833	25,656	− 9·3	37
4. Sutherland .	1,297,914	16,100	− 9·6	8
2. North-western:				
5. Ross and Cromarty.	1,977,248	62,802	−11·3	20
6. Inverness .	2,695,094	82,082	− 0·5	19
3. North-eastern:				
7. Nairn . .	104,252	8,294	− 5·6	50
8. Moray . .	304,931	40,805	− 1·8	86
9. Banff . .	403,053	54,835	− 4·3	87
10. Aberdeen .	1,261,521	300,430	− 0·2	152
11. Kincardine .	244,482	39,864	− 4·6	104
4. East Midland:				
12. Forfar . .	559,037	270,190	− 0·3	309
13. Perth . .	1,595,805	120,772	− 3·8	40
14. Fife . .	323,012	276,261	− 5·7	551
15. Kinross. .	52,392	7,454	− 6·4	92
16. Clackmannan	34,927	31,947	− 1·8	591
5. West Midland:				
17. Stirling. .	288,842	166,447	+ 2·9	369
18. Dumbarton .	156,927	147,751	− 1·9	602
19. Argyll . .	1,990,472	63,014	−18·0	20
20. Bute . .	139,658	18,822	−44·2	86
6. South-western:				
21. Renfrew .	151,431	288,575	+ 0·7	1222
22. Ayr. . .	724,251	285,182	− 4·7	252
23. Lanark. .	564,567	1,585,968	+ 2·2	1801
7. South-eastern:				
24. W. Lothian .	76,861	81,426	− 3·0	678
25. Midlothian .	234,325	526,277	+ 3·9	1437
26. E. Lothian .	170,971	47,369	− 0·2	177
27. Berwick .	292,535	26,601	− 5·8	58
28. Peebles. .	222,240	15,050	− 1·8	43
29. Selkirk . .	170,793	22,608	−....	85
8. Southern				
30. Roxburgh .	426,028	45,787	+ 1·8	68
31. Dumfries .	686,302	81,060	− 0·5	75
32. Kirkcudbright	575,832	30,341	− 2·3	33
33. Wigtown .	311,984	29,299	− 4·8	60

In the northern, north-western, north-eastern and southern divisions the population declined during the decade, 18 counties being thus affected. It will thus be seen that the far north and far south alike decreased in population, the decline being largely due to physical conditions, though it need not be supposed that the limit of population was reached in either area. The most sparsely inhabited county was Sutherland, the most densely Lanark. The counties in which there was the largest increase in the decennial period—Ayr, Fife, East Lothian, Argyll and 11 others—belonged largely to the central plain, or Lowlands, in which, broadly stated, industries and manufactures, trade, commerce and agriculture, and educational facilities have attained their highest development. Actually by far the largest increase (35%) was in Bute, but this was only an apparent and not a real increase, because of the number of summer visitors at the time the census was taken.

In every county the population increased between 1801 and 1841. The urban population (*i.e.*, that of burghs and special lighting and scavenging districts with populations of 1,000 and over) was 77·3% in 1921, as compared with 75·4% in 1911. Urbanization is highest in the lowland industrial areas, Lanark, Midlothian and Renfrew having an urban population of over 90%. The highest proportion of rural population is found in Ross and Cromarty (83·7), Orkney (77·8), Berwick (76·4), and Shetland (74·8). The population of the 176 inhabited islands is 154,624.

The burghs in which the largest proportion of Scottish-born persons lived (over 93%) in 1921 were Kirkcaldy, Aberdeen, Dundee, Perth, and Kilmarnock. The largest proportion of English-born were found in Dunfermline and Edinburgh, and Irish-born, in Port Glasgow, Greenock and Coatbridge. There were 20,223 foreigners. In 1926 there were 102,449 births and 63,780 deaths. The birth-rate, which was 29·5 per thousand of the population in 1901, has fallen every year since, with the exception of 1920 and 1921, when it rose to 28 and 25 per thousand. In 1926 it was 20·9. The death-rate also fell from 1901, when it was 17·8 per thousand, until in 1918 it was 16 and in 1926 13·00, the latter being the lowest figure on record, with the exception of that for 1923 (12·9). The marriage rate has remained roughly stationary at 6 or 7 per thousand, except in 1919 and 1920, when it rose to 9. The mortality of infants under one year of age had fallen to 83 per thousand births by 1926. Illegitimate births were 6·8 per hundred. These figures may be compared with those of 1855, when the birth-rate was 31 per thousand of the population, the death-rate 20·8, the marriage-rate 6·6, illegitimacy 7·8, and infant mortality 125 (per thousand births).

Of the total population of Scotland, 91·4% were Scottish in 1921, a figure which had been almost stationary for a considerable period before that date. English people represented 3·8%, Irish 3·2, Welsh 0·1, British Colonials 0·4, British born abroad 0·1, and aliens 0·4. The Irish (159,000 in 1921) and English (who increased by 17·2% between 1911 and 1921) are found mostly in the cities of the south and in the central industrial area; there are very few in the northern counties. In 1921 nearly 170,000 men were employed respectively in agriculture and transport, over 150,000 in mining and quarrying, and 280,000 in metal working. Professional occupations engaged 42,000. Among the women nearly 170,000 were engaged in personal service, and 146,000 in the manufacture of textiles, textile goods and clothes.

In 1931, of the total population 7,069 persons spoke Gaelic only, and 130,080 persons spoke both Gaelic and English. The highest percentages of Gaelic-speaking inhabitants were found in Ross and Cromarty (55), Sutherland (42·2), Inverness (42·1), and Argyll (33·7). In 21 counties under 1% spoke Gaelic, and over 50% of all those speaking the language were found in Ross and Cromarty and Inverness. Of the 73,602 inhabitants of the insular portions of Inverness, Ross and Cromarty and Argyll, 8,797 in 1921 spoke Gaelic only, as compared with 15,746 in 1911; the majority are children under nine or people over 50, Gaelic being still largely the language of the homes.

In recent years, large numbers of Scottish people have emigrated, owing to difficult economic conditions in the rural and isolated areas (from which a large proportion of the emigrants are drawn) and to the prevalence of unemployment in the industrial centres. In 1924 and 1925 Scottish emigrants numbered between one-third and one-half of the number emigrating from England and Wales, although the total population of Scotland is only about one-eighth of that of England and Wales. The population of Canada was 13% Scottish in 1921. This coincides with a large immigration of Irish labourers, which has caused some alarm to certain Scotch writers, as threatening the national traditions of Scotland.

Religion.—The Church of Scotland (Presbyterian) is the most influential and powerful religious body in Scotland, and its membership has increased during the last 50 years at a greater rate than that of the population in general. Nearly half the total marriages of Scotland are performed by Church of Scotland ministers, and there were some 760,000 communicants in 1927. The next most important body is the United Free Church, formed in 1900 by the union of the Free Presbyterian Churches of Scotland. The Church of Scotland Act (1921) was passed in order to facilitate union among the various Presbyterian bodies in Scotland, and the Church of Scotland bill of 1925 vested all the property and endowments of the Church in its general trustees. The Episcopal Church in Scotland had some 145,000 members (60,000 communicants) in 1925, with seven bishops and 352 clergy. There are also smaller bodies of Baptists, Congregationalists, Wesleyan Methodists and Unitarians.

There has always remained a small but steady native Roman Catholic population in Scotland, mostly centred in Inverness and Dumfries, but in recent times the infiltration of Irish labourers has resulted in a large increase in the Roman Catholic population, which was estimated at as high a figure as 606,650 in 1927. There are two Roman Catholic archbishops, four bishops, and one bishop auxiliary, and 13·6% of Scottish marriages are celebrated in Roman Catholic churches. There were over 500 Roman Catholic priests and monks in Scotland in 1921.

(O. J. R. H.)

GOVERNMENT

Parliamentary Representation.—By the Act of Union in 1707 the Scottish parliament was assimilated to that of England. Scottish representation in the parliament of Great Britain was fixed at 16 peers (to the 108 who formed the English House of Lords), to be elected for the duration of each parliament by the peers of Scotland, and 45 members (to the 513 English) in the House of Commons, of whom the Scottish counties returned 30 and the burghs 15. The power of the sovereign to create new Scottish peerages lapsed at the Union. The representation in the Lords has remained unchanged, but the Representation of the People (Scotland) Act of 1832 raised the number of members in the Commons to 53, the counties under a slightly altered arrangement returning 30 as before, and the burghs reinforced by the creation of certain new "parliamentary burghs," 23. The Act of 1867 added 7 members, the universities obtaining representation by two members, while two additional members were assigned to the counties and three to the burghs, and in 1885 the Redistribution of Seats Act gave an additional 7 members to the counties and 5 to the burghs. Under the Act of 1918 the total representation was raised to 74—38 members for the counties, 33 for the burghs and 3 for the universities of St. Andrews, Glasgow, Aberdeen and Edinburgh. Among the counties, Angus,[1] Argyll, Banff, Dunbarton, Dumfries and West Lothian return one member each; Fife and Renfrew, two members each; Lanarkshire 7 members (in the divisions of Bothwell, Coatbridge, Hamilton, Lanark, Motherwell, Northern and Rutherglen). The combined counties of Berwick and East Lothian, Caithness and Sutherland, Moray and Nairn, Orkney and Zetland, Roxburgh and Selkirk, and Galloway (the shire of Wigton and stewartry of Kircudbright combine to form the parliamentary county and sheriffdom of Galloway) return one member for each two counties; Midlothian and Peebles, Perth and Kinross, Stirling and Clackmannan, two for each two counties; Aberdeen and Kincardine, Ayr and Bute (including the division of Kilmarnock), Inverness with Ross and Cromarty (including the Western Isles division), three members for each two counties. While a majority of the burghs are included for parliamentary purposes in the counties in which they are situated,[2] the following form independent constituencies, namely, Greenock, Leith, Paisley, one member each; Aberdeen and Dundee, two members each; Edinburgh, 5; Glasgow, 15 (in the divisions of Bridgeton, Camlachie, Cathcart, Central, Gorbals, Govan, Hillhead, Kelvingrove, Maryhill, Partick, Pollok, St. Rollox, Shettleston, Springburn and Tradeston). Six groups or "districts of burghs," named after the leading burgh in each group, also return one member each, namely, Ayr, Dumbarton, Dunfermline, Kirkcaldy, Montrose, and Stirling and Falkirk districts of burghs.

The Central Authority.—The minister for Scottish affairs is the secretary of State for Scotland. This office came into existence at the Union but was abolished in 1746. From 1782 to 1885 Scottish business was entrusted to the Home Department (afterwards the Home Office) advised by the lord advocate, the

[1] By a resolution of the county council in May 1928 the county reverted to its older historic name of Angus in place of Forfarshire. Other instances of shire names derived from the county town giving place to the older name are the three Lothians, East, West and Midlothian, for Haddingtonshire, Linlithgowshire and Edinburghshire, and Moray for Elginshire. Dunbarton and Zetland are the Scottish forms for Dumbartonshire and Shetland.

[2] Twenty-three counties include all burghs within their area for parliamentary purposes.

chief Scottish law officer. The office of secretary for Scotland was restored in 1885, and in 1894 the Local Government Board for Scotland was established; in 1926 the secretaryship for Scotland was raised to a principal secretaryship of State with a seat in the cabinet. The department for Scottish affairs is the Scottish Office. The secretary for Scotland is the responsible head of the other departments by which Scottish business is administered, and he is assisted by the lord advocate and the solicitor general for Scotland, both of whom are members of the Government though not in the cabinet, and by the parliamentary and permanent under-secretaries. Official publication of Scottish business is made in the *Edinburgh Gazette*. The other Scottish departments, each with its permanent secretary and offices in Edinburgh, are the Scottish Board of Health, which succeeded in 1919 to the former Local Government Board for Scotland; the General Board of Control (Scotland), which was constituted as a Board of Lunacy in 1857; the Scottish Education Department; the Board of Agriculture for Scotland; and the Fishery Board for Scotland. There is also a Scottish Valuation Office in Edinburgh under the administration of the Board of Inland Revenue for the United Kingdom. The Scottish Board of Health is the department concerned with local government. There are, however, no Scottish departments to answer for the functions and policy exercised by the Home Office, the Board of Trade and the Ministries of Transport, Labour and Pensions (*see* GOVERNMENT DEPARTMENTS) in respect to mines, emigration, electricity supply, roads and canals, unemployment, etc. The Scottish Office and the Scottish Education Department have offices in London, and the last named being a committee of the privy council, the lord president of the council signs the annual report as *ex officio* head of the department. The Scottish departments are also assisted by advisory committees or councils, such as the Highlands and Islands Consultative Council for the 7 northern counties constituted under the Scottish Board of Health Act of 1919. By the Reorganization of Offices (Scotland) Act 1928, the Scottish Boards of Health and Agriculture and the prison commissioners for Scotland become departments as from Jan. 1929; the main effect of this is that they are under a single advisor instead of a group or board. Other Scottish officers are the keeper of the registers and records and the registrar-general.

LOCAL GOVERNMENT

Local government administration in Scotland follows the same general principles as in England. (*See* LOCAL GOVERNMENT.) But there are no urban or rural district councils in Scotland, poor relief is administered throughout by the parish councils, and education is entrusted to an *ad hoc* education authority for the county in place of the town, county and urban district councils in England. Public general Acts are sometimes modified, or their terms may be expressly excepted, with reference to their application in Scotland; local authorities are held to have more independent powers for raising loans and a simpler legal procedure for private bill legislation. On the whole, it is said, "independent powers have been more freely entrusted to small municipalities in Scotland than in England." Other differences are the levying of rates on both owner and occupier in Scotland; the election by town councils of their own magistrates or bailies for the burgh, as well as the closer relations to local bodies and wider administrative and judicial functions of the sheriffs.

Local Government Units.—The principal divisions of local government administration are the county, burgh and parish councils, with the education authorities already named. In addition, the following statutory bodies, mainly appointed by the county councils, may be named: the county district committees are the executive body of the council in each of the electoral divisions in which they are elected; the standing joint committee of the county is responsible for police administration and has control over all loans and capital expenditure; the county road board is the authority for road and bridge construction (maintenance and administration lie with the district committees); and district boards of control for counties and combined counties (with representatives of parish councils and royal and parliamentary burghs) deal with lunacy under the General Board for the country. The total number of these authorities is thus: the 33 county councils with their respective standing joint committees, county road boards and education authorities (Edinburgh, Glasgow, Dundee and Aberdeen are separate education authorities), and 27 district boards of control and 98 district committees; 201 burgh or town councils and 869 parish councils. There are 61 police districts, consisting of the 33 county and 28 burghal police districts. In addition, there are a number of statutory committees for particular purposes, such as finance, pensions, distress (unemployment), school management, health insurance, etc., committees, as well as joint committees of local bodies for purposes in which they are jointly interested, and special district committees for water supply, light, scavenging and drainage. About three-fourths of the population is "burghal," the remainder "landward": terms used in Scotland to denote urban and rural. Twenty-two burghs have a population of over 20,000; 8 counties have less than 10,000 population and 5 have a smaller population than in 1801. Of the parishes, 653 are landward; 210 are partly landward, partly burghal.

County, burgh and parish councils are directly elected bodies, and until recently were the three principal authorities for rating and borrowing. By the Rating (Scotland) Act 1926 parish councils ceased to be a rating authority. The chairmen of town and county councils are *ex officio* justices of the peace; the chairman of a town council is called the provost, or in some cases the lord provost; other chairmen in Scotland are called conveners.

Police and Other Powers.—Under the Local Government (Scotland) Act which set up the new county councils in 1889, royal and parliamentary burghs were excluded from the administrative county area. But a limiting condition as to population frequently applies in respect of certain duties and powers. Since 1892 a population of 20,000 is required for any new burgh wishing to maintain a separate police force, and for all burghs appointing a quota to the county insurance committee under the National Health Insurance Act. Any burgh may, however, consolidate its police establishment with that of the county and with royal and parliamentary burghs that do not maintain their own police are represented on the county council by a member or members of the town council, but voting only in respect of such delegated or excepted powers. Police burghs, though self-governing units for public health purposes, and in some cases including highways and police administration, are included in the county area for general county purposes.

Valuation and Assessment.—The word assessment is used in Scotland for rate in England, and the word valuation for what in England would be called assessment. Valuation rolls in Scotland are made up annually. By the Rating (Scotland) Act 1926, which came into force on May 16, 1927, parish councils ceased to be rating authorities, and there is thus only one rating authority for all rates leviable in any rating area, namely, either the town or county council. The amounts to be provided for each of the purposes administered by parish councils are certified by them to the rating authority, who fixes the rate or "assessment" per £.

County and parish rates are levied equally on owners and occupiers; in burghs about two-thirds of the aggregate sum raised by rates fall on occupiers and one-third on owners. Education authorities, district committees and district boards of control requisition for the sums they require by precept on the rating authority. Inequalities in the basis of rating, especially in respect of land held out of use and, on the vast scale which is peculiar to Scotland, for sporting purposes (*see* Report of the Scottish Land Enquiry Committee), have led to the promotion of a number of bills aiming at the reform of local taxation. Thus in 1904 the Land Values Taxation (Scotland) Bill, known as the "Glasgow Bill," gave effect to the principle of rating based on the site or capital selling value of the land, apart from improvements, and led in 1907–08 to a Government Land Values (Scotland) Bill, which however dealt with valuation and not with rating, and like other subsequent private members' bills failed to become law. (*See* TAXATION, LOCAL.)

The Common Good.—A feature of burgh accounts which is

peculiar to Scotland is the property known as the Common Good which is held by certain burghs for the benefit of the community. Originating in grants of land or the accumulated surpluses of feu duties, markets or other assets, the proceeds of the Common Good may be expended for any object directly beneficial to the community without the statutory restrictions that apply to the ordinary grant and rate income. Thus, the small town of Tain (pop. 1,551) with a rateable value of £10,479 in 1927 had a Common Good producing over £800 a year and Kirkcudbright one of £1,500 a year, whilst in Glasgow the city tramways have been largely constructed with the monies and loans raised on the security of the Common Good, to which in return contributions from the tramways aggregating over a million pounds sterling had been made in 1926.

Local Government (Scotland) Act (1929).—The Scottish bill goes much farther than the English Act, to which it is generally similar, in the proposal to abolish a large number of existing local authorities, with other changes in the character and constitution of the new bodies.

Administrative Changes (Part I).—The Act makes a new classification of all burghs into "large burghs," containing a population of 20,000 or over, and "small burghs," meaning all other burghs. The administrative county will include all small burghs, and the reconstituted county councils and town councils of large burghs will become the local authorities for poor law, major public health services, town planning, maintenance of classified roads, police, valuation, and lunacy and mental deficiency. All large burghs which do not maintain a separate police at present will be included for police purposes in the county. Police burghs will cease to be electoral divisions of the county and (as in the case of royal and parliamentary burghs at present) will nominate representatives to the county councils with voting power in respect of those services in which they are interested. County councils may delegate some of their functions with regard to classified roads to the small burghs, who will continue to administer their own water supply, drainage and housing services. The following existing authorities are to be abolished: Parish councils, district committees, district boards of control, education authorities, distress committees, standing joint committees, commissioners of supply and (where the county council may require) landward committees. Statutory committees will be appointed for police, poor relief and education. The education area will be the county as before, but the duties of the former *ad hoc* authorities will be transferred to the education committees. Six groups of burghs are named that are to be compulsorily united, and the counties of Kinross and Perth, Moray and Nairn, and Bute with Renfrew and Ayr, are to be combined for administrative purposes. The new county and town councils (1929) will prepare and submit schemes to the Scottish secretary for his approval of the administrative arrangements proposed to be made throughout their areas for all the changes to be effected. County councils may be required to divide the county (except for education) into areas to be administered by local committees or sub-committees. Town and county councils are to be put on the same basis of audit. Rates are to be consolidated over the whole area of the rating authority, except in the case of differential rating for special parish and special district rates. Payment of travelling expenses and allowances to members of the county councils and committees and sub-committees attending meetings is introduced.

An important new provision (s. 12) authorizes the co-option of non-elected persons to any committee or sub-committee of a town or county council (other than an education or school management committee under s. 3 of the 1918 Act) to an extent not exceeding one-half of the members, and the first poor relief and education committees to be appointed must include one or more members of the outgoing bodies. Education committees must provide for a majority of the members of the council, the inclusion of women, and the appointment of persons of experience in education and in the needs of the area, including in all cases at least one person "conversant with the custom which has prevailed in the public schools of Scotland of giving instruction in religion to children whose parents do not object to the instruction so given," and including also in the case of any "transferred" or denominational school at least one representative of the church or denominational body. The derating and exchequer grant clauses in the Scottish Act are similar to those in the English Act. (*See* LOCAL GOVERNMENT IN ENGLAND AND WALES and IRELAND, NORTHERN.)

SOCIAL AND ECONOMIC CONDITIONS

Poor Relief.—Before the Reformation, relief of the poor had been the duty of the Church, for early legislation aimed at suppressing rather than aiding poverty. Those who were absolutely dependent on alms might receive a licence to beg within the bounds of their own parish, but the able-bodied poor were severely dealt with. The act of 1579 directed the magistrates in towns and the justices in rural parishes to prepare a register of the aged and impotent poor and to levy a tax on the inhabitants of every parish for their support. One consequence of the denial of relief to the able-bodied was that the workhouse of the English poor-law system was not established in Scotland, though almshouses are found in many towns, and poorhouses, where those indigent who are alone in the world without any one to care for them find food and shelter, began to be general in the 19th century. Hence arises the prevalence of out-relief, one of the distinctive features of the Scottish poor law. The act of 1579, however, proved largely inoperative, and even in 1842 about half of the parishes were yet unassessed to the poor. The inadequacy of the voluntary system to cope with genuine distress, in respect both of contributions and of the dispensing of alms, led in 1845 to the passing of an Act which made the parish the poor-relief area, substituted the parochial board for the kirk-session where recourse was had to a rate, made the appointment of inspectors of the poor and medical officers compulsory, and set up a system of central administrative control known as the Board of Supervision for the Relief of the Poor. In 1894 a change in the governing body was effected, the Local Government Board for Scotland replacing the Board of Supervision, while the parochial boards made way for parish councils. As the authorities could not give relief to those able to work, there were no casual wards in Scotland, vagrants having to pay for their night's lodging, or find it in the police station or elsewhere, but this was altered in 1922. A Scottish Board of Health (now the Department of Health for Scotland) was created in 1919, and took over the powers and duties of the Local Government Board, the Scottish Insurance Commissioners, etc. It was entrusted with all measures concerning the health of the people, including the supervision of local housing schemes under the Housing (Scotland) Act of 1919. The district lunacy boards (practically joint-committees of the county and burgh councils) were reconstituted in 1913 as a General Board of Control, charged with the upkeep of mental hospitals, the poor-law authorities defraying only the maintenance of their own patients.

For the extensive changes in the administration of public assistance effected by the Local Government Act, 1929, *see* POOR LAW. Responsibility for the general administration of relief, and for the provision, maintenance and management of all public institutions for the cure of disease was placed on the county and county borough authorities.

Police.—It was not till the middle of the 19th century that a regular police force was established in Scotland. Till then dwellers in rural districts had practically to provide for their own safety as best they could, while some towns maintained a

paid watch and others enrolled volunteer constables, every citizen being expected to take his turn in patrolling the streets to protect person and property. At first an adoptive Act was introduced, under which the commissioners of supply, who then managed county business—resident landowners in possession of landed estate to the annual value of £100—were empowered to raise a police force in the counties; but the want of common policy and initiative led in 1857 to the compulsory institution of a police force throughout the country. Burghs having a population of more than 7,000 might furnish their own police, and smaller burghs were policed as part of the county to which they belonged.

The police forces, of which there were 31 county and 27 city and burgh in 1927 (excluding Orkney and Shetland which do not come under the Act of 1857) are paid for partly from the county rates and partly by Government subsidies.

Education. (*a*) *Elementary Schools.*—The system of schools which prevailed till the Education Act of 1872 dated from 1696, when the Act of Settling of Schools was passed—one of the last but not the least of the achievements of the Scots Parliament—providing for the maintenance of a school in every parish by the kirk-session and heritors, with power to the commissioners of supply to appoint a schoolmaster in case the primary authorities made default. The schoolmaster held his office for life, co-education was the rule, and the school was undenominational. The various religious secessions in Scotland led to the founding of a large number of sectarian and subscription schools, and at the Disruption in 1843 the Free Church made provision for the secular as well as the religious instruction of the children of its members. The Education Act of 1872 abolished the old management of the parish schools and provided for the creation of districts (burgh, parish or group of parishes) under the control of school boards, elected every three years by the ratepayers. School fees for the compulsory standards were abolished in 1889. The Education (Scotland) Act, which accompanied the English Act of 1918, brought great educational changes. The school boards were swept away in favour of larger administrative areas. The counties, with the exception of Edinburgh, Leith (now incorporated with Edinburgh), Glasgow, Aberdeen and Dundee, were made separate educational areas. The educational authorities, who are elected by the local government electors, expend the Education Fund, which is raised from Government grants or loaned and from local rates. Expenditure or education has grown enormously, owing to the operation of the Act and to a large increase in teachers' salaries.

(*b*) *Secondary Schools.*—Records of the existence of schools in the chief towns occur as early as the 13th century. They were under the supervision of the chancellor of each diocese, and were mainly devoted to studies preparatory for the Church. Before the Reformation schools for general education were attached to many religious houses, and in 1496 the first Scottish Act was passed requiring substantial householders to send their eldest sons to school from the time they were eight or nine years old until they were "competentlie founded and have perfite Latin." In 1560 John Knox propounded in his *First Book of Discipline* a comprehensive scheme of education from elementary to university, but neither this proposal nor a School Act passed by the privy council in 1616 for the establishment of a school in every parish was carried into effect. In several burghs grammar schools have existed from a very early date, and some of them, as the Royal High School of Edinburgh and the High School of Glasgow reached a high standard of proficiency. They were largely supported by the town councils, who erected the buildings, kept them in repair, and usually paid the rector's salary. By the Act of 1872 their management was transferred to the school boards. There were in 1928, 252 secondary schools, including higher-class public schools, such as the old grammar schools and the liberally endowed schools of the Merchant Company in Edinburgh. In 1885 the Scottish Education Department was reorganized. It was separated from the English Department, and undertook the inspection of higher class schools (public, endowed and voluntary), and two years later instituted a leaving certificate examination, the pass of which is accepted for most of the university and professional authorities in lieu of their preliminary examinations. In 1923 new regulations were made for secondary schools. A Technical Schools Act, passed in 1887, was applied by a few local authorities; but in 1890 funds were by chance made available from an unexpected source, and devoted to the purposes of technical and secondary education. Parliament had introduced a measure of public-house reform along with a scheme for compensating such houses as lost their licences. This feature was so stoutly opposed that the bill did not pass, although the chancellor of the exchequer had provided the necessary funds. Government proposed to distribute this money among local authorities and expend the balance in relief of rates, but a clause was inserted in this bill giving burgh and county councils the option of spending the balance on technical education as well as in relief of rates. Advantage was largely taken of this power, and the grant came to be succinctly described as the "residue" grant. There were in 1928 11 Central Institutions under the Scottish Education Department and 5 under the Department of Agriculture for Scotland, including the Glasgow Veterinary College, which is not in receipt of a government grant. Among the more important are the Heriot-Watt College, Edinburgh; the Royal Technical College, Glasgow; the West of Scotland Agricultural College; the Edinburgh and East of Scotland Agricultural College; Robert Gordon's Technical College, Aberdeen; and the Dundee Technical College. A new system of continuation classes was brought in under the 1918 Act, and nearly a thousand classes were in existence in 1928.

The leading public schools on the English model are Trinity College, Glenalmond, Perthshire; Loretto School, Musselburgh, and Fettes College, Merchiston College and the Academy in Edinburgh.

(*c*) *Universities and Colleges.*—There are four universities in Scotland, namely (in the order of foundation), St. Andrews (1411), Glasgow (1450), Aberdeen (1494) and Edinburgh (1583), in which are the customary faculties of arts, divinity, law, medicine and science. In 1901 Andrew Carnegie gave £2,000,000 to the universities. The administration of the fund was handed over to a body of trustees, who devote the annual income partly to the payment of students' fees and partly to buildings, apparatus, professorships and research. State financial assistance to the universities has been very largely increased since the Education Act of 1918, and a number of new chairs have been founded by private benefactions, and from further grants by the Carnegie trustees.

The court of each university is the supreme authority in regard to finance, discipline, and the regulation of the duties of professors and lecturers. The universities are empowered to affiliate other academical institutions, and women students are admitted on an equal footing with men. Under the Act of 1899 the University College of Dundee was incorporated with St. Andrews University, and Queen Margaret College became a part of the University of Glasgow; the buildings and endowments, used for women students exclusively, being handed over to the University Court. St. Mungo's College, Glasgow, incorporated in 1889 under a Board of Trade licence, has a medical faculty, and Anderson's College Medical School, Glasgow, was instituted in 1887. These are on the same basis as the extra-mural medical schools in Edinburgh, their medical curricula qualifying for licence only and not for Scottish university degrees. The United Free Church maintains colleges at Aberdeen, Edinburgh and Glasgow, and there are Roman Catholic colleges at Blairs near Aberdeen and at Glasgow, besides a monastery and college at Fort Augustus, and Episcopal, Baptist and Congregational colleges. The Episcopal Church and the Roman Catholic Church have training colleges for teachers.

Agriculture.—Though Scotland still contains many great estates, this circumstance possesses less significance from the agricultural than from the historical standpoint. The excessive size of the properties may to some extent be accounted for by the fact that most of the surface is so mountainous and unproductive as to be unsuitable for division into smaller estates, but two other causes have also operated, namely, first, the wide territorial authority of

such Lowland families as the Scotts and Douglases, and such Highland clans as the Campbells of Argyll and Breadalbane, and the Murrays of Athol and the duke of Sutherland; and secondly, the stricter law of entail introduced in 1685. Thus many of the largest estates remain in the hands of the old hereditary families, but since the World War a large number have been sold. The proportion of persons farming their own land has become much greater and is still increasing. The almost absolute power formerly wielded by the landlords, who within their own territories were lords of regality, hindered independent agricultural enterprise, and it was not till after the abolition of hereditable jurisdictions in 1748 that agriculture made real progress. The Society of Improvers in the Knowledge of Agriculture, founded in 1723, ceased to exist after the rebellion of 1745, and the introduction of new and improved methods, where not the result of private energy and sagacity, was chiefly due to the Highland and Agricultural Society, established in 1784. Further stimulus was also supplied by the high prices that obtained during the Napoleonic wars. The system of 19 years' leases had proved distinctly superior to the system of yearly tenancy so general in England, although prejudicially affected by customs and conditions which, for a considerable time, seriously strained the relations between landlord and tenant. But the abolition of the law of hypothec in 1879—under which the landlord had a lien for rent upon the produce of the land, the cattle and sheep fed on it, and the live stock and implements used in husbandry—the Ground Game Act of 1880, the several Agricultural Holdings Acts, and the construction of light railways improved matters and established a better understanding. The period of general depression which set in before 1885 was surmounted in Scotland with comparatively little trouble. A large amount of capital was lost by tenants, and a few farms were thrown here and there upon the landlords' hands, but in no district was rent extinguished or were holdings abandoned. The sub-commissioners who reported to the Royal Commission on Agriculture in 1895 found nearly everywhere a demand, sometimes competition for farms, persisting throughout the crisis. Afterwards, owing to the increased attention given to stock-fattening and dairying, and to a rise in prices, farming reached a condition of equilibrium, and the most noticeable residuum of the period of depression was the large intrusion of the butcher and grazier class into the farmer class proper.

During and after the World War agriculture experienced a period of marked prosperity, giving place to a period of depression in more recent years. The decline in the value of land has been very great.

The crofters of the Highlands and islands had special grievances of their own. During the first half of the 19th century wholesale clearances had been effected in many districts, and the crofters were compelled either to emigrate or to crowd into areas already congested, where, eking out a precarious living by following the fisheries, they led a hard and miserable existence. At last after agitation and discontent had become rife, government appointed a royal commission to inquire into the whole question in 1883. It reported next year, and in 1886 the Crofters' Holding Act was passed. Amending statutes of succeeding years added to the commissioners' powers of fixing fair rents and cancelling arrears, the power of enlarging crofts and common grazings. Since then political agitation has practically died out. In 1911 the Scottish Land Court and Board of Agriculture (now the Department of Agriculture for Scotland) were constituted, and the provisions of the earlier Crofters Acts were extended to other Small Landholders (Scotland) Act. The Department of Agriculture has expended considerable sums in recent years on development, including education and research work. Under the Congested Districts (Scotland) Act of 1897, £35,000 a year was devoted within certain districts of Argyll, Inverness, Ross and Cromarty, Sutherland, Caithness, Orkney and Shetland, to assisting migration, improving the breeds of live stock, building piers and boat-slips, making roads and bridges, developing home industries, etc.

In 1927 there were 16,787 holdings under 5 acres in extent, and 50,340 under 50 acres. Holdings under 50 acres constituted two-thirds of the total, though the larger portion of cultivated land was held in farms between 50 and 300 acres. There were 603 holdings of mountain and heath land only. The average holding in 1927 was 61·7 acres. The total number of holdings has fallen during the last 40 years, there being fewer small and very large holdings, while the number of medium-sized farms remains fairly constant.

The following table shows the cultivated area and the area under grain, green and miscellaneous crops.

Acreage Under Cultivation

Total area, excluding water, 19,069,683 acres

Crops	Average 1917–26	1927
	Acres	Acres
Total area under crops and grasses	4,732,114	4,681,221
Permanent pasture . .	..	..
For hay	.	167,212
Not for hay	.	1,345,385
Total	1,403,608	1,512,597
Arable land	3,328,506	3,168,624
Grain crops—		
Wheat . . .	61,494	66,577
Barley	160,329	117,369
Oats	1,021,800	897,370
Rye	5,945	3,868
Beans	4,842	3,574
Peas	427	422
Mixed grain	1,678	1,240
Total	1,256,346	1,090,420
Potatoes	150,479	147,184
Turnips and swedes . . .	407,965	376,693
Mangolds	1,819	1,124
Cabbage	3,839	4,197
Rape	11,199	12,916
Sugar beet	..	10,352
Other crops	11,683	11,809
Total	586,984	564,275

During the last half-century the total acreage under crops and grass has remained comparatively stationary, but the acreage under crops has diminished, while land under permanent pasture has increased. Only a little more than one-fourth of the total area of Scotland is cultivated; but it should be borne in mind that permanent pasture does not include the mountainous districts, which not only form a large proportion of the surface, but also, in their heaths and natural grasses, supply a scanty herbage for sheep and cattle, 9,896,854 ac. being used for grazing in 1927. Since 1914 mountain and heath land thus used has increased by 750,000 ac., but the size of this figure is partly due to the inclusion of land previously used as deer forest. Oats remain the staple grain crop, but the acreage of arable land, as also that of land under oats, turnips and barley was in each case the smallest on record in 1927, and considerably below the average of the previous ten years. The areas under wheat and potatoes have, however, increased in recent years, and the acreage of sugar beet, stimulated by a government subsidy, grew from 4 in 1923 to 10,352 in 1927. In the same year there were 1,496,363 ac. under rye grass and other rotation grasses and clover. The yield per acre of grain crops in Scotland is extremely high, as an offset to the limited area cultivated. The average yield of wheat, barley and oats in the ten years from 1917 to 1927 was 39·1, 36·3 and 40·2 bushels respectively.

The following table shows the number of live stock in 1927, with the average for the period 1917–1926. The breeds include the Ayrshire, noted milkers and specially adapted for dairy farms (which prevail in the south-west); Galloway Shorthorns; the polled Angus or Aberdeen, fair milkers, but valuable for their beef-making qualities, and the West Highland or Kyloe breed, a picturesque breed with long horns, shaggy coats and decided colours, that thrives well on wild and healthy pasture. The special breeds of sheep are the fine-woolled of Shetland, the blackfaced of the Highlands, the Cheviots, natives of the hills from which

they are named, a favourite breed in the south, though Border Leicesters and other English breeds, as well as a variety of crosses, are kept for winter feeding on lowland farms. The principal breeds of horses are the Shetland and Highland ponies, and the Clydesdale draught.

Stock	Average 1917–26	1927
Horses—		
Used for agricultural purposes, including mares kept for breeding	137,505	129,526
Unbroken (over 1 year)	32,127	16,778
Unbroken (under 1 year)	10,439	5,671
Total	180,071	151,975
Cattle—		
Cows and heifers in milk or in calf	449,103	460,317
Other cattle, 2 years and above	237,141	225,994
Other cattle, under 2 years	247,322	231,100
Total	933,566	917,411
Sheep—		
Ewes kept for breeding	2,937,817	3,239,143
Other sheep, 1 year and above	1,099,789	1,085,706
Other sheep, under 1 year	2,748,278	3,210,628
Total	6,785,884	7,535,477
Pigs	150,830	196,613

Orchards and Forests.—The acreage devoted to orchards, which was 1,560 in 1880 and 2,482 in 1905, fell to 1,282 in 1927, with 8,064 acres under small fruit. The chief areas for tree and small fruit are Clydesdale and the Carse of Gowrie. Market-gardening has developed in the neighbourhood of the larger towns.

Fisheries.—The Scottish seaboard is divided for administrative purposes into twenty-seven fishery districts, namely, on the east coast, Eyemouth, Leith, Anstruther, Montrose, Stonehaven, Aberdeen, Peterhead, Fraserburgh, Banff, Buckie, Findhorn, Cromarty, Helmsdale, Lybster, Wick (15); on the north, Orkney, Shetland (2); on the west, Stornoway, Barra, Loch Broom, Loch Carron and Skye, Fort William, Campeltown, Inverary, Rothesay, Greenock, Ballantrae (10). The whole of the fisheries are controlled by the Fishery Board for Scotland. In 1928 the number of fishermen directly employed in fishing was 25,943, there were 41,633 engaged in curing and preserving the fish landed and in subsidiary industries on shore, making a total of 66,676 persons engaged in the fisheries and dependent industries. This may be compared with a total of 86,271 in 1913. In 1928 the herring fishery yielded 4,235,567 cwts. The most prolific districts are Shetland in the north, Fraserburgh, Peterhead, Wick in the east, and Stornoway in the west. The principal herring market is continental Europe, Germany being the largest consumer. In 1928 the catch of fish of all kinds (excepting shellfish) amounted to 7,333,218 cwts. The annual value of the shellfish (lobsters, crabs, oysters, mussels, clams, etc.) was £97,974. The weight of salmon carried by Scottish railways and steamers in 1927 was 2,910 ton. In the last few years there has been a steady rise in the salmon catch, and the figure for 1927 was the highest since 1896. There were 7 whalers operating in 1927; 459 whales were caught in 1926, 314 in 1927, and 184 in 1928.

Roads.—In the 12th century an Act was passed providing that the highways between market-towns should be at least 20 ft. broad. Over the principal rivers at this early period there were bridges near the most populous places, as over the Dee near Aberdeen, the Esk at Brechin, the Tay at Perth and the Forth near Stirling. Until the 16th century, however, traffic between distant places was carried on chiefly by pack-horses. The first stage-coach in Scotland was that which ran between Edinburgh and Leith in 1610. In 1658 there was a fortnightly stage-coach between Edinburgh and London, but afterwards it would appear to have been discontinued for many years. Separate Acts enjoining the justices of the peace, and afterwards along with them the commissioners of supply, to take measures for the maintenance of roads were passed in 1617, 1669, 1676 and 1686. These provisions had reference chiefly to what afterwards came to be known as "statute labour roads," intended primarily to supply a means of communication within the several parishes. They were kept in repair by the tenants and cotters, and, when their labour was not sufficient, by the landlords, who were required to "stent" (assess) themselves, customs also being sometimes levied at bridges, ferries and causeways. By separate local Acts the "statute labour" was in many cases replaced by a payment called "conversion money," and the General Roads Act of 1845 made the alteration universal. The Roads and Bridges (Scotland) Act of 1878 entrusted the control of the roads to royal and police burghs and in the counties to road trustees, from whom it was transferred by the Local Government Act of 1889 to county councils. Many of the counties were divided into separately rated districts for road-making purposes, and there were 106 highway authorities in existence in 1928, including 7 burghal authorities. The Local Government (Scotland) Bill of that year, however, was designed to centralize the administration by reducing the authorities to one for each county. The Highlands had good military roads earlier than the rest of the country. The project, begun in 1725 under the direction of General George Wade, took ten years to complete, and the roads were afterwards kept in repair by an annual parliamentary grant. In the Lowlands the main roads were constructed under the Turnpike Acts, the earliest of which was obtained in 1750. As elsewhere in Great Britain, large sums from the Road Fund have been expended in recent years on road-reconstruction and widening and the building of by-pass roads. Work on the Glasgow-Inverness, the Perth-Inverness, and the Glasgow-Edinburgh roads was in progress in 1928. The roads were numbered in 1922.

Canals.—There are four canals in Scotland, the Caledonian, the Crinan, the Forth and Clyde and the Union, of which the Caledonian and Crinan are national property. (*See* CALEDONIAN CANAL.) The Forth and Clyde Navigation (opened in 1790) runs from Bowling on the Clyde, through the north-western part of Glasgow and through Kirkintilloch and Falkirk to Grangemouth on the Forth, a distance of 35 m. There is also a branch, 2¾ m. long, from Stockingfield to Port Dundas in the city of Glasgow, which is continued for the distance of 1 m. to form a junction with the Monkland canal. The reconstruction of the Forth and Clyde Canal to take larger vessels has been much discussed from time to time, but no steps had been taken in the matter by 1929. The Monkland canal (opened in 1792) has a length of 12¼ m., and runs from the north-east of Glasgow through Coatbridge to Woodhall in the parish of Old Monkland. In 1867 both undertakings passed into the hands of the Caledonian Railway Company. The Union canal, 31½ m. long, starts from Port Downie, on the Forth and Clyde canal near Falkirk, and runs to Port Hopetown in Edinburgh. Completed in 1822, it was vested in 1849 in the Edinburgh and Glasgow Railway Company, which in turn was absorbed by the North British Railway Company, and in 1923 by the London and North Eastern Railway. The Aberdeen canal, 18¼ m. long, running up the Don valley from Aberdeen to Inverurie, the Glasgow, Paisley and Johnstone Canal, 11 m. long, and the Forth and Cart Junction canal have been abandoned.

Railways.—The first railway in Scotland for which an Act was obtained was that between Kilmarnock and Troon (9¾ m.), opened in 1812, and worked by horses. A similar railway, of which the chief source of profit was the passenger traffic, was opened between Edinburgh and Dalkeith in 1831, branches being afterwards extended to Leith and Musselburgh. By 1840 the length of the railway lines for which bills were passed was 191¼ m., the capital being £3,122,133. The chief companies were the Caledonian, formed in 1845; the North British, of the same date; the Glasgow and South-Western, formed by amalgamation in 1850; the Highland, formed by amalgamation in 1865; and the Great North of Scotland, 1846. By the Railway Act of 1921 the Caledonian, Glasgow and South-Western, and Highland lines were taken over by the London, Midland and Scottish Company, and the North British and Great North of Scotland by the London and North Eastern Company.

Mining Industry.—Coal and iron, generally found in convenient proximity to each other, are the chief sources of the

mineral wealth of Scotland. The principal coalfields are Lanarkshire, which yields over ⅓ of the total output, Fifeshire, Ayrshire, Stirlingshire and Midlothian, but coal is also mined in the counties (usually reckoned as forming part of one or other of the main fields) of Linlithgow, Haddington, Dumbarton, Clackmannan, Dumfries, Renfrew, Argyll and Peebles, while a small quantity is obtained from the Oolite at Brora in Sutherlandshire. The earliest records concerning coalpits appear to be the charters granted, towards the end of the 12th century, to William Oldbridge of Carriden in Linlithgowshire, and in 1291 to the abbot and convent of Dunfermline conferring the privilege of digging coal in the lands of Pittencrieff. The monks of Newbattle Abbey also dug coal at an early date from surface pits on the banks of the Esk, but it was not used for domestic purposes till about the close of the 16th century. In 1606 an Act was passed binding colliers to perpetual service at the works where they were employed, and they were not fully emancipated till 1799. An Act was passed in 1843 forbidding the employment of children of tender years and women in underground mines. In 1927 there were 502 mines of all kinds in operation, employing 113,061 hands (87,620 below ground). The total output of coal in that year amounted to 34,597,694 tons. The quantity of coal exported in 1927 from the principal Scottish ports was 5,476,722 tons. Since the World War the position in the coal trade has been one of grave difficulty. Between 1913 and 1927 Scotland lost 39 per cent of her foreign trade, and the inland demand was also below normal.

The rise of the iron industry dates from the establishment of the Carron ironworks near Falkirk in 1760, but it was the introduction of railways that gave the production of pig-iron its greatest impetus. In 1865 when the industry was at the height of its prosperity, 1,164,000 tons were produced. In 1927 only 692,100 tons of pig-iron were made. In 1905, 832,388 tons of iron ore were raised but in 1927 only 28,345. The ore came mostly from Linlithgow, Stirling and Dumfries.

The oil shale industry is wholly modern and attained to considerable magnitude after its establishment (in 1851 and following years). Linlithgowshire yields nearly three-fourths of the total output and Midlothian nearly one-fourth. The mineral is chiefly obtained from seams in the Calciferous Sandstone at the base of the Carboniferous rocks. The total production in 1927 was 2,047,263 tons. In the previous four years production had fallen by nearly 800,000 tons Stirling. Better results were hoped for in 1928, as a result of improved refining methods.

Fire-clay is produced in Lanarkshire, which yields between ¼ and ⅓ of the total output, Stirling (nearly ⅓), and, less extensively, in Fifeshire, Ayr, Dumbarton, Linlithgow and a few other shires. With the exception of the counties of Orkney, Shetland and Caithness, granite is quarried in every shire in Scotland, but chiefly in Aberdeenshire, Midlothian, Ayr, Fife and Lanark; limestone is quarried in half of the counties, but especially in Midlothian and Fife; large quantities of paving-stones are exported from Caithness and Forfarshire, and there are extensive slate quarries at Ballachulish and other places in Argyllshire, which furnishes about three-fourths of the total supply. Sandstone, of which the total production in 1927 was 251,715 tons, is quarried in nearly every county, but particularly in the shires of Lanark and Dumfries. Lead ore occurs at Wanlockhead in Dumfriesshire and Leadhills in Lanarkshire. In 1927 there were produced 4,352 tons of dressed lead ore. A small quantity of zinc is mined in Dumfriesshire: over 24,000 tons of barytes were raised in Ayr in 1927, and nearly 48,000 tons of ganister, largely in Stirling. The precious metals were once worked at Abington in Lanarkshire and in the Ochils. Schemes for the utilization of water-power are in operation at Foyers (where alumina is treated) and Loch Leven, and in process of construction in the Lochaber district (1928).

Iron and Steel.—In 1921 35,167 persons were engaged in working of the raw material, in steel smelting and founding, blast furnaces for pig-iron, etc. All the great iron foundries and engineering works are situated in the Central Lowlands, in close proximity to the shipbuilding yards and coalfields, especially in the lower and part of the middle wards of Lanarkshire, in certain districts of Ayrshire and Renfrewshire, at and near Dumbarton, in south Stirlingshire and in some parts of East and Midlothian and Fife. Since the World War the iron industry has reached a condition of stagnation, and in 1928 only 21 of the blast furnaces in existence were at work. The electrical industry, on the other hand, has largely increased in importance, and employed in its various ramifications some 2,000,000 workers in 1928. Steel-work manufacturers have been faced with severe competition in recent years, and have been working under great difficulties. In 1921 the number of persons employed in engineering and machine-making (not marine or electrical) was 92,894 (in 1901 it was nearly 119,000). Ship-building and marine engineering employ 125,026. The metal, machinery and allied trades employed in 1921 354,735 persons.

Manufactures. (*a*) *Wool and Worsted.*—Although a company of wool weavers was incorporated by the town council of Edinburgh in 1475, the cloth worn by the wealthier classes down to the beginning of the 17th century was of English or French manufacture, the lower classes wearing "coarse cloth made at home," a custom still prevalent in the remoter districts of the Highlands. A company of Flemings was established in the Canongate (Edinburgh) in 1609 for the manufacture of cloth under the protection of the king, and an English company for the manufacture of woollen fabrics near Haddington in 1681, but the industry for long made little progress. In fact its importance dates from the introduction of machinery in the 19th century. The most important branch of the trade, that of tweeds, first began to attract attention shortly after 1830; it still has its principal seat in the district the Tweed, including Galashiels, Hawick, Innerleithen and Selkirk. Woollens are also manufactured elsewhere, especially at Stirling, Aberdeen, Elgin, Inverness, Stirling, Bannockburn, Dumfries and Paisley. Carpet manufacture has had its principal seat in Kilmarnock since 1817, but is also carried on in Elderslie, Ayr, Glasgow, Stirling and elsewhere. Fingering and many other kinds of woollen yarns are manufactured at Alloa, the headquarters of the industry. In 1921 the number of operatives in the woollen industry amounted to 22,870.

(*b*) *Flax, Hemp and Jute.*—The manufacture of cloth from flax is of very ancient date, and towards the close of the 16th century Scottish linen cloths were largely exported to foreign countries, as well as to England. Regulations in regard to the manufacture were passed in 1641 and 1661. To encourage the trade it was enacted in 1686 that the bodies of all persons, excepting poor tenants and cotters, should be buried in plain linen only, spun and made within the kingdom. The Act was renewed in 1693 and 1695, and in the former year another Act was passed prohibiting the export of lint and permitting its import free of duty. At the time of the Union the annual amount of linen cloth manufactured in Scotland is supposed to have been about 1,500,000 yards. The Union gave a considerable impetus to the manufacture, as did also the establishment of the Board of Manufactures in 1727, which applied an annual sum of £2,650 to its encouragement, and in 1729 established a colony of French Protestants in Edinburgh, on the site of the present Picardy Place, to teach the spinning and weaving of cambric. The counties in which linen is now most largely carried on are Forfar, Perth, Fife, Aberdeen, Renfrew, and Midlothian. Dundee is the principal seat of the manufacture of coarser fabrics, Dunfermline of the table and other finer linens, while Paisley is widely known for its sewing threads. The allied industry of jute is the staple industry of Dundee. In 1921 the operatives in the flax, jute and hemp industry numbered 55,035.

(*c*) *Cotton.*—The first cotton mill was built at Rothesay by an English company in 1779, though Penicuik also lays claim to priority. The Rothesay mill was soon afterwards acquired by David Dale, who also established cotton factories in 1785 at New Lanark, afterwards so closely associated with the socialistic schemes of his son-in-law, Robert Owen. The counties of Lanark and Renfrew are now the principal seats of the industry. The great majority of the cotton factories are concentrated in Glasgow, Paisley and the neighbouring towns, but the industry extends in other districts of the west and is also represented in the counties of Aberdeen and Perth. As compared with England, however, the manufacture has stagnated. The number of hands employed in

1850 was 34,325, in 1901 it was 34,057, and in 1921 (including bleachers, dyers, printers, calenderers, etc.) it was 41,212.

(*d*) *Silk and other Textiles.*—The principal seats of the silk manufacture are Paisley and Glasgow. In 1901 the number employed amounted to 2,424, but in 1921 it was only 680, including those engaged in artificial silk manufacture, an industry which has increased in importance since that date. The weaving of lace curtains has made considerable progress. Hosiery manufactures, a characteristic Border industry, has its chief seat at Hawick. In 1921 34,493 persons were engaged in the production of miscellaneous textiles, such as rope, carpets, lace, etc. The textile industry has been comparatively prosperous in recent years, and the output in 1928 was probably greater than before the World War.

(*e*) *Whisky and Beer.*—Scotland claims a distinctive manufacture in whisky. Though distillation was originally introduced from England, by 1771 large quantities of spirits were already being consigned to the English market. The legal manufacture of whisky was greatly checked in the earlier part of the 19th century by occasional advances in the duty, but after the reduction of 2s. 4¾d. per proof gallon in 1823 the number of licensed distillers rapidly increased, to the discouragement of smuggling and illicit distillation. In 1900 31,798,465 proof gallons were made, but in 1927 only 18,988,437. In that year all but 7 of the distilleries of the United Kingdom were in Scotland, but the number had fallen from 128 in 1923 to 84. The leading distilling counties are Argyll, Banff and Inverness. Brewing is extensively carried on in Edinburgh, whose ales are in high repute, Alloa and elsewhere. The Temperance Act (Scotland), which came into force in 1920, provided for a poll by local authorities in burghs, wards of large burghs, and parishes with reference to the limitation or abolition of liquor licences, or the retention of the existing licences. In the result 60% of the votes were for no change.

(*f*) *Miscellaneous.*—Paper, stationery and printing are industries in which Scotland has always occupied a foremost position. A paper mill was erected in 1675 at Dalry on the Water of Leith in which French operatives were employed to give instruction, with the result, in the words of the proprietors, that "grey and blue paper was produced much finer than ever was done before in the kingdom." Midlothian has never lost the lead then secured. There are paper mills at Penicuik and elsewhere in the vale of the Esk and around Edinburgh and the industry is also conducted near Aberdeen. Stationery is largely manufactured at Glasgow, Aberdeen and Edinburgh. In 1921 the number of persons employed in the paper and stationery industries amounted to 19,953. Ever since it was established early in the 16th century, the Edinburgh press has been renowned for the beauty and excellence of its typography, a large proportion of the books issued by London publishers emanating from the printing works of the Scottish capital. Printing is also extensively carried on in Glasgow. The number of persons engaged in the production of books and kindred occupations amounted in 1921 to 26,919.

The first sugar refinery was erected in 1765 at Greenock, which, despite periodical vicissitudes, has remained the principal seat of the industry. The making of preserves and confectionery flourishes in Dundee. Kirkcaldy is the seat of the oil floor-cloth and linoleum industries, the latter introduced in 1877. The headquarters of the chemicals manufacture are situated in Glasgow and the vicinity, while explosives are chiefly manufactured at Stevenston and elsewhere in Ayrshire, and at certain places on the Argyll coast. Among occupations providing employment for large numbers were trades in connection with building and works of construction and furniture and timber, while transport (including railways, roads, sea, rivers, docks, harbours, etc.) employed 160,218 persons in 1921.

Commerce and Shipping.—The following table between 1855 and 1927 illustrates the development that took place in the shipping trade with foreign countries and British possessions, as well as the expansion of the coasting trade.

Foreign trade has shown rapid growth. In 1755 the imports were worth £464,411, and the exports £535,576. By 1851 the figures were £8,921,108 and £5,016,116. In 1900 they were £38,691,245 and £32,166,561, and in 1927 £80,822,241 and £62,670,566.

Foreign and Coastwise Trade: Tonnage of Vessels.

Year	Coastwise		Foreign		Total	
	Entered	Cleared	Entered	Cleared	Entered	Cleared
1855	1,963,552	2,057,936	668,078	840,150	2,631,630	2,898,086
1900	7,213,574	6,791,959	5,657,200	6,602,545	12,870,774	13,394,504
1927	8,575,156	8,267,694	9,484,068	12,041,955	18,059,224	20,309,649

Though the value of imports into Scotland is less than one-thirteenth of that into England, this does not represent the due proportion of foreign wares used and consumed in Scotland, for the obvious reason that large quantities of goods are brought into the country by rail, nearly all the tea, for example, consumed in Great Britain being imported into London, while several ports have almost a monopoly of certain other imports. The customs revenue rose from £1,965,080 in 1894 to £3,399,141 in 1903.

Chief Ports—1927

Port	Order	Imports and exports of produce of the U. K.	Order	Tonnage of vessels in foreign trade	Order	Tonnage of vessels in coasting trade
Glasgow	1	76,362,693	1	8,844,258	1	3,491,913
Leith	2	25,545,968	3	3,037,054	4	1,299,055
Grangemouth	3	12,915,297	4	1,842,402	5	1,151,713
Dundee	4	10,830,017	6	1,223,727	8	575,700
Aberdeen	5	3,108,167	7	642,031	3	1,301,503
Greenock	6	2,824,590	2	3,305,958	6	1,124,898
Ardrossan	7	1,492,004	9	402,121	2	1,345,655
Methil	8	1,457,093	5	1,291,091	7	1,065,659
Burntisland	9	904,029	8	629,985	9	304,487

Shipbuilding.—Many of the most important improvements in the construction of ships, especially steam vessels, are due to the enterprise and skill of the Clyde shipbuilders, who, from the time of Robert Napier of Shandon who built and engined the first steamers for the Cunard Company, formed in 1840, have enjoyed an unrivalled reputation for the construction of liners. The principal Clyde yards are situated in the Glasgow district (Govan, Scotstoun, Fairfield, Clydebank, Dalmuir), Dumbarton, Port Glasgow and Greenock. At several of the ports on the lower firth, as at Ardrossan and Fairlie, famous for its yachts, the industry is also carried on. On the east coast the leading yards are at Dundee, Peterhead, Fraserburgh and Aberdeen, which, in the days of sailing ships, was renowned for its clippers built for the tea trade. There are yards also at Inverness. After rising to a "peak" year in 1913, shipbuilding fell off during the World War; and since then its fortunes have been fluctuating and uncertain. The industry was fairly active in 1928, but towards the end of the year the unemployment figures were higher than in any other of the basic industries of the country. (O. J. R. H.)

HISTORY

The Kingdom of Scotland was founded in the early years of the 11th century by an amalgamation of four tribal kingdoms—Scots, Picts, British and Angles, two of which, Scots and Picts, had been united at an earlier period. The Scots were an Irish tribe who settled, about the beginning of the 6th century, in the district known later as Argyll; the Angles, in the second half of the same century, colonized what became the Lothians and the counties of Selkirk, Peebles and Roxburgh. The British, who occupied the country between the Solway Firth and the Firth of Clyde, were akin to the Welsh, and were probably driven into north Britain by the Anglo-Saxon invasions in the south. Three, therefore, of the four constituent parts of the historic kingdoms of Scotland date back no farther than the 6th century. The identification of the Picts and Caledonians whom the Romans found in the country in the first centuries of the Christian era has been for generations a subject of controversy. For Scotland in Roman days *see* CALEDONIA, also BRITAIN.

Christian Scotland.—Scottish history is often said to begin with the mission of St. Columba in 563. Columba was an Irishman of noble birth who became a monk and a priest and settled in Iona to undertake the conversion of the portions of North

Britain which were still heathen. Iona belonged to the small kingdom of Dalriada, which had, comparatively recently, been founded by the race to which Columba belonged, and its ruler was his kinsman. The Scots had come from Ireland, a Christian land, and had brought their religion with them, and Christianity had persisted from Roman times, or had been revived, in Strathclyde. In the beginning of the 5th century, St. Ninian had preached in Strathclyde and had sent his disciples to convert Pictland, and it is probable that many of the religious foundations in the north-east of Scotland, generally ascribed to St. Columba, really date from an older missionary effort.[1] Some years before St. Columba landed in Iona, a great Christian teacher, known as St. Kentigern or St. Mungo, was labouring in Strathclyde, and to his mission is traced the foundation of the future city of Glasgow. St. Columba, therefore, cannot be said to have converted Scotland, but he laboured as a missionary in Pictland and he made Iona the centre of Scottish Christianity. In the century succeeding his death in 597, the most important contribution made by Scotland to the history of Great Britain was the direct result of his work—the re-conversion of the North of England to Christianity. A pagan reaction in the second quarter of the 7th century had dethroned the Christian king, Edwin of Northumbria, who ruled from the Humber to the Forth. Edwin's nephew, Oswald, had been educated at Iona, and, when he recovered the kingdom of Northumbria by a victory won in 655, he brought Scottish missionaries to rebuild the shattered fabric of Christianity. The influence of Scotland upon English Christianity was, however, short-lived. There were some differences of method, organization and ritual between the Irish Church and the Roman Church. Oswald's successor, Oswy, declared in favour of Roman custom, and the Scottish missionaries abandoned Northumbria in accordance with the decision of the Synod of Whitby (664).

Picts, Scots and Norse.—The kingdom of Northumbria had, by this date, reached the height of its greatness, and its rulers were ambitious of conquering the north of the island. In 685 a great Northumbrian army invaded Pictland and was defeated at the battle of Nectansmere, fought near Dunnichen in Forfarshire. The expedition proved to be the ruin of Northumbrian supremacy in England; the centre of English power shifted southwards and the menace of an English conquest was removed. North Britain was to be left, for some centuries, to work out its own destiny. The Picts became supreme in the north, and gained control over both the Scots of Dalriada and the British of Strathclyde. Then the Picts were weakened by the attacks of the Norsemen, who first attacked the coasts in the end of the 8th century, and, about 835, began to make permanent settlements. Dalriada threw off Pictish control, and in 844, when the Norsemen were attacking Pictland, Kenneth MacAlpine, King of the Scots, established a claim to the Pictish throne. There seems to have been something in the nature of a conquest, but the resources of Pictland were so much greater than those of Dalriada that it is difficult to credit the smaller country with a military conquest of the larger.

Kenneth MacAlpine's claim was in right of his mother, and the Picts preferred maternal to paternal descent. The union of Picts and Scots was followed by an attempt to snatch the Lothians from Northumbria, then devastated by the Danish invasions; but the effort was unsuccessful, and Kenneth's successors were themselves engaged in struggles with the Norsemen, who occupied the Hebrides and the Orkney and Shetland islands and made settlements along the western and northern coasts and on the east coast as far south as the Moray Firth. They also attacked the kingdom of Strathclyde and founded colonies between the rivers Esk and Dee. The islands became definitely Scandinavian, as also did a large part of Caithness. During the long conflict with the Norsemen, the Scots sometimes allied themselves with the English against the common enemy, and these alliances constituted, long afterwards, a ground of the English claim to the overlordship of Scotland, but there were other occasions upon which the Scots joined the Norsemen against the English.

[1] W. D. Simpson, *The Historical St. Columba* (1927).

Conquest of Lothian.—The most important attempt of the latter kind occurred in 937 when the Scottish king, Constantine III., was defeated by Athelstan of England at Brunanburh (probably Burnswark on the Solway). Constantine's object was the realization of a persistent ambition which is, perhaps, the most remarkable feature of Scottish history in the two centuries following the union of the Picts and Scots—the severance of the Lothians from the kingdom of Northumbria. These attempts continued throughout the 10th century but did not attain any permanent success till, in 1018, Malcolm II. completely defeated the Northumbrians at the battle of Carham, near Coldstream. The victory was followed by the gradual extension of Scottish rule to the Tweed. Malcolm was followed, in 1034, by his grandson, Duncan, who had already succeeded, by inheritance, to the throne of Strathclyde, and thus Scots, Picts, Angles and British were all included within the kingdom which came to be known as Scotland. The Norsemen still held the islands; the Hebrides were not recovered till after the middle of the 13th century, and the Orkneys and Shetlands not till the middle of the 15th century, when they passed from Denmark to Scotland through the marriage of a Danish princess to James III.

ANGLICIZATION AND FEUDALIZATION

Macbeth and Malcolm III.—Duncan, the Duncan of Shakespeare's "Macbeth," the first ruler of the historical kingdom of Scotland, did not experience the "plenteous joys" which brought tears into his eyes in the play. He met with defeats both from the Northumbrians and from the Norsemen, and in 1040 he was slain in a civil war by his own general, Macbeth, who had a claim to the succession, probably in his own right, and also as the representative of his wife and stepson. Macbeth was almost certainly in alliance with the Norwegian earl of Caithness and Sutherland, a cousin of Duncan, named Thorfinn. While Thorfinn lived, attempts to dethrone Macbeth, who proved himself an efficient ruler, were unsuccessful, at all events in Pictland, though Strathclyde and the Lothians may have acknowledged Malcolm Canmore (Bighead) the son of Duncan. After Thorfinn's death, Malcolm, in 1057, defeated and slew Macbeth at Lumphanan in Aberdeenshire. The kingdom of which Malcolm III. took possession was a Celtic kingdom, though one of its provinces was peopled by Angles. Local and tribal custom prevailed alike in Scotland proper (the district north of the Forth and Clyde) and in Galloway; the speech was Celtic; the court and the administrative system, so far as the latter can be said to have existed, were Celtic. The church still retained, to a large extent, the structure and customs of Irish Christianity, although, in the beginning of the 8th century, a powerful Pictish monarch had ordered his people to keep the Roman date for Easter (one of the points disputed at the Synod of Whitby) and this rule had afterwards been followed in Dalriada and probably in Strathclyde. The Irish Church did not repudiate papal authority, but there was no opportunity for the exercise of papal jurisdiction. Diocesan organization did not exist. There was only one bishop of the Scots; his see was St. Andrews and he could enjoy little influence outside his own neighbourhood. Such organization as the Columban Church had originally possessed was based upon powers claimed by the abbots of the monasteries, but the abuse of appointing lay abbots had destroyed the early monasticism, and a later order of monks, the Culdees, which had developed in the 9th century, had no administrative authority.

Queen Margaret.—The disorganized state of the Scottish Church, and some peculiar customs which marked its ritual, shocked the conscience of Malcolm's wife, an English princess, Margaret, who, after the Norman Conquest, sought refuge in Scotland. Margaret was a woman of saintly life—she was canonized a century and a half after her death—and her own desire was to be a nun. She would have been the glory of a cloister, but she accepted her mission to redeem an ignorant and almost schismatic nation. She was not destined to fulfil that mission herself, but its accomplishment was, none the less, her work. There were many difficulties in her way. She could not introduce a diocesan system till there was a vacancy in the one Scottish bishopric, and none

occurred in her lifetime. She could not reform the monastic system and bring it into line with European monasticism, because Malcolm, though amenable in many ways to his wife's influence, refused to surrender the gains which he and other laymen, the great men of the land, enjoyed from the secularization of monastic revenues. She did succeed in changing some Scottish customs. She brought English clergy to convince the Scots of the error of their ways (Malcolm who had been in exile in England, acting as interpreter); she restored the monastery of Iona which had been destroyed by the Northmen; and she encouraged the Culdees as the nearest approach to the religious life which she admired. Her most important personal achievements were the introduction of an English-speaking court and of English-speaking clergy, and the education of her children in English ways and traditions. She bore six sons to Malcolm, but he was not allowed to give any one of them his own name, or the name of any of his predecessors; four of them were named after Saxon kings of England.

Anglicization of the Church.—Margaret's three sons who successively came to the throne had all some personal experience of English life. Malcolm III. and his eldest son, Edward, were killed in 1093 in one of the raids on the north of England from which his pious wife vainly tried to restrain him. After his death there was a Celtic reaction against the Anglicizing influences introduced by Margaret (who was herself dying when her son Edgar brought her the news of the deaths of his father and brother). The English who had followed the queen to Scotland were driven out, and Edgar and his brothers, Alexander and David, took refuge in England. It was with English help that Edgar regained his throne in 1107; he died ten years later and was succeeded by Alexander, and he in turn by David (1124–53). The three brothers were all their mother's sons, and they continued her work. All three were pious and all three were English in tastes and sympathies, and were bent upon converting Celtic Scotland into a feudal kingdom of the Anglo-Norman type. Piety and policy both pointed in one direction; the church was to be one of the most powerful instruments of Anglicization. Edgar abandoned Malcolm's palace at Dunfermline and held an English court at Edinburgh. Alexander suppressed a Celtic rebellion in Moray and Mearns so efficiently that he earned the description "the Fierce," and he followed up his victory by founding a house of Austin Canons at Scone (the coronation place of the Pictish kings and their Scottish successors) and filling it with English monks. The Anglicization of the country, outside the western and northern Highlands, was to a very considerable extent the result of ecclesiastical influences. Alexander I. and David I. planted English monasteries in many districts of Scotland, south of the Moray Firth, and endowed them so liberally that David acquired a popular reputation for sanctity. However, the political motive of the new foundations is indicated by the suppression of the Culdees, the form of religious life associated with the Gaelic speech and with Celtic customs.

The plantation of monasteries was accompanied by a diocesan organization of the church. This was essential for efficient ecclesiastical administration and for the exercise of papal supremacy, but it was also useful as a means of furthering royal policy. The new bishops were English, their sees were richly endowed with lands, and their religious authority was enhanced by their position as territorial magnates. Diocesan organization was delayed by claims asserted by the sees of Canterbury and York to possess superiority over the church in Scotland. Two Englishmen in succession, Turgot, the chaplain and biographer of Queen Margaret, and Eadmer, the ecclesiastical historian, were elected to the see of St. Andrews, but Turgot acknowledged the superiority of York and Eadmer that of Canterbury, and neither was allowed to reside in Scotland. Alexander I. would not tolerate pretensions which, apart from introducing complications into the relations between Church and State, were likely to compromise the independence of the Scottish Crown. Ultimately, on Eadmer's death in 1124, the English prior of the new monastery at Scone was consecrated to the see of St. Andrews by the Archbishop of York, without prejudice either to the claims of York or to the freedom of the Church in Scotland. Under David I. the process of organization went on rapidly, and all the mediaeval Scottish dioceses had been founded by the end of his reign.

Anglicization of the Administrative System.—David I. was more familiar with English ways than any of his brothers. His sister was married to Henry I. and he spent some years of his youth at the English court, made friends with Anglo-Norman barons and married the widow of one of them. He changed the system of land tenure in Scotland by making to his English friends grants of land, on the model of the charters granted by the Anglo-Norman kings of England. The first of the Scottish Bruces, for example, received by charter a grant of over 200,000 acres in Annandale, and the progenitor of the House of Stuart came to Scotland as the recipient of charters conveying great tracts of land in Ayrshire and Renfrewshire. There was no dispossession of the existing landowners; they held their rights, in future, from the new lord instead of directly from the Crown. Such charters were granted not only to newcomers, but also to great landlords who had hitherto held their lands by tribal custom and were glad to receive written guarantees of their possessions and privileges. Gradually, the whole of the land, outside the Highlands, came to be held under feudal law, and the landowners, whether Anglo-Normans or representatives of the old Scottish families (who intermarried with David's new nobility), were, like the monks and the bishops, inevitably instruments of the royal policy of Anglicization. The civil, as well as the ecclesiastical, organization was gradually remodelled in accordance with English (and European) institutions, and, under David and his successors, great officers of the household (whose functions were analogous to the duties of later administrative departments) came into existence, the English office of sheriff was borrowed for purposes of local government, and the old tribal laws of the component parts of the kingdom were replaced by adaptations of English legislative measures. To the influences of an English court, an English Church, and an English system of law and land-tenure were added the effects of English trade. Commerce was mostly with England and from England was adopted the institution of the burgh. The early Scottish burgh charters were all founded on English models, and colonies of English merchants settled in Scottish towns. These processes, initiated under the sons of Queen Margaret, had a continuous development until the outbreak of the War of Independence. A series of Celtic revolts against the Anglicizing policy of the Crown occurred in the course of the 12th century and in the beginning of the 13th, but they were all suppressed (sometimes with English help), and, before the death of Alexander III. in 1286, the organization of Lowland Scotland, from the Moray Firth to Tweed and Solway, was definitely English, and the English tongue was spoken in a large portion of the area.

Relations with England.—While this process of Anglicization was in progress, political relations with England were not, for many years, entirely friendly. The border-line between the two countries had not been definitely ascertained. As the rulers of Strathclyde, the Scottish kings imagined themselves to possess a claim to Cumberland and Westmorland, and they cherished an ambition of annexing portions of the old Northumbrian kingdom beyond the Tweed. The raids of Malcolm III. (Canmore) had led William I. to found Newcastle-on-Tyne in 1079 and William II. to fortify Carlisle in 1091, and the boundary line might be regarded as stretching from the Tyne to the Solway, although the English did not admit Scottish claims between Tweed and Tyne. The wife of David I. was the heiress of two English earldoms, of which Northumbria was one. Henry I. recognized his brother-in-law's claim to the earldom of Huntingdon, which descended to the Scottish queen from her father, but refused to acknowledge that Northumbria had passed to her from her grandfather (Earl Siward, who had played an important part in the reign of Edward the Confessor). When the English throne was disputed between Stephen and the Empress Matilda, David invaded England in support of the empress, who was his niece. His real purpose was to take possession of Northumberland, and he succeeded in effecting it in spite of his defeat at the Battle of the Standard, fought near Northallerton in Aug. 1138. Stephen, whose wife was also a niece of David, granted Northumberland as an English fief to Prince

Henry, the heir to the Scottish throne. The gift did not secure David's loyalty, for when the future Henry II. made his first, and unsuccessful, attempt to gain the English throne in 1149, David aided him and was promised the whole area north of the Tyne. This promise was repudiated by Henry II. on his accession in 1154. David had died in 1153, his son had predeceased him, and his grandson, Malcolm IV. (1153–65), had to surrender David's territorial gains.

Treaty of Falaise.—The ambition of annexing Northumbria continued to guide Scottish policy, and William the Lion (1165–1214), the brother and successor of Malcolm IV., hoped to attain it by joining the English rebels against Henry II. in 1173–74. His capture, near Alnwick Castle, in July 1174, not only put an end to such expectations but resulted in the temporary loss of Scottish independence. The 10th-century alliances against the Danes, in which the English king had been "father and lord" of the king of Scots, were by this time interpreted in England as having involved a feudal subjection of Scotland to England, and since the time of William the Conqueror, the Scottish kings had held English fiefs and had done homage for them. The precise nature of this homage had not been defined and the meaning of the ceremony was left deliberately ambiguous. What the Scottish kings gave as homage for English lands, English kings could receive as homage for the crown of Scotland. Henry released William only after forcing him to consent to the Treaty of Falaise (1174) by which he did homage avowedly for the Scottish crown. The treaty was cancelled 15 years later by an agreement between William and Richard I., who sold the rights extorted by his father, receiving in return a sum of money, required for the Third Crusade. The bargain (which forms almost the only link between Scotland and the Crusading movement) merely annulled the Treaty of Falaise and left the question of homage precisely where it had been in 1174. One ancient controversy was, however, settled immediately after the agreement was made. The Treaty of Falaise had expressly admitted the subordination of the Scottish to the English Church, but its provisions had not come into operation because it had failed to discriminate between the rival claims of Canterbury and York. In 1192, after the close of a controversy between William the Lion and the papacy, Pope Celestine III. issued a Bull declaring the Scottish Church to be the special daughter of the Holy See, "with mediation of none."[1] The church in Scotland was still denied the privilege of a metropolitan see, although in 1225 Honorius III. granted the clergy permission to hold regular provincial councils under the presidency of an elected "Conservator of the Privileges of the Scottish Church." It was not till 1472 that St. Andrews was given metropolitan jurisdiction in Scotland; 20 years later a province was detached and placed under the newly founded archbishopric of Glasgow.

The Golden Age.—William the Lion (the ascription of that title to him is an unsolved problem) continued to hope for the restoration of Northumberland. He offered to purchase it in 1194, but refused to accept it when Richard I. proposed to exclude from the bargain the right of holding fortified castles; and he made further unavailing efforts, including an admission of the right of King John to choose a wife for his son Alexander, the heir to the Scottish throne as well as to the possessions of the Scottish Royal House in England and to their Northumbrian claims—a dangerous expedient in view of English pretensions to overlordship. Alexander II. (1214–49) tried to seize Northumberland during the struggle which followed the grant of Magna Carta; but in 1236, by the Treaty of York, he resigned his claims to the earldom of Northumbria, and also his possessions in Huntingdon, in return for a grant of lands in the north of England. His reign witnessed the last of the Celtic revolts against the policy of Anglicization, and in his later years Scotland entered upon a period of consolidation and prosperity which continued throughout the reign of his son, Alexander III. (1249–86). The recovery of the Western Isles, which had been under Norse rule, was achieved by Alexander III. after the battle of Largs (1263), in which the Norwegians were defeated. In 1266 Eric of Norway surrendered the Hebrides in return for a money payment. There was continuous peace with England. Alexander was the nephew and also the son-in-law of Henry III., and his relations both with him and with his brother-in-law, Edward I., were friendly. The Borders, about to be the scene of almost incessant fighting for two and a half centuries, were quiet and peaceful. Later tradition did not err in regarding the reign of the last of the old line of Scottish kings as a golden age. His death closed the period of Anglicization and in the later middle ages Scotland drew its inspiration rather from France than from England.

[1]The date 1192 was established by Prof. R. K. Hannay in an article on the subject in the *Scottish Historical Review*, April 1926.

THE WAR OF INDEPENDENCE

The Succession Problem.—Alexander III. was killed by a fall from his horse in March 1286. His two sons and his daughter had predeceased him and his only living descendant was his daughter's infant child, Margaret, daughter of Eric of Norway. Her age, her sex and her nationality would have combined to prevent the succession of the little Maid of Norway, if there had been any adult male claimant nearly related to the late king. But Alexander left neither brother, nephew nor cousin, and there was no living legitimate descendant of any Scottish monarch later than David I. Of the three grandsons of David, two, Malcolm and William, had succeeded to the throne. The third, David, who had been given the English earldom of Huntingdon, had left a son and three daughters. The son had died without issue; the eldest daughter had married an Anglo-Scottish baron, and her grandson (through her daughter, Devorguilla, the foundress of Balliol college at Oxford) was, by the theory of primogeniture, the direct heir to the Crown. But the rule of succession by primogeniture was not yet established either in Scotland or in England, and the claim of John Balliol was disputed by Robert Bruce, the son of the second daughter of David of Huntingdon. Bruce argued that a grandson, being closer in descent to the grandfather from whom the claim was derived, was his true representative, rather than a great-grandson who was separated from him by an additional generation. Years before, when Alexander II. was childless, Bruce had been recognized as heir presumptive, and the birth of Alexander III. had deprived him of a chance which, in 1286, he held to have recurred. The Scots were thus faced by a choice between the minority of a baby girl who was the daughter of a foreign sovereign, and a civil war between two Scottish claimants. The nobles decided that the former was the lesser of the two evils, and the Great Council of Scottish tenants-in-chief, clerical and lay, appointed guardians to conduct the Government in the name of Margaret of Norway.

Agreement with England.—At first, it seemed as if the choice were to involve the country in both evils, for the Bruce party began to raise a rebellion, but Edward I. of England, a great-uncle of the baby queen, intervened to secure her throne. This intervention was welcome in Scotland; in the late king's minority, his father-in-law, Henry III., had taken part in Scottish politics, asserting no claim to overlordship, and describing himself as principal counsellor to the king of Scots. Edward I. similarly made no pretension to the right and duty of an overlord to act as guardian during a minority. The long continuance of peace with England, and the two centuries' tradition of the adoption of English speech, manners and institutions, made it natural for him to offer, and for the Scots to accept, a guarantee of the succession of the little Maid. Edward had, in fact, devised the statesmanlike scheme of a union of the two Crowns by the marriage of the heiress of Scotland to his son Edward (afterwards Edward II.). English, Scottish and Norwegian commissioners met to discuss the question, and in the summer of 1290, the Treaty of Birgham-on-Tweed defined the conditions of the marriage. In proposing his scheme, and in the terms of the treaty, Edward showed every consideration for Scottish feelings, and it was provided that, after the marriage, and even after the succession of a son of the marriage to both Crowns, the two kingdoms should remain separate organizations—doubtless Edward hoped that a union of the kingdoms would follow a union of the Crowns, but he was content to lay the foundations of that union. Further, it was agreed in the Treaty that, should there be no heir of the marriage, the Crown of

Scotland was to revert to the proper heirs, and the kingdom of Scotland was to be "free in itself, without subjection, as it hath hitherto been." Any rights pertaining to the Crown of England were reserved, but these rights were neither asserted nor defined.

The English Claim to Overlordship.—The agreement promised a peaceful future for both countries, as far as their relations with each other were concerned, but within two months, the Maid of Norway died on her way to Scotland (Sept. 1290). Civil war between the Bruces and the Balliols was inevitable, and each party wished to secure Edward's support. During the minority of Alexander III., the Bruce family had supported the policy of Henry III. in Scotland, and Robert Bruce, the claimant, was an English landowner, had held high official positions in England, and had fought with Edward during the Barons' Wars. There are indications that he would have acknowledged English overlordship in return for Edward's support, but such a bargain would not have fulfilled the purpose which Edward had begun to cherish—the reduction of Scotland to the position of a vassal kingdom of England. A compact with the Bruces would only have resulted in placing behind Balliol all who upheld Scottish claims to independence, and Edward was determined to obtain an acknowledgment of his paramount authority from all the claimants—there were rivals to Balliol and Bruce, but with clearly inferior pretensions. After collecting evidence from monastic chronicles about the history of the overlordship controversy, Edward asked the Scottish nobles to meet him at Norham-on-Tweed in May 1292. There he at once announced his intention of establishing his claim to be the feudal overlord of the kingdom of Scotland, and he gave the Scottish magnates some days to consider their attitude. Meanwhile, a great English army was assembling on the opposite bank of the Tweed. Edward's claim was not entirely repugnant to an assembly consisting largely of Anglo-Norman barons, some of whom held lands in England as well as in Scotland, and, after a protest had been entered in the name of the "community" of Scotland, the English overlordship was admitted and the admission was duly recorded. The Lord Paramount then ordered an enquiry into the pretensions of the various competitors, who were reminded that any symptoms of recalcitrance would be followed by a declaration that the kingdom, owing to failure of heirs, had reverted to the overlord. Edward then made a progress, as far north as Perth, through the kingdom of his (as yet unidentified) vassal.

Balliol's Revolt.—In Nov. 1292, Edward, after a judicial investigation, gave his decision in favour of John Balliol, thus defining right of succession in accordance with the later rules of primogeniture. Within three years the vassal king was in revolt against his overlord, who had subjected him to ignominious treatment. Whether Edward deliberately intended to produce this result is uncertain. Balliol's character and disposition suggested that he would submit to almost any humiliation rather than face Edward's wrath, and, if the English king did contemplate a conquest of Scotland, he cannot have wished to undertake it in 1295, when he had on his hands a Welsh rebellion, a French war and serious domestic quarrels. The remark attributed to him when news was brought of Balliol's alliance with France, "Has the fool done this folly?" indicates that he was surprised by the audacity of his vassal, and he was so far right that Balliol seems to have been compelled by Scottish opinion to take action. Edward at once assembled a powerful army to give effect to a new claim—that Scotland, as the fief of a disobedient vassal, had passed by forfeiture into the direct possession of the feudal superior. The strength of Scottish feeling is illustrated by the stubborn resistance offered by the Anglian population of the prosperous mercantile town of Berwick-on-Tweed, where English rule might have been expected to be more welcome than in any other province of Scotland. Edward took vengeance by a merciless massacre (the first act of warfare for nearly a century) and gave a precedent for a cruel and relentless struggle. At first, it seemed as if the conquest were to be a very simple process. Scotland was divided—the Bruces denied support to Balliol—and Edward, easily defeating a Scottish army at Dunbar (April 1296), made a triumphal march through Scotland. The annexation of the country, and its loss of the status even of a vassal kingdom, was emphasized by the destruction of the Great Seal, and by the removal to London of the national records and of the "Stone of Fate" upon which the Scottish kings were crowned. In October the English king returned home, leaving Scotland under a military occupation.

William Wallace.—English soldiers and officials were far from tactful, but the explanation of the revolt that followed is not to be found in garrison outrages. The lay magnates who had accepted the English overlordship were largely of Anglo-Norman blood; the smaller landowners and the lower classes of the population nourished a stronger dislike to English rule than did their natural leaders who had deserted the cause of independence. They found at once a new leader in Sir William Wallace, a younger son of a Renfrewshire landowner, and it was soon proved that only leadership was wanted to enlist an army of soldiers drawn from all parts of Scotland, including the Highlands. On Sept. 11, 1297, Wallace, as commander of "the army of the commons of Scotland," routed the English army of occupation at Stirling bridge, and for a year he ruled Scotland in the capacity of guardian for John Balliol. Meanwhile, Edward I., relieved both of foreign and of domestic anxieties, prepared to lead an army to Scotland in person. At Falkirk, on July 22, 1298, he defeated Wallace, who escaped but resigned his office of guardian. The victory did not, however, restore the English to the position they had held in 1296. The spirit of resistance, thoroughly awakened, was not dismayed by defeat. New guardians were appointed, including Robert Bruce, grandson of the Competitor (the future King Robert), and Edward, summoned to London by fresh domestic complications, had to leave Scotland unconquered. It was not till the autumn of 1303 that he was able to undertake operations on a scale adequate for his purpose. He brought a great army to Scotland in September, traversed the country, met with little resistance, and spent the winter in Scotland. In the summer of 1304, having captured Stirling Castle, which had been taken by the Scots after their defeat at Falkirk, he again left behind him what he believed to be a conquered country. In 1305 he captured Wallace and put the noblest of Scottish patriots to the cruel death prescribed by English law for a traitor.

Robert Bruce.—Wallace was executed in Aug. 1305. Six months later, Robert Bruce and John ("the Red") Comyn, both of them ex-guardians of Scotland, met secretly in the Greyfriars church at Dumfries. Comyn was a nephew of Balliol and was regarded as the representative of the Balliol claims. A meeting of the only two possible candidates for the Scottish throne must have been held for the purpose of adjusting their claims with a view to further resistance. The result of the conference was to make resistance inevitable and immediate. There was a quarrel, and Bruce stabbed Comyn; his followers despatched the wounded man. It was impossible for Bruce to conceal his real aims from Edward, and, though he had made no preparations for resistance, he was crowned in March 1306 at Scone. His chances of success seemed slight, for the kindred and friends of the great families of Balliol and Comyn were violently hostile to him; and the clergy, who had hitherto supported the cause of independence, were likely to be alienated by a crime which combined murder with sacrilege. A defeat at Methven, near Perth, in June, might well have put an end to the rising, and Bruce's failure in the battlefield was followed by other misfortunes. He spent the winter of 1306–07 as a fugitive—his adventures are described in Barbour's *Bruce* and in Sir Walter Scott's *Lord of the Isles* and *Tales of a Grandfather*. But Bruce was to prove himself a great national leader, the determination of the Scots to regain their independence had been strengthened by the death of Wallace, and even the clergy did not desert the new monarch in spite of a papal excommunication. In the spring, Bruce appeared on his own lands in Ayrshire, and in May he won a victory at Loudoun Hill in the same county. Then an event happened which changed the whole situation. Edward I. had spent the winter at Lanercost Abbey in the north of England, and had moved to Carlisle, where, in March, he sentenced to death two of Bruce's brothers who had fallen into his hands. On hearing the news of Loudoun Hill he resolved to lead

his army to Scotland in person, but he died at Burgh-on-Sands on July 7, and his successor abandoned the campaign.

Bannockburn.—Edward II. probably had adequate reasons for returning to London, but he missed a great opportunity in Scotland. One of his father's great difficulties had been that Scottish barons and bishops were ready to take, and just as ready to break, oaths of allegiance to the sovereign of England. He could not rely upon the unfailing support of any Scottish family or faction. The murder of Comyn had accomplished what all the first Edward's oaths had failed to achieve—the creation of an English party in Scotland which could be trusted unswervingly to maintain English interests. There was an irreconcilable blood-feud between King Robert and the friends and adherents of the murdered Comyn. Edward II. left this party without support and without any definite plan of campaign, and between 1307 and 1310 Bruce crushed its members individually. A futile and half-hearted invasion led by Edward in person in 1310 did nothing to retrieve the balance, and for the next four years, Bruce, with the help of his brother Edward, and of the "Black" Douglas, not only expelled English garrisons from Scottish castles but was able to inflict great damage by raids upon the northern counties of England. At last, in 1314, Edward II. made a serious effort to recover his father's conquest and suffered at Bannockburn (June 24) the greatest disaster which an English army had ever sustained. The fight was not of Bruce's seeking; he had avoided a general action in 1310 in accordance with the usual Scottish policy of guerrilla warfare. A pitched battle was too great a risk in view of the comparative resources of the two countries, and it was an imprudent challenge accepted by Edward Bruce from the English governor of Stirling Castle in the summer of 1313 that led to what proved to be the only successful battle on a great scale ever won by the Scots over the English. But Bannockburn was won, and it was sufficient for the vindication of Scottish independence. Edward II. stubbornly declined to admit the accomplished fact, and for many years Bruce carried terror into the northern counties, and he also dealt a serious blow to English dominion in Ireland. It was not till after the deposition and murder of Edward II. that the regents for his son, Edward III., agreed to the Treaty of Northampton (1328), by which England acknowledged the independence of the Kingdom of Scotland.

Revival of the Conflict.—In the following year, King Robert died, leaving as his heir a son, David II. (1329–71), who, though only a child of five, had already been married, in accordance with a provision of the Treaty of Northampton, to Joanna, a daughter of Edward II. In 1330, Edward III. threw off the yoke of his mother and her paramour, Mortimer, who had deposed his father, and a new phase of the War of Independence began. It was then that the most disastrous effects of the murder of Comyn began to operate. Bruce had vanquished the Scottish opponents whose bitter enmity that deed had provoked, but they had resolutely refused to acknowledge his sovereignty or, in the mediaeval phrase, to "come into his peace." Their estates had been forfeited and they had taken refuge in England. Thus, when England had again a strong king and Scotland a weak one, there was at the English court a body of "Disinherited Knights," as they were called, who urged the young Edward to wipe out the shame of Bannockburn, deeply felt by his people, and to reconquer Scotland. The Treaty of Northampton, confirmed by an English Parliament, stood in the way, but the conditions of the treaty had not been fully carried out by the Scots. It provided for the restoration of the estates of a few of the disinherited, and the Scottish regent, Randolph, earl of Moray, a nephew of King Robert, felt that it was not safe to take this step while the exiles were in favour at the English court. It was an ominous circumstance that the new English king had invited from France Edward Balliol, the heir of John Balliol, who was known to be contemplating an attempt to regain his father's vassal throne. In the summer of 1332, while England and Scotland were officially at peace, Edward III. permitted Balliol to lead an army of the disinherited for the recovery of Scotland. The earl of Mar, who had just succeeded to the regency on Randolph's death, was defeated by Balliol at Dupplin Moor (Aug. 12, 1332), and, in September, Balliol was crowned at Scone as Edward I. of Scotland. The English king then openly espoused Balliol's cause and, abandoning his grandfather's final policy of complete annexation, reverted to the earlier project of a vassal kingdom.

Before Edward III. could come to Balliol's assistance his vassal had been ignominiously driven out of Scotland, but he led a large army to the siege of Berwick-on-Tweed, which had been recovered by Bruce in 1318. The Scots suffered a crushing defeat at Halidon Hill, near Berwick (July 19, 1333), and the town fell into English hands. Edward then modified his consent to the revival of the vassal kingdom by extorting from Balliol a cession of most of the south of Scotland (including the counties of Linlithgow, Edinburgh, Haddington, Berwick, Selkirk, Peebles and Roxburgh). This district passed under the administration of English officials, but Balliol, in spite of successive invasions of Scotland by his overlord in the years 1334–37, never established himself as a vassal king. Then there occurred another change in the political situation, involving effects similar to those which had followed the death of Edward I., 30 years earlier. In the autumn of 1337, Edward III. put forward his claim to the throne of France, and he at once lost interest in Edward Balliol's feeble pretensions and even in the defence of the ceded territory. The Scottish regents were left, as Robert Bruce had been left, to suppress Scottish traitors and expel English garrisons, and by 1341, Perth, Stirling and Edinburgh were in Scottish hands, the English had been driven out of a large area in southern Scotland, and the young David II. was brought back from France, whither he and his English queen had been sent for safety in 1334.

Scotland and France.—The diversion of English ambition from Scotland to France really marks the close of the War of Independence, but it also inaugurated a new series of hostile relations between England and Scotland. Although John Balliol had made his original defiance of Edward I. in the assurance of support from Philip IV. of France, the help given by the French in the earlier stage of the struggle for independence had been negligible. In 1298, Philip agreed to a truce, and again in 1303, the darkest hour in Scottish history, he had concluded a permanent peace with England. When the struggle began again, however, the French, under Philip VI., had given refuge to the young David II., and French support of Scotland was one of the reasons for the English attack upon France. When that attack began in earnest, in 1346, Edward III. offered to restore the portions of Scotland which were still in English hands on condition of Scottish neutrality in the Anglo-French war. The Scots made a decision which, as time went on, they declined, on several occasions, to revoke. The explanation of their persistent adherence to a Franco-Scottish alliance lies in their conviction that no peace with England could possibly be permanent. If the English became the masters of France, they were not likely long to acquiesce in the existence of a small independent kingdom on their northern borders. If they failed to establish English dominion in France, they were equally sure to seek such compensation as a conquest of Scotland would afford, and the Scots, if they deserted France in her hour of need, could expect no help in their own. The Franco-Scottish alliance, as a factor in European history, began in 1346, when David II., invading the north of England in the interests of France, was defeated and captured at the battle of Neville's cross, fought near Durham on Oct. 17, about two months after Crecy. The English at once re-occupied a large area of southern Scotland and thus provided an unanswerable reason for the maintenance of Franco-Scottish friendship. While England held portions of France and of Scotland, an alliance of her two victims was inevitable. There was, indeed, no other bond of union between French and Scots, and the political alliance was by no means always a happy or cordial arrangement, although France took, in the development of Scottish civilization, the place which had been held by England before the War of Independence, and profoundly influenced Scottish law and institutions as well as manners and customs.

The Ransom of David II.—Scottish intervention in the Anglo-French war proved to be rather irritating than actually dangerous to England, and Edward III. made a remarkable attempt to get

rid of the complications which it involved. His prisoner, David II., was childless and extravagant; he hated his heir, Robert the Steward, the son of his half-sister and his own senior by some years. David was released in 1357 and the Scots undertook to pay a heavy ransom in instalments spread over many years. The Scottish Crown was thus impoverished, and David, who had been kindly treated in London and had made many friends in England, listened to a suggestion of the English king that the ransom should be commuted for an acknowledgment of an English prince as the heir to the throne of Scotland. The son of Robert Bruce actually made this proposal to the Scottish parliament, which contemptuously repudiated it. The long-continued negotiations for the ransom of David II. brought about an important change in the parliamentary constitution of Scotland. Whatever it may have derived from the Celtic heritage of the Kingdom, the Great Council of the land has been organized by the descendants of Malcolm Canmore upon an English model. It was both the supreme court of law and an advisory council of the sovereign, and it was composed of the tenants-in-chief, clerical and lay. To these two estates of the realm, the clergy and the barons, was added in the middle of the 14th century a third estate, consisting of representatives of the royal burghs. The financial help of the burghs was required for the payment of the ransom, and it was therefore necessary to secure their concurrence in the decisions taken by parliament. The presence of burgess representatives in parliament, or in the less formal meetings of the estates known as general councils, cannot be shown to have exercised any notable influence upon either the authority or the policy of the Crown, but it may be traced in a long series of legislative measures dealing with trade, commerce and police.

THE CONFLICT BETWEEN THE CROWN AND THE BARONS

The Early Stuart Kings.—The War of Independence, and the subsequent warfare with England, deeply affected the relations between the Crown and the great baronial families. The distribution of the estates of the "disinherited" among Bruce's supporters was one of the causes of the dangerous greatness of the House of Douglas and of other Scottish families, and, in the course of the English wars, the Crown was frequently weakened by the premature deaths of monarchs and by the recurrence of minorities. The initial weakness of the Crown, after the death of Robert I., was, however, due not to such accidents, but to the personality of his first three successors. David II. was a futile ruler and a worthless man, and the determination of the Scots to maintain their independence receives additional proof from the circumstance that his reign did not witness its loss. When he died in 1371, the nephew who succeeded him, Robert II. (1371–90), the first monarch of the House of Stuart, was 55 years of age, and already worn out by a strenuous public life. His reign was largely spent in conflict with England, but he took no part in the warfare. Scotland had been included in truces between England and France, and when the Anglo-French struggle entered on a new phase in 1377, the Scots renewed their efforts to expel the English from the occupied country in the south, and their success provoked invasions by John of Gaunt and by Richard II., which resulted solely in devastations of Scottish soil. The best remembered incident was the battle of Otterburn (1388), a chivalrous and romantic episode, but negligible as a military event. The next king, Robert III. (1390–1406), was a lame old man who with some reason described himself as "the worst of kings and the most wretched of men." His legitimacy was doubtful, and he made no effort to repress the disorders which were rampant in the country. During the early years of his reign the Government was in the hands of his younger brother, the earl of Fife, whom he created duke of Albany, but in 1399 his eldest son, the duke of Rothesay, ousted his uncle from the regency. There was a bitter feud between Rothesay and Albany, the latter of whom recovered power in 1401. In the following year Rothesay died mysteriously at Falkland (the story is told in Scott's *Fair Maid of Perth*), and rumour, which has crystallized into tradition, ascribed his death to Albany. The old king was alarmed by the fate of his heir, and, early in 1406, he sent his remaining son, Prince James, to be educated in France. The boy was captured by the English at sea, and Robert III. died when the news reached him. The reign of James I. nominally covers the years 1406–37, but he was a prisoner in England till 1424, and during this period Scotland was governed by Albany until his death in 1420 and thereafter by his son, Murdoch, 2nd duke. The regency of the elder Albany witnessed the foundation of the first Scottish university (St. Andrews, 1411)—partly an endeavour to repress the Lollard heresy which had reached Scotland—and the battle of Harlaw, which has frequently been misinterpreted as a decisive struggle between Celt and Saxon in Scotland. It was, in fact, a fiercely fought skirmish between Donald of the Isles, a grandson of Robert II., who claimed the earldom of Ross in right of his wife, a member of a Lowland family, and the burghers of Aberdeen, reinforced by the earl of Mar and other Aberdeenshire lairds. Donald, having defeated the Mackays and the Frasers, Highlanders who opposed his claim, was marching to plunder the town of Aberdeen. Like other disaffected Scottish barons, he had made an alliance with England, and Harlaw was an episode in Anglo-Scottish warfare. Albany made considerable progress in the recovery of southern Scotland from the English, and he also encouraged the recruitment of Scottish soldiers for the struggle in France. In the year after his death the Scots rendered their most distinguished service to the French in helping to win the victory of Baugé (1421), the first French success since the invasion of France by Henry V. of England.

The first two Stuart kings had been feeble rulers, and though the elder Albany was a strong man, his position, and possibly his personal ambitions, prevented him from suppressing the feudal anarchy which threatened the monarchy and paralyzed the central administration. James I., who was released on payment of a ransom in 1424, was fearless and determined, and he resolved to establish order and good government—in his own words, to "make the key keep the castle and the bracken bush the cow." He was merciless in his treatment of the great barons, and he roused many enemies. He tried to find support for his reforms in widening the membership of the Great Council or Parliament by establishing a representative system for the lesser barons whose technical obligation to attend its meetings had never been enforced, but the statute passed in 1428 for this purpose was inoperative. None the less, the parliaments of the reign passed a long series of beneficent legislative measures; the king's difficulty lay in enforcing them. In 1437 he fell a victim to a conspiracy organized by the earl of Athol, a relative who, if the legitimacy of Robert III. had not been recognized, would have been the rightful occupant of the throne. His son and successor James II. (1437–60) was a child of six, and the advance made by the central government during the personal rule of James I. was lost in the intrigues and factions of a minority. When James II. began his personal rule, the great House of Douglas, in spite of sustaining a severe blow by the murder of its young chief in the course of the royal minority, was a grave danger to the supremacy of the Crown. James found a pretext for invading the Douglas dominions while the 8th earl of Douglas was on a pilgrimage to Rome, and Douglas, on his return, made a league with his three brothers, Archibald, earl of Moray, Hugh, earl of Ormond, and John, lord of Balveny, and with a great northern magnate, the earl of Crawford. The king heard of the league and sent for Douglas to Stirling Castle, giving him a safe-conduct. The earl refused to break the bond into which he had entered, and James, losing his temper, stabbed him and wounded him fatally (Feb. 1452). An obedient parliament found that the Earl was "guilty of his own death by resisting the king's gentle persuasions to aid him against rebellious subjects," but the murder was necessarily the signal for a final conflict between the Crown and the House of Douglas. James defeated the Douglases on the battlefield and captured their strongholds, and the 9th earl fled to England to reappear in Scotland in the next reign.

Recovery of Southern Scotland.—The Douglases had been involved in many intrigues with England, but they had played a notable part in the recovery of southern Scotland, and by the year 1460 this task had been completed except for the town of Berwick-on-Tweed and the castle of Roxburgh; the town of

Roxburgh, once one of the leading Scottish burghs, had been entirely destroyed in the course of more than 160 years of almost continuous warfare. The outbreak of the Wars of the Roses in England afforded a suitable opportunity for the recovery of the castle, and James besieged it in the summer of 1460. He himself, interested in the growing use of artillery, was watching the operations of his gunners, when he was hit and killed by "a piece of mis-framed gun that brak in the shooting," and Scotland was again plunged into the woes of a minority. Roxburgh Castle was taken a few days after the king's death, and with the expulsion of the English from Scotland, the real reason for the Franco-Scottish alliance had come to an end. While the English held large portions of France and of Scotland alike, an alliance of their two enemies was inevitable, and James I. had repeated the Scottish refusal of English offers of friendship on condition of Scottish neutrality in the French war. The Scots had rendered greater military assistance to the French than they had received from them, but it was the French who bore the brunt of the conflict against the common enemy, and, in negotiations with the English, they never failed to protect Scottish interests. By 1460 the alliance had served the purpose for which it was formed; the English held only Calais in France and Berwick in Scotland.

The Reign of James III.—During the minority of James III. (1460–88), the Scots took advantage of the civil war in England to obtain the cession of Berwick-on-Tweed from Margaret of Anjou, the wife of Henry VI., giving in return some help to the Lancastrian cause. Edward IV. retaliated by an intrigue with the Lord of the Isles, but the Scots recognized the accomplished fact of Yorkist supremacy in England and a truce was made in 1463 and converted into a peace in 1464. During the first years of the minority of James III., Scotland was ruled by a statesman, Bishop Kennedy of St. Andrews, and though there were troubles after his death, the young king, when he assumed the government in 1469, began his reign in fortunate conditions. There was peace with England; his father had destroyed the perilous greatness of the Douglases; his marriage with Anne of Denmark led to the recovery of the Orkney and Shetland islands, which had been Scandinavian for centuries; and the prestige of the kingdom was enhanced by the creation of the metropolitan see of St. Andrews in 1472. Four years later the Lord of the Isles was reduced to submission by an army led by some of the great barons whose ambitions had hitherto been dangerous to the Crown. Yet James III. was one of the most unfortunate of the Stuart kings. His nobles complained that he "delighted mair in music and policy of building than in the government of his realm," and they preferred his brother, the duke of Albany. The brothers quarrelled, Albany fled to France, and James was sufficiently unwise to break the peace with England, where the 9th earl of Douglas was still in receipt of an English pension. With Douglas as an intermediary, Edward IV. made a treaty with Albany for his establishment on the Scottish throne as an English vassal, and for the restoration of the House of Douglas. Albany, calling himself Alexander, king of Scots, led an army to the Borders, accompanied by Richard, duke of Gloucester (afterwards Richard III.). Gloucester retook the town and castle of Berwick-on-Tweed, which thus passed finally out of Scottish hands (1482), and Albany invaded Scotland. The army which James led to meet him brought about a revolution; the nobles, under the leadership of the earl of Angus, the head of the Red Douglases who had risen on the ruins of the older or Black Douglases, seized and hanged the musicians and architects who were the king's friends, and made an agreement with Albany. The amusing story of how Angus gained his nick-name, Archibald-Bell-the Cat, is told in Scott's *Tales of a Grandfather*. In the following year, Albany was again an exile in England, and in 1484 he and Douglas again invaded Scotland with a small English force, but were defeated. Albany escaped to France, where he was killed in a tournament in 1485, and the 9th and last earl of Douglas died a prisoner in the monastery of Lindores.

Four years later James III. was killed in a civil conflict. The faction of the nobility which conspired against him and defeated him at Sauchieburn, near Stirling (June 1488), had seized the person of his son and heir, the prince of Scotland, and brought him to the field against his father. This circumstance indicates the permanent character of the change in Scottish politics brought about by the victory of James II. over the Douglases. Neither of the two rebellions against James III. was directed against the dynasty, and each of them was the result of widespread political opposition to the king's conduct of public affairs, and not of secret conspiracies inspired by jealousy of the House of Stuart. It is also significant that, in 1488, the rebels made a defence of their action on political grounds; rebellion, for the first time, admittedly required an excuse capable of being stated openly. The revolution was followed by indications of a tendency towards constitutional government and an assertion of parliamentary authority, but this tendency did not survive the assumption of power by James IV. (1488–1513) in person. He was an able and strenuous ruler, and he soon acquired complete control over the traditionally amenable Scottish parliament. He humbled rebellious barons, who, either as partisans of the late king, or for other reasons, resisted him, and he annexed to the Crown the title of Lord of the Isles and by personal visits established royal authority in the Hebrides.

SCOTLAND, ENGLAND AND FRANCE

Union of the Thistle and the Rose.—James IV. aimed at acquiring for Scotland a place in European politics. The causes which, for nearly two centuries, had compelled his kingdom to follow the policy of France had ceased to operate, he was himself related to the rulers of Denmark and Burgundy, and he was ambitious of a marriage alliance with Spain, then under Ferdinand and Isabella. He built a Scottish navy and challenged England on the seas. In alliance with the Emperor Maximilian and the duchess of Burgundy, he supported Perkin Warbeck's pretensions to the throne of Henry VII., and made a half-hearted invasion on his behalf. The Spanish sovereigns were in frequent communication with James and sent to Scotland an envoy who has left an interesting account of the social condition of the country in the last years of the 15th century. Failing to obtain a Spanish bride, he accepted Henry VII.'s offer of the hand of his elder daughter, Margaret, whom he married in 1503. The marriage, celebrated by the poet Dunbar as the Union of the Thistle and the Rose, implied a fresh orientation of Scottish policy and dealt a blow to the tradition that Scotland must always be on hostile terms with its great neighbour, and a period of some 15 years of peace brought a great increase of commercial prosperity to Scotland. But James, on more than one occasion, indicated to Henry VII. that he had no intention of being ruled by his father-in-law, and he continued to build a great navy. Peace was maintained while Henry VII. lived, but the accession of Henry VIII. soon placed before James the old alternative of friendship with England or with France.

Flodden Field.—The formation of the Holy League against France alarmed the Scottish king, who dreaded the effect upon Scotland of the destruction of France by a great European combination. That France was in no such danger as he imagined is proved by the circumstance that, a year later, Henry VIII. married his sister to Louis XII., but it is easy to understand James's alarm. He was willing to yield to his brother-in-law on other points of dispute which had arisen between the two sovereigns, but he resolved to maintain the traditional Scottish policy of helping France in her hour of need. It is, however, significant that the royal decision was persistently opposed by the older and wiser councillors, who, though themselves trained in the French tradition and bound to France by many personal ties, realized that circumstances had changed, and that what had been wisdom less than a century earlier was likely to be folly in the new conditions. This view found expression, a few years later, in the *History of Greater Britain*, by a famous Franco-Scottish scholar, John Major, who urged the expediency of a union of Scotland with England. James took his own way and in Sept. 1513 he was defeated and killed in the battle of Flodden. His heir was an infant, and Scotland, overwhelmed by a great national disaster, was again subjected to the intrigues of a minority. The navy,

upon which James IV. had lavished care and money, was sold to France, and the country did not recover, for at least a century, the prosperity which had marked his reign.

The Regency of the Duke of Albany.—James, by will, had left his English wife as the guardian of his infant son, James V. (1513–42), and she might have secured the regency if she had not married a Scottish nobleman, the earl of Angus, in 1514. Her second marriage rendered her position impossible and the Scots invited Alexander, duke of Albany, the son of the traitor duke of the reign of James III., to become regent. Albany, who had been born and educated in France, spoke no language but French and he spent a considerable portion of his regency (1515–24) in Paris. If Margaret and Angus had set themselves resolutely to champion English influence in Scotland, they could have smoothed the way of English diplomacy. But Margaret, a true sister of Henry VIII., quarrelled with her second husband and tried to obtain an annulment of her marriage, disregarding Henry's remonstrance that she had chosen her husband and, by the laws of God and man, was bound to stick to him. Angus maintained the Douglas tradition of intrigue with England, but Margaret, dominated by hatred of her husband, frequently acted in the interests of France and checkmated English designs in Scotland. In July 1524, Margaret, in conjunction with the earl of Arran, heir-presumptive to the throne, declared the young king to be old enough to rule in person, but Arran deserted her and made friends with Angus, who governed the kingdom until 1528, when James, who hated his stepfather, made a romantic escape from his control.

James V. and Henry VIII.—Under the influence of his mother, who had been freed from Angus by a decision of the Papal Court in 1527 and had therefore no reason for hostility to Henry VIII., James, for a few years, was on friendly terms with his uncle. After the English breach with Rome, when Henry felt his isolation in Christendom, he urged his nephew to follow his example and enrich himself with the spoils of the monasteries. The Reformation was, by this time, making some progress in Scotland, but James, though he recognized the need of a reformation of the lives of the clergy, had no sympathy with the new doctrines, and he was not prepared to adopt Henry's methods. He made two French marriages; after his first wife, a daughter of Francis I., died, as a bride, in 1537, he married Mary of Guise, widow of the duc de Longueville. Henry, however, persevered in trying to detach James from his French alliance and to alienate him from Cardinal Beaton, the leader of the Church Party; he continued to urge him to dissolve the monasteries, and made various attempts to arrange a personal interview; we now know that he intended to kidnap him. James declined his uncle's overtures and refused to give him a chance of seizing his person, and Henry broke off friendly relations, revived the claim of homage, and sent armies to invade Scotland.

James was not supported by his nobility. His conflict with Angus had embittered his relations with the great families at the beginning of his reign; he offended the Border chiefs by restoring order in the Borders, and in carrying out his father's policy in the Western Isles, he quarrelled with the earl of Argyll. The result was that he had come more and more to rely upon the support of the clergy, and by this and by the employment of favourites he still further alienated the nobles. The opposition of the Scottish nobility to James V. was stimulated by the Tudor methods of bribery, and their eyes were fixed on the spoils of the church. They refused to support James in what they called a French war, and it was Beaton and the ecclesiastical party that furnished James with the army that was routed at the battle of Solway Moss in Nov. 1542. The king's health had prevented his taking part in the fighting, and he returned to Falkland Palace, where he died on Dec. 14, six days after the birth, at Linlithgow, of his daughter and heiress, Mary Queen of Scots.

The Minority of Queen Mary.—The death of his nephew gave Henry VIII. a great opportunity which he failed to use, for the new rulers of Scotland might have been persuaded to accept the Reformation and seize the lands of the Church. The regent, the earl of Arran (a son of the Arran of the preceding reign, and, like his father, heir-presumptive to the throne) was appointed in defiance of the efforts of Beaton and was known to incline to the new doctrines. Henry succeeded in negotiating, in July 1543, the preliminaries of a marriage treaty between his heir (afterwards Edward VI.) and the infant Queen of Scots, but he followed up this success by making demands which the Scots indignantly refused, and he was known to have plotted to kidnap the regent and the queen-mother, Mary of Guise. The result was a reconciliation between Arran and Beaton and the repudiation of the English marriage treaty (Dec. 1543). If Henry had been patient he might have won in the end, for Arran and Beaton were likely to quarrel, and the temptation to dissolve the monasteries during a minority of the Crown would have been very strong. But Henry lost his temper, and his brother-in-law, the earl of Hertford (afterwards Protector Somerset), ravaged southern Scotland in 1544 and 1545—his merciless campaigns were derisively known as "the English Wooing." Scotland was thus thrown once more into the arms of France, and the murder of Beaton, the leader of the French party, in his own episcopal castle of St. Andrews (1546) did not affect the political situation. His murderers were glad to have English help in defending the castle of St. Andrews, but a national alliance with England was impossible for the time.

Protector Somerset carried on the policy of Henry VIII. His personal attitude to the Scottish problem was wiser than that of his late master; he aimed at a union on equal terms, and, if he had come into power in 1542 instead of in 1547, the course of events might have been widely different. As it was, all that he could do was to employ force in an endeavour to sever the Franco-Scottish alliance, and in this he completely failed, though he gained some military reputation by his third invasion of Scotland and his victory at Pinkie in Sept. 1547—the last of the old battles between England and Scotland. Meanwhile, the Scottish Government had, with French help, captured the castle of St. Andrews (July 1547), and the Regent Arran entered into negotiations for a marriage of the girl queen to the heir of the French throne. In Aug. 1548 Mary was sent to France, where she remained for 13 years. The French continued to assist the Scots to recapture strongholds taken by the English, and the Auld Alliance seemed to be more firmly cemented than ever when peace was made with England in 1551.

End of the French Alliance.—But France had become too great a Power to treat Scotland on equal terms, and Henry II. was determined to make the country a province of France. Arran was bribed to resign the regency in favour of Mary of Guise, and the new regent, as her recently published correspondence shows, became an agent of French policy. She was surrounded by French advisers—a Frenchman shared with the earl of Huntly the dignity of the chancellorship—and she relied upon the services of French soldiers, who had always been unpopular in Scotland. The Scots were alarmed. They spoke of Scotland as threatened with the fate of Brittany, and parliament in 1555 had to pass an act against slanderers of the queen regent and of the French troops "sent for the common weal and suppressing the auld enemy." There were several outbreaks against the French garrisons. Anti-French feeling was stimulated by the growth of the Reformed doctrines, which had been spread by the "cartloads of Bibles" that Somerset is recorded to have brought with him. In 1557, the Scottish Protestants formed a league which they called "the Congregation of the Lord," and signed the first National Covenant in the interests of Protestantism.

The marriage of Queen Mary to the Dauphin in April 1558 was celebrated with due rejoicings in Scotland, but it rather injured than assisted the French cause, for there was a suspicion, which is now known to have been well-founded, that agreements signed by the girl-queen on her marriage formed a danger to the independence of the country. Mary had, in fact, been induced to sign documents which, in the event of her decease without issue, transferred the succession to the French king and his heirs, a stipulation which directly contravened assurances solemnly given by Henry II. to the Scottish parliament.

The Lords of the Congregation.—The revolt of the Scot-

tish Protestants against the French alliance and the Roman Church was hastened by events in England. While Mary Tudor lived, they could form no English alliance, in spite of the English queen's hostility to France. When Elizabeth succeeded in Nov. 1558, Henry II. was guilty of the foolish insult of asserting the claim of his daughter-in-law to the English throne as the nearest heir of Henry VII.—Elizabeth being, in the eyes of Roman Catholic Europe, an illegitimate child. It was, therefore, in the interests of England to help the Scottish Protestants against the Scottish Government, and it happened that the queen regent chose this unfortunate moment for severe measures. In 1559 she denounced the Protestant leaders as heretics, and their reply came in the form of the destruction of the religious houses at Perth. Alarmed by the outbreak, Mary of Guise promised not to send a French garrison to the city, but her arrival at Perth with a personal bodyguard of French soldiers was interpreted as a breach of her promise. The destruction of religious buildings continued, and the Protestant leaders, known as the Lords of the Congregation, invited English help. Henry II. was killed in the summer of 1559, and the king of France, Francis II., became, in right of his wife, king of Scots. The Guises were the Government of both France and Scotland, and France, just released from the burden of a Spanish war, was free to prosecute its policy in Scotland. But the Lords of the Congregation gave the Scottish Government no time for preparation. In Oct. 1559 they announced the deposition of the queen regent, and asked Elizabeth "to accept the realm of Scotland into her protection and maintenance, only for preservation of them in their old freedom and liberties, and from conquest, during the time the marriage shall continue between the Queen of Scots and the French King."

QUEEN MARY IN SCOTLAND

The alliance between Elizabeth and the Protestants marks the end of the Franco-Scottish League and the triumph of the Reformation in Scotland. An English fleet besieged Leith, and the queen regent, stricken with mortal illness, took refuge in the castle of Edinburgh, where she died in June 1560. There was no one to represent the authority of the Crown, and a Scottish parliament, the legality of the summons of which was doubtful, abolished Roman Catholicism and prohibited under severe penalties (culminating in capital punishment) the celebration of Mass. The parliament of 1560 secured the *de facto* establishment of Protestantism, though its legislation was not ratified by the Crown. Mary's husband died in Dec. 1560, and she returned to Scotland in Aug. 1561. At first she was guided by her half-brother, whom she made earl of Murray. Any attempt to restore her own religion was out of the question. The utmost that Mary could seriously hope for was a toleration for Roman Catholics, and her efforts to secure this were unsuccessful. She could not even protect the worship of her own attendants in her own chapel, and John Knox afterwards said that on her first arrival, he could have "executed God's judgments upon her" if he had chosen to do so. England and Protestantism were definitely in the ascendant, and the new Church became stronger than ever when, in 1562, Murray secured Mary's acquiescence in the suppression of the earl of Huntly, the most powerful Roman Catholic nobleman in Scotland.

Darnley and Rizzio.—A marriage with a foreign prince might have strengthened Mary in Scotland, but she was restrained from this course by her position as heiress-presumptive to the English Crown. Nine years younger than Elizabeth, Mary judged that she would outlive her, and the main aim of her policy was to secure a recognition of her claim to the succession in the event of Elizabeth dying without issue. Elizabeth threatened that if Mary made a marriage with a foreign prince, steps would be taken to debar her succession to the English Crown, and, for some years, she amused herself with insincere suggestions for the Scottish queen's marriage. In July 1565, Mary married her cousin, Henry, Lord Darnley, who, as the representative of their grandmother, Margaret Tudor, by her second marriage (with the earl of Angus), stood next to Mary herself in the succession to the English throne. He was also next to the Hamiltons in the succession to the Scottish throne. Elizabeth had allowed Darnley (who had been brought up in England) to go to Scotland, and the marriage was in no way antagonistic to English interests; but she declared herself offended and secretly sent aid to Murray, who raised a rebellion against the marriage. Her people supported Mary, and Murray fled to England. Darnley proved an impossible husband, and his foolish ambition sought a somewhat mysterious right known as the Crown Matrimonial, which would have secured the throne to him for life and might even have given his children by a second wife precedence over the Hamiltons in the succession to the throne. He had made many enemies, and no friends, in Scotland, and Mary's Italian secretary, David Rizzio, was known to have advised Mary to refuse her husband's request. Darnley became involved in a plot for the murder of Rizzio. The murder was only a small part of the design of the conspirators, who included Murray and the other exiles in England and their friends in Scotland. Darnley was led to believe that his accomplices would give him the authority of a king regnant. Rizzio was murdered on the evening of March 9, 1566, and, the same night, Murray arrived from England, where Elizabeth had been cognizant of the plot. Then Mary, in an interview with her husband, persuaded him that he was the dupe of his accomplices, and, on the night of March 11, husband and wife escaped from Holyrood, and fled to Dunbar. Public opinion again supported Mary, and, while Murray remained in Scotland, the nobles who had taken part in the Rizzio murder had to flee to England. Darnley disavowed any knowledge of the plot, and bitterly opposed any suggestion of pardon for his fellow-conspirators, who supplied Mary with full evidence of his guilt.

Mary's two successes alarmed the Protestants, and if Mary could have retained her hold over Darnley, the Reformed Church might have been in some danger. But the birth of a son, Prince James, in June 1566, was followed by a violent and permanent quarrel between the unhappy parents. Darnley's enemies were resolved to have his life, and when the accomplices whom he had betrayed were allowed to return to Scotland at the end of 1566, he was a doomed man. But the enemies of Darnley were also the enemies of Mary, and they found in the earl of Bothwell, a tool for the destruction of both. Darnley was murdered on Feb. 10, 1567, at Kirk-of-Field, in the outskirts of Edinburgh, and his murderers, by blowing up the house with gunpowder, made sure that no alternative explanation of his death should be feasible. Bothwell was known to be a principal actor in the crime, and a collusive trial did nothing to weaken the belief in his guilt. On May 15 Mary married Bothwell. There was another rebellion, the queen had been discredited by the Darnley murder and the Bothwell marriage, and she had no option but to surrender to the rebels (June 15). The question of Mary's guilt or innocence of her husband's murder is rather biographical than historical (*see* CASKET LETTERS). Guilty or innocent, she could not retain her authority after what had happened. If, as in the present state of the controversy unfortunately seems probable, there was a domestic conspiracy between Mary and Bothwell, Darnley's death was not merely the result of a plot between a guilty wife and her paramour. If Mary was an accomplice of Bothwell, she was also the unconscious tool of a wider conspiracy, the members of which, after she and Bothwell were both out of the way, fell to accusing each other of a share in the murder of Darnley.

Mary's Abdication.—The insurgent lords imprisoned Mary in Lochleven Castle and forced her to abdicate in favour of her infant son, and Murray extorted from her an assent to his own appointment as regent. Within a year, she escaped from Lochleven, and a few days later her army was defeated at Langside. Relying on an invitation sent by Elizabeth to her in Lochleven, Mary took refuge in England, where she was imprisoned by the English Queen (May 1568). Her vigorous and attractive personality had introduced a new element into Scottish politics, for, in her army at Langside were Protestants whose interest in the struggle was loyalty to the queen, and during the first years of her English imprisonment, her party in Scotland, which gave considerable trouble to successive regents, was, for a variety of reasons, maintained by two Protestants, Maitland of Lethington

and Kirkcaldy of Grange. Her fall meant the complete triumph of English influence, for Elizabeth had only to threaten to release her prisoner in order to exert pressure on the regents. The Regent Murray (1567–70), the Regent Lennox (1570–1), the Regent Mar (1671–2) and the Regent Morton (1572–8) were all on friendly terms with Elizabeth, and they had English help in the civil war between the king's party and the queen's party. The troubled state of the country, until the capture of Edinburgh Castle in 1573 put an end to the resistance of Mary's adherents, is illustrated by the fate of the first two regents. Murray was assassinated and Lennox died of wounds received in a skirmish at Stirling.

THE STRUGGLE BETWEEN THE CHURCH AND THE CROWN

Andrew Melville.—Mary's fall also meant the complete triumph of Protestantism, and the Protestant Church was legally established by parliament in 1567. Its early organization was the work of John Knox, and the presbyterian system which became its characteristic feature was introduced by Andrew Melville, under whose guidance the General Assembly (*see* SCOTLAND, CHURCH OF) insisted upon the essential parity or equality of all ministers and abolished a modified form of episcopal government which had originated in Knox's institution of superintendents charged with the oversight of districts corresponding to the old dioceses. The superintendents, who had come to be known as bishops, were purely administrative officers and did not claim to possess orders superior to those of the ordinary clergy. Their administrative powers were conferred in 1580–81 upon the courts of the Church known as Presbyteries. Under Melville, the Church developed a claim which had been less rigidly advanced by Knox—that the ecclesiastical authority, the Power of the Keys, is different from, and independent of, the civil power. This theory was bound to produce a conflict between Church and State, and it was maintained so thoroughly that the ministers claimed to be responsible for their pulpit utterances to the Church courts and to them alone, and this at a time when ecclesiastical considerations affected every question both of domestic and foreign policy. The claims of the Church caused friction with the earl of Morton, and, after his fall, the young James VI. (1567–1625) waged an incessant struggle against them, and, even before his accession to the English throne, had established a royal control over the Church.

James VI., Mary and Elizabeth.—Morton was compelled to resign the regency in 1578. He made a temporary recovery of influence, but in June 1581 he was executed for his share in the Darnley murder, and James, at the age of 15, became responsible for the Government. He roused opposition by relying upon a Roman Catholic favourite, Esmé Stuart, a cousin of Darnley, whom he made duke of Lennox. The favourite professed a conversion to Protestantism and James tried to suppress any alarm by initiating a new National Covenant (1581) which denounced "the usurped authority of that Roman Anti-Christ," but the extreme Protestants kidnapped James in the raid of Ruthven (1582), and Lennox had to flee. In 1583 James escaped from his captors and fell under the influence of a new favourite, whom he created earl of Arran. A rebellion was nipped in the bud, and the earl of Gowrie, one of the leaders of the raid of Ruthven, was executed. During this time James was in friendly negotiations with his mother, and he intrigued with the duke of Guise, and even with the pope. Elizabeth, on her part, was encouraging the opposition to James, as she had encouraged the opposition to his mother and grandmother. But James was alarmed by the rise of the Catholic League in France, his success in dealing with Gowrie made him less desirous of possible aid from Roman Catholic powers, and Arran persuaded him that his best chance of the English succession, on which his heart was set, lay in friendly relations with Elizabeth. Arran fell a victim to his own advice, for Elizabeth distrusted him, and when James came to terms with her, he dismissed him. In the end of 1585, James made an offensive and defensive league with England, and when, a year later, Mary's life was in danger, he refused to risk his chance of the succession by threatening to break the league if Elizabeth should put his mother to death. The approaching Spanish invasion made the friendship of Scotland more important to England than it had ever been before, but James made no real effort on Mary's behalf and apologized for such efforts as he did make. The execution (Feb. 1587) caused intense indignation in Scotland, but James succeeded in keeping the country quiet, and in the following year he took steps to resist the Armada.

James and Spain.—While James would not imperil his English claims for the sake of his mother's life, his impatience with Elizabeth's longevity led him to take grave risks by intrigues with the enemies of England. In 1589 he aroused suspicion by his lenient treatment of two Roman Catholic earls, Huntly and Errol, whom Elizabeth's ministers had detected in correspondence with Spain, and in 1592, the English Government came into possession of the "Spanish Blanks," a series of papers bearing only the signatures of Huntly, Errol and Angus. Letters from these earls which accompanied the blank forms showed that the "Blanks" were intended to contain a treaty with Spain for the invasion of England, and it was proved that James was aware of the project. His views on what could be said for and against it are preserved in a document in the *Hatfield Papers*, vol. iv., p. 214. It was only because Cecil regarded James as the least of the possible evils from among which England would have to choose on Elizabeth's death, that action was not taken to incapacitate him from succeeding her. Elizabeth meanwhile retorted by intrigues with James's Protestant opponents in Scotland, and it was not till the last year of her life that the relations between the two sovereigns were really friendly.

James and the Church.—Meanwhile, James had been pursuing his quarrel with the Church. After the execution of Gowrie in 1584, he took vengeance on the earl's Presbyterian supporters by persuading parliament to pass the "Black Acts," which asserted a royal headship over the church and empowered the sovereign to appoint bishops and to decide when assemblies should meet. He tried to meet the challenge to the civil power which was involved in the authority claimed and exercised by the assembly, by means of an increase in the prestige of parliament, and in 1587 an act was passed instituting a representative system for the smaller barons in the counties. But the parliament was, at the same time, brought so completely under royal control that it never rivalled the influence of the assembly. The Spanish intrigues of the Catholic earls strengthened the Presbyterian Party and James in 1592 had to permit parliament to pass the "Golden Act" which gave a legal status to the church courts and repealed the legislation of 1584 in so far as it interfered with the freedom of the Church. Two years later he was compelled to suppress the Catholic earls, but a quarrel with the Church in the end of 1596, in which the ministers adopted an untenable position, gave him what proved to be a permanent victory. He acquired a large measure of control over the general assembly, and he obtained its sanction for the appointment of titular bishops, to whom he gave seats in parliament.

Plots and Conspiracies.—Up to the year 1603 James conducted his administration of Scotland under serious difficulties. The revenues of the Crown were insufficient to meet the expenses of Government, and, though, in 1596, a commission of eight leading Scottish statesmen, known as the Octavians, brought the royal finances into something like order, the king's political action and his personal expenditure were under the restraint of an impoverished exchequer. In 1587 pecuniary necessities led him to pass an act annexing ecclesiastical property to the Crown, an expedient which he soon found to be inconsistent with his ambition of restoring episcopacy in the Church. Like his predecessors, he had to be on guard against conspiracies. The raid of Ruthven was the only successful plot in the reign, but the outrages of Francis, earl of Bothwell (a nephew of Queen Mary's third husband), caused James some alarm, and, as late as 1600, the Gowrie conspiracy, if the king's very doubtful statements about it can be credited, was an attempt by the sons of the 1st earl of Gowrie to repeat the raid of Ruthven. It is to James's credit that he succeeded in introducing something like order into the Borders and the Highlands, even if the methods which he employed to attain

this end were cruel and unscrupulous.

The Union of the Crowns.—The accession of James to the English throne in March 1603 entirely altered his position in Scotland. Intrigues with the sovereign of England were no longer possible either for rebellious Scottish barons or for discontented Scottish preachers. The absence of English support rendered rebellion a dangerous expedient, popular opinion, absorbed in religious controversy, did not respond to the appeal of the traditional family feuds, and the nobles were more interested in the distribution of Church lands than in bands and conspiracies. The king was strong enough to punish private quarrels which led to disorder and bloodshed, and to dragoon the Highlands into something like obedience to the law. James, in governing Scotland, relied upon the Privy Council, but it was no part of his plan to establish a powerful bureaucracy, and it was the king's personal policy that the council carried out. But the experiences of his youth made him conscious of the limits of national acquiescence in a despotic rule.

The King's Victory over the Church.—That limit was most likely to be reached in ecclesiastical affairs. James was resolved upon transforming the titular episcopacy which he had established into an episcopate possessed of Anglican consecration and exercising real control over the clergy. His desire for episcopacy was purely political. He looked upon the form of church government as being, in itself, a "thing indifferent," but he held that church government in any State ought to harmonize with the civil government, and episcopacy agreed best with monarchy. His opponents, led by Andrew Melville, regarded episcopacy as unscriptural and therefore unlawful in a Christian Church, and believed Presbytery to be of divine institution. There was, therefore, no possibility of compromise, and, by a series of clever and unscrupulous tricks, James defeated the Presbyterian Party in the Church itself and secured complete control over the General Assembly. Parliament, which was always a facile instrument in his hands, passed in 1606 an act to acknowledge the sovereign authority of the Crown over all estates, persons and causes, ecclesiastical as well as secular, and repealed an act of 1587 which had annexed diocesan revenues to the Crown, thereby indirectly "abolishing the estate of bishops." In 1610 a General Assembly approved of an episcopal constitution of the Church, provided that the new bishops should be subject to the assembly. In the same year, James appointed bishops with Anglican consecration, and in 1612 parliament ratified the Acts of the Assembly of 1610, without reference to the authority of the assembly over the bishops. Such authority was, indeed, inconsistent with the powers enjoyed by the bishops both individually and in a court of high commission which James instituted on the English model.

Ecclesiastical Policy of Charles I.—The ecclesiastical policy of James VI., which did not include the abolition of the lower church courts of the presbyterian system, was successful. He had grafted bishops on to a Presbyterian Church, and, if no other considerations had intervened, his compromise might well have endured. He once disturbed it himself when, in 1618, he got a general assembly at Perth to sanction some innovations in ritual known as the Five Articles of Perth. This was the last occasion upon which he summoned an assembly; he intended that its place should be taken by the bishops. Parliament in 1621 ratified the Perth articles, though after an unusual display of opposition, and while the articles were willingly observed in the north-east, they led elsewhere to irreverent wranglings in church and to the deprivation of ministers and imprisonment of both ministers and laymen. In spite of some explosions of temper there are indications that James realized the danger, and, in his last years, refusals to conform to the Five Articles were frequently ignored. This cautious policy was at first maintained by Charles I. (1625–49), but when the new king visited Scotland for his coronation in 1633, he got parliament to pass an act ordering the clergy to wear white surplices in place of the Genevan black gown. In 1635 a Book of Canons for the Church of Scotland was issued by royal authority. The canons were intended to destroy the Jacobean compromise by making new provision for the discharge of the duties hitherto assigned to the lower presbyterian courts, and by making the government and ritual of the Church uniform with those of the Church of England. A prayer-book designed to supersede an optional service book which had been drawn up by John Knox was published in 1637, and the public use of *ex tempore* prayer was forbidden to ministers under pain of deprivation.

The National Covenant.—The challenge to Scottish custom thus made was ignorantly believed to be part of a scheme for the introduction of popery, and a riot against the new prayer-book in St. Giles's cathedral, Edinburgh, on July 23, 1637, proved to be the beginning of a revolution. The ecclesiastical quarrel came at a time when Charles had roused the opposition of the Scottish nobility by the provision which he made for the sustentation of the clergy and by the confidence which he reposed in the bishops, and when unusually heavy taxation had provided the middle classes with a grievance specially felt in Edinburgh, the burgesses of which had been forced to contribute to the erection of a new parliament house and to the expenses incurred in the foundation of the Bishopric of Edinburgh in 1633. It is possible that an immediate withdrawal of the prayer-book might have saved the situation, but Charles, in spite of warnings from the Privy Council, refused to give way, and his opponents formed an organization known as the Tables, which almost superseded the timorous Privy Council as the executive of the kingdom. In reply to a royal threat made in Feb. 1638, there was sent for signature throughout the country the National Covenant of 1638. It was the document to which James VI. had invited signatures in 1581, but it included an appended protest against recent innovations. Charles was at last alarmed and offered to withdraw the service book and to permit a free assembly and a free parliament to meet, but it was too late. The assembly was duly summoned, and it met at Glasgow in Dec. 1638. It proved to be a meeting of extreme Presbyterians—only Covenanters were admitted to its membership—and it defied the Royal Commissioner, pronounced sentence of deposition upon the bishops, and repealed all the legislation of former assemblies by which James VI. and Charles I. had established episcopacy.

THE CIVIL WAR AND THE COMMONWEALTH

The "Bishops' Wars."—An appeal to arms was inevitable, but the Covenanters (*q.v.*) were prepared for it and ready to send one army to force the Covenant upon the episcopal north-east and another to the Borders to meet such levies as Charles, then ruling England without a parliament, could raise. King and Covenanters met at Berwick in June 1639, and made a compromise by which the questions at issue were reserved for the decision of another parliament and assembly. Neither party was prepared to go to extremities. Charles was unwilling to summon an English parliament, without which he could not hope to coerce the Scots, and the Covenanters did not know what action an English parliament might take. The meeting of the Short parliament in the spring of 1640 convinced them that Charles had more to fear from an English parliament than they had, and when he was unwise enough to hesitate about carrying out the terms of the Pacification of Berwick, a Scottish force, under Alexander Leslie and the young earl of Montrose, invaded England in Aug. 1640 and occupied Newcastle. Charles had no force to bring against them, and by the Treaty of Ripon they remained at Newcastle, and a body of Scottish commissioners went to London to discuss terms of evacuation. The king at first hoped that the Scottish invasion would lead the Long parliament to give support to the Crown, but he soon found that the Commons regarded the Scots as allies, and, after the execution of Strafford, he tried to obtain Scottish support by yielding on all the points at issue. For this purpose he visited Scotland in 1641. He assented to the abolition of episcopacy, and agreed that the officers of State, the Privy Council, and the judges should be appointed with the sanction of the Scottish parliament. He showered honours upon his opponents, made the earl of Argyll a marquis and created Leslie earl of Leven. But, except for the adhesion of the earl (afterwards marquis) of Montrose, he failed to create a Royalist Party, and his visit was worse than useless.

The Solemn League and Covenant.—The royal surrender on all the points at issue left the Scots without any quarrel with Charles or any pretext for joining the English parliament in the civil war. But some Scottish ecclesiastics, who had been resident in London as Commissioners under the Treaty of Ripon, had become impressed with the Presbyterian atmosphere of the City of London and of the House of Commons, and had formed an ambition of establishing a Presbyterian uniformity between the Churches of England and Scotland. When, after the early campaigns of the civil war, both king and parliament asked for Scottish help, the advocates of this policy decided Scottish action. By the Solemn League and Covenant the Scots agreed to send an army into England to oppose the king, and the English parliament agreed to accept a reformation of the English Church. An assembly of English divines, with some Scottish assessors, was to meet at Westminster to settle the new constitution of the Church, but by the terms of the Solemn League, popery, episcopacy and schism (independency) were expressly excluded from the settlement. These terms included every known form of Church government except Presbytery, and, though the assembly of divines was nominally free to deal with the English ecclesiastical problem in its own way, it was really bound to accept the Presbyterian solution. The Scottish army, under Leven, made a substantial contribution to the parliamentary victory at Marston Moor, in July 1644, but the parliament, even with the help of the Scots, was unable to beat the royalists. That task was accomplished in 1645 by the New Model Army, but Cromwell and his soldiers were Independents, and though they, like other inhabitants of both England and Scotland, had been compelled to take the Solemn League, they were determined not to establish Presbytery as the only form of church government permitted in the island. Meanwhile, a large portion of the Scottish army was recalled to Scotland to defend the Covenanting parliament against Montrose, whose brilliant campaign in 1644–45 revived royalist hopes of victory. After Montrose's defeat at Philiphaugh (Sept. 1645) the king's cause was hopeless, and in May 1646 he surrendered to the Scottish army at Newark.

The Scots hoped to secure the assent of Charles to the Solemn League and a consequent union of king, parliament, and Scots against the army, but Charles, apart from his personal conscientious scruples, could not desert the Anglican Cavaliers who had fought for him. When he refused, the Scots surrendered him to the parliament, on condition of payment of part of the arrears due to the Scottish army for its expenses in the war. The development of events in England made it clear that the parliament could not fulfil the terms of the Solemn League, for power passed from the two Houses to the army. Chagrined at the failure of the scheme of a covenanted uniformity, under which Scotland had already abandoned its own Catechisms and Confession of Faith in favour of the documents produced by the Westminster Assembly of Divines, the Scottish parliament in 1647 entered into what was known as the Engagement with the king, then a prisoner in the Isle of Wight. The General Assembly with which the parliament had hitherto acted in harmony, strongly disapproved of this agreement by which Charles was to allow a three years' trial of the establishment of Presbytery in England—an insulting suggestion for what the Scots held to be a divine institution. The quarrel between Engagers and Anti-Engagers affected Scottish history for years to come. The army under the duke of Hamilton which, in accordance with the Engagement, invaded England, was defeated by Cromwell at Preston in Aug. 1648. The victory was also a triumph for the assembly over the parliament, and the Anti-Engagers, led by the marquis of Argyll, entered into friendly relations with Cromwell, and, obtaining a parliamentary majority, proscribed the defeated Engagers in the statute known as the "Act of Classes" which placed them in a class or category with the royalists as men incapable of holding any civil office or serving in the army.

Cromwell.—The execution of Charles I. created a revulsion of feeling in Scotland, and a proclamation of Charles II. as King of Great Britain offered defiance to the new English Commonwealth. The Scots, however, would not receive Charles in Scotland or give him regal authority until he signed both the National Covenant and the Solemn League. He hesitated for some time, but the execution of Montrose, who was captured after an abortive invasion in 1650, convinced him that he had no alternative but subscription to the Covenants, and he landed at the mouth of the Spey in June 1650, to find himself practically a prisoner in the hands of the Anti-Engaging section of the Covenanters. The defeat of the Scottish army by Cromwell at Dunbar (Sept. 3, 1650) went far to destroy the influence of the assembly and the Anti-Engagers, and not only Engagers, but even royalists, were exempted from the Act of Classes by a series of public resolutions passed in parliament in 1651. These resolutions produced a fresh division between Resolutioners and Protesters or Remonstrants. The breach thus produced survived the defeat of the army which Charles II. led to Worcester (Sept. 3, 1651) and also the rule of the Commonwealth and Protectorate.

For nearly nine years Scotland was under a military occupation, though the naked rule of the sword was partially disguised by the admission of Scotland into the United Commonwealth of England, Scotland and Ireland. Scottish administration, under Gen. Monck, was vigorous and efficient, but the impoverished condition of the country prevented it from reaping the full benefit either of the restoration of law and order or of the institution of free trade with England and the English colonies. The civil war, followed by Cromwell's campaigns, had serious economic results which were aggravated by the confiscation of royalist estates and by the introduction of a burdensome system of taxation, which, however, did not nearly cover the expenses of administration. On the religious side, the Cromwellian Government forbade the general assembly to meet, and insisted upon a toleration of Independents.

RESTORATION AND REVOLUTION

The Second Episcopacy.—Though the Protectorate was unpopular, Scotland had no direct share in the Restoration and merely accepted the accomplished fact. The chief problem of Charles II. (1660–85) and his ministers was the religious question. Presbytery was legally established in Scotland by acts of parliament to which Charles I. had given the royal assent, and the new king began his reign by promising to "protect and preserve the government of the Church of Scotland as it is settled by law." But a Scottish parliament passed in March 1661 a General Act Rescissory which annulled all legislation since 1633, and episcopacy automatically became the government of the Church "as settled by law." Scottish bishops were appointed, but Charles II. did not follow his father's example in prescribing a prayer-book or in superseding the lower courts of the church, which were placed under the supervision of the bishops. But lay patronage of livings was restored by the repeal of an act of 1648 which had abolished it, every one admitted to office of any kind had to renounce the covenants, and penalties were prescribed for preaching (or praying in public) against the episcopal government of the church. A few years later fines were imposed for non-attendance at parish churches, lists of absentees were required from the incumbents, and soldiers were quartered in non-conformist districts to collect the fines.

The result was that conscientious Presbyterians began to worship in secret conventicles, and further repressive measures were therefore necessitated. Ejected ministers were forbidden to reside within 20 miles of their former parishes, and masters, and even landlords, were held responsible for the attendance, at such field-meetings, of their servants or tenants. A rebellion was expected by the Government, and it came in the end of 1666. It originated in the south-west; and the insurgents marched upon Edinburgh, but were easily defeated at Rullion Green in the Pentland Hills. A cruel vengeance was taken by the Privy Council, the president of which, James Sharpe, had deserted the Presbyterian cause in order to become Archbishop of St. Andrews. Under the first two royal commissioners through whom Charles II. ruled Scotland the earl of Middleton and the earl of Rothes, the bishops had exercised a powerful influence over the administration. The next commissioner, the duke of Lauderdale, who was in power from

1667–79, disliked the episcopal system which he was bound to maintain and his jealousy of the influence of the bishops was illustrated by his insistence upon the royal supremacy over the Church. He began his rule by treating the recalcitrant Covenanters more mildly, but an increase in the number of conventicles was followed first by savage measures of repression and then by a renewal of efforts at conciliation. These again failed and Lauderdale, like Rothes, began to desire a rebellion. He had his wish, but the result was his fall from power.

Bothwell Bridge and Drumclog.—On May 3, 1679, Archbishop Sharpe was murdered by a small body of fanatics. A few years earlier the murder would have been an isolated outrage, but Lauderdale's measures had created sympathy for the murderers, and on May 29 some 80 Covenanters at Rutherglen proclaimed their defiance of the king. They collected an army which was unsuccessfully attacked by James Graham of Claverhouse (afterwards Viscount Dundee) at Drumclog on June 1, and, flushed with victory, they marched on Glasgow but failed to enter it. For three weeks they held the country round Hamilton. An organized movement would have been a serious matter for the Government, but the rebels were looked upon by the majority of the Presbyterians as extreme fanatics and only a few outlaws joined them. On June 22 the duke of Monmouth defeated them at Bothwell bridge. Both by instinct and from policy, Monmouth was inclined to leniency, but he was soon replaced by the duke of York, who ruled, with intervals of absence, during the years 1680–2. York had some ideas of moderation and his encouragement of trade does him some credit, but the period of his rule was distinctively known as the Killing Time. Parliament put the penal laws passed against Roman Catholics into force against the Covenanters, and by the Test Act it imposed upon all persons in public trust an oath which emphasized the royal supremacy over the Church so strongly that 80 of the episcopal clergy gave up their livings rather than take it. After York left Scotland, things grew worse, and the torture of the thumbscrew was called in to supplement the use of another instrument of torture, the boot.

The Reign of James VII.—When the duke of York succeeded to the throne as James VII. (1685–88), the earl of Argyll, an exile under sentence of death for a "treasonable" refusal to take the Test Act, raised a rebellion in combination with Monmouth. He landed in Argyll and crossed to the neighbourhood of Glasgow, where his small army quarrelled and dispersed; its leader was captured and executed. The rising gave the Government little trouble, but it was the excuse for a ferocious act which appointed a death penalty for mere attendance at a conventicle. The Tory Parliament which passed this act could not, however, in its second session (1686), be persuaded to accept a measure for toleration of Roman Catholics, upon which the king had set his heart. James, therefore, resolved to employ the royal prerogative for this purpose as he was doing in England, and in 1687 he issued a Declaration of Indulgence which brought the Killing Time to an end. Fear of popery diminished the gratitude felt for this boon, and in 1687–8 the measures adopted by James to place Roman Catholics at the head of affairs raised widespread alarm. But the Revolution, like the Restoration, was distinctively an English movement, and it was not until the prince of Orange had been for more than a month on English soil, that a body of Edinburgh rioters sacked Holyrood, which had been given as a place of Roman Catholic worship and education. In various districts in the south and south-west bands of ruffians "rabbled" the manses of the episcopal clergy.

A Convention of Estates, summoned by the prince of Orange, met in April 1689, and, by a majority, declared that James had forfeited the Crown. It was offered to, and accepted by, William and Mary and entailed upon their issue and then upon the Princess Anne and her issue. Stipulations similar to those of the English Bill of Rights were made, and the new sovereigns had to accept another limitation; viz., that prelacy was an insupportable grievance and ought to be abolished. The Crown was accepted on these conditions and the convention was converted into a parliament in June. But the promised abolition of episcopacy turned the Scottish episcopalians into a Jacobite Party, and, in the early summer of 1689, Edinburgh Castle was holding out timorously for King James, and Viscount Dundee was raising an army to carry out a famous threat which he had made to the convention. The castle surrendered on June 13. On July 27 Dundee was killed in the hour of victory at Killiecrankie. With his death, the danger of a Jacobite restoration came to an end. Presbytery was re-established in 1690, and the general assembly met that same year. for the first time since 1653.

The Massacre of Glencoe.—The reign of William was marked by two serious disputes, which embittered feeling between Scotland and England. The Highlanders were opposed to the revolution settlement, and the Government, apprehensive of a French invasion, tried by money payments to induce the chiefs to take the oaths to William and Mary. Dec. 31, 1691, was fixed as the last day on which the submission of the recalcitrant chiefs could be received; those who had not qualified by that date were to be liable to the terrors of the law. Alexander MacDonald of Glencoe delayed his acceptance of the terms to the last moment, and then presented himself before a Government official who was not authorized to administer the oath. Owing to this accident, he did not take the oath until January 6. The Under-Secretary of State, Sir John Dalrymple, Master of Stair, was glad to have an opportunity of making an example, and, in accordance with precedent, "letters of fire and sword" were issued against the MacDonalds of Glencoe. The penalty contemplated by the law seems to have been the expulsion of the clan from its territory and a consequent dispersion of its members, as the MacGregors had been rooted out and scattered in the reign of James VI. But the Government devised a scheme of murder committed in circumstances of revolting treachery. A small body of troops, under Campbell of Glenlyon, was sent to Glencoe, and the soldiers were for nearly a fortnight the guests of the clansmen, while Glenlyon was arranging to guard the passes by which his hosts might escape. Shortly after midnight on Feb. 12-13, 1692, the signal for a massacre was given. The military plans miscarried and a large proportion of the MacDonalds escaped (some of them to perish from cold and exposure), but between 30 and 40 were murdered. The crime evoked an indignation which indicates the development of a sympathy for the Highlanders that had been foreign to Lowland feeling for more than a century, and the Jacobites naturally availed themselves of it for political purposes, but it was not till 1695 that the Scottish parliament demanded an enquiry and, on receiving an official report, voted that "the killing of the Glencoe men was a murder." The responsibility for the crime lay with William's Scottish ministers, but the king was guilty (in Macaulay's words) of "a great breach of duty" in shielding the Master of Stair from any punishment beyond dismissal from the Secretaryship of State which he held in 1695, and the massacre of Glencoe contributed to the rise of an anti-English feeling even in the Lowlands.

The Darien Scheme.—Another tragedy of William's reign was much more directly attributable to English influence. Scottish commerce, which had been seriously affected by the civil war, the Dutch wars, and the war with France, was attempting to find new outlets, and William Paterson, the founder of the Bank of England, suggested a project for the colonization of the Isthmus of Darien. The scheme involved a challenge to Spain, which claimed the territory on which the Scottish emigrants were to settle, but the "African Company" formed to trade with Africa and the Indies, received a charter conferring powers of military colonization as well as trading privileges. The venture was unfortunate from the first. A strenuous and remarkable effort made by the Scots to raise capital was to be supplemented by English subscriptions, but the jealousy of English merchants was aroused, and the House of Commons compelled the withdrawal of the English shareholders. The Scots persevered and in the end of 1698, about 1,200 Scottish colonists landed in the pestilential region of Darien. There were two further expeditions, but disease, famine and Spanish attacks combined to render the adventure hopeless. At the time the chances of preserving peace in Europe depended upon William's successfully negotiating the Partition

Treaties, and he could not give the Scots support against Spain. In March 1700 the remnants of the Scottish colony evacuated Darien; their vessels were shipwrecked and few of the survivors reached home. It was the greatest disaster in Scottish commercial history, and the calamity which had overtaken the nation was ascribed to English hostility and to the refusal of William to maintain the privileges originally granted to the African Company.

THE UNION

The Constitutional Position After the Revolution.—When William died, in March 1702, the hostility between England and Scotland was so bitter that the continuance of a Union of the Crowns after the death of Queen Anne was in danger. The revolution settlements in the two countries had, in fact, made the existing constitution unworkable. Before 1689, the Scottish parliament, except during the civil war (1638–51), had exercised only a slight influence upon the national history. It was much less representative than the English House of Commons, and its methods of procedure were such as to make it a tool in the hands of the Government. Its efficient powers were entrusted to a committee known as the Lords of the Articles, which, though consisting of members of parliament, was not elected by the whole House. The choice of its members was manipulated by the Government and on many occasions a majority of its members were also members of the Privy Council, the executive of the country. But, after the revolution, the Committee of the Articles was abolished, and the Scottish parliament, having secured the rights for which the English parliament had long contended, could compel the sovereign to act in accordance with its demands in domestic affairs, and claimed also to control foreign policy. In the days of personal government, a monarch ruling over two independent kingdoms had no difficulty in securing unity of policy, but the new constitutional monarchy found it hard to reconcile the aims of two separate parliaments. A mere union of the Crowns could not suffice to meet the necessities of government.

Proposals for union had been made on several occasions since 1603. James VI. had tried to bring about a complete incorporating union with "one worship of God, one kingdom entirely governed [*i.e.*, with a single government], one uniformity of law," but had been compelled by the opposition of the English Commons to abandon his projects. Cromwell had forced a union upon the Scots, and, after the Restoration, they suffered from the loss of the trading privileges which a union had involved. In 1667 commissioners from the two countries met to negotiate a commercial treaty, and when the English commissioners refused to exempt Scotland from the operation of the Navigation Act, Charles II. proposed a scheme of union which was discussed in 1670, but without result. At the revolution, the Scottish parliament itself appointed commissioners "to treat the terms of an entire and perpetual union between the two kingdoms," but though William did his best to encourage the scheme, his English parliament would not appoint English commissioners. William remained an enthusiastic advocate of union, and recognized in the bitter temper of both nations after the failure of the Darien scheme a reason for accelerating it. But again (1700) the English Commons would not agree to the appointment of a commission, and William, from his deathbed in 1702, sent a royal message to the English parliament urging the necessity of a union for the preservation of peace between the two countries. As a mark of respect for his memory, Anne invited the two parliaments to appoint commissioners. A commission sat in the winter of 1702–3, but the negotiations failed because of the opposition of the English merchants to a scheme which involved reciprocal freedom of trade.

The Problem of Union.—A union was recognized to be desirable both for constitutional and for commercial reasons, but it was a political necessity that compelled the ministers of Queen Anne to take further action. In spite of the Act of Settlement, the Hanoverian succession could not be regarded as safe even in England. The Scots had made no settlement of the Crown after the death of Anne, and a Jacobite triumph in Scotland, on the occurrence of that event, would have meant a large increase of strength to the English Jacobites. It was therefore essential to bring about, in Anne's lifetime, a complete incorporating union on the basis of the Protestant succession, so that there would be, on the Queen's death, no legal means whereby the Scots, by themselves, could alter the succession. Such a union must involve freedom of trade, and to this the English Whigs, largely composed of the mercantile classes, were opposed. In Scotland, the desire for a union which had been shown in 1689 had almost entirely disappeared, and its vehement opponents included not only the Jacobites but also a "Patriot" or "Country" Party, led by Andrew Fletcher of Saltoun, which championed the independence of Scotland from French and English influence alike. A combination of Jacobites and Patriots brought about in 1703–4 a dangerous legislative warfare between the two parliaments, and an outbreak of hostilities between the two nations was well within the bounds of possibility.

The English Whig ministry, strengthened by Marlborough's victory at Blenheim, resolved to defy the prejudices of their own supporters and to offer a union on the basis of freedom of trade combined with securities for the safety of the Presbyterian Established Church and for the maintenance of Scots law and of the Scottish Courts of Justice. The Scottish Whigs responded to the offer and commissioners from both countries met in April 1706. The subject which gave rise to most discussion was the representation of Scotland in the future parliament of Great Britain. The numbers as finally settled gave Scotland the inadequate representation of 45 members in the Commons and 16 in the Lords. In Jan. 1707 the proposed Treaty of Union was confirmed by the Scottish parliament by a majority of 110 votes to 68, and the terms were embodied in legislative measures carried by each of the two parliaments. The union was distinctly unpopular, but the Jacobite assertions that it was carried by bribery have been challenged.

THE JACOBITE RISINGS

"The Fifteen."—The first General Election for the British parliament (1708) gave something like national sanction for the Union, possibly because of the alarm caused by an attempted French invasion in the beginning of the year. But the process of carrying out the financial provisions of the Union caused considerable friction; the Scots resented the introduction into Scotland of the English law of treason, and the Presbyterians disliked a grant of toleration to Scottish Episcopalians and had more reasonable ground for indignation at the restoration of lay patronage in the Church. It had been abolished in 1690, and the patrons had been compensated, and the act of 1712 was a breach of the agreement made at the Union. Thus, by Anne's death in 1714, the party which had brought about the Union seemed to have suffered most from its effects. It was the strength of Protestant feeling among the Scottish Whigs that prevented these disappointments from bringing large reinforcements to the Jacobites on the accession of George I. The Tory ministers of the end of Anne's reign had been suspected of an intention of restoring the Stuarts in the person of the Old Chevalier, then a man of 26, and the Whig ministry of George I. was supported, in the election held at the beginning of 1715, by a large proportion of Scottish Whigs. In the same summer the earl of Mar raised the first Jacobite rebellion, but failed to win Lowland support, except in the north-east, which had always been a stronghold of episcopacy. "James III. and VIII." was proclaimed at Aberdeen, and Mar led his army to Perth. But the death of Louis XIV. led to the withdrawal of French support which had been promised, and Mar, instead of marching at once upon Edinburgh, remained at Perth till Nov. 10. On Nov. 13 his march upon Edinburgh was intercepted by Government troops under John, duke of Argyll, at Sherifmuir, near Dunblane, and, though the battle was technically a drawn one, it compelled Mar to retire to Perth. A rising in the north of England was defeated on Nov. 14, the day after Sherifmuir. James, who had been prevented by the change of policy in France from joining his troops, landed near Peterhead on Dec. 22, spent three weeks in Perth, and then fled with Mar to France.

Argyll proved a merciful victor and the number of executions

was only about 30, but some hundreds of prisoners were transported to the American colonies, and many of them were tried, under an act of parliament passed for the purpose, at Carlisle, Scottish juries, even in the lowlands, being unwilling to find them guilty. The sale of confiscated Jacobite estates involved injustice to innocent sufferers, but an Act of Indemnity was passed in 1717. In order to provide for future emergencies, Gen. Wade was entrusted with the task of constructing roads in the Highlands, the military purpose of which did not diminish their economic value. A new Jacobite attempt was planned for 1719, and aid was promised by Sweden, but the death of Charles XII. prevented the fulfilment of the promise. An outbreak of war between Great Britain and Spain in 1718 raised hopes of Spanish help, but the Spaniards sent only a small raiding force. The Spaniards were joined by a few Highlanders and were defeated at Glenshiel (June 1719).

The Porteous Riots.—During the long rule of Walpole (1721–42), the gradual growth of trade and commerce began to reconcile Scotland to the Union, but the period was marked by two outbreaks of violence. A tax upon malt roused so much Scottish opposition that it was only after some years that the authorities, in 1725, attempted to enforce it. There were fierce riots in Glasgow when excise-officers tried to enter the malt houses, and the Edinburgh brewers, encouraged by the mob, announced their intention of refusing to brew with taxed malt. This remarkable form of "strike" lasted for a week, and, in the end, Scotland paid the tax and enjoyed its beer. A more famous Edinburgh riot has been immortalized in *The Heart of Midlothian.* Two smugglers under sentence of death made an effort to escape, and one of them succeeded in doing so with the help of the other, a man named Wilson. The sympathy generally felt for smugglers was increased by the circumstances, and the City Guard, under Captain Porteous, was warned to expect an attempt to rescue Wilson at his execution. There was no attempt at rescue, but, after the execution, the mob attacked the guard, who fired and killed a small number of onlookers. Porteous was sentenced to death for murder, but Queen Caroline, who was regent during an absence of George II. in Hanover, granted a reprieve for six weeks and was believed to intend to follow the reprieve by a pardon. On the night of the day originally fixed for the execution (Sept. 7, 1736), a mob broke into the Tolbooth prison, seized Porteous and hanged him on a dyer's pole. There was no riot in the ordinary sense of the word, and the murderers of Porteous were never detected.

Prince Charles Edward and "the 'Forty-five."—The Jacobite movement in Scotland was, by this time, moribund, but it was galvanized into activity by the ambition of the young Prince Charles Edward to recover the throne which his grandfather had lost. Walpole had always believed that the exiled house would make another attempt, and this belief had been one of his reasons for maintaining a policy of peace. After his fall, the existence of hostile relations with Spain and France afforded an opportunity for which Jacobite exiles had been watching. The French Government assembled troops for an invasion of Scotland in 1744, but a storm destroyed their transports, and, in July 1745, Charles Edward was allowed to try his fortune without any French aid except a small quantity of munitions. The adventure was inspired by exiles and there was no enthusiasm for it in Scotland; Charles had to persuade even the Highland chiefs to join him, and he was not always successful. The troops he commanded were never so numerous as the army which Mar had collected 30 years before. The charm and daring of the young prince, and the absence of Government troops on the Continent, produced, however, a much more dangerous and a much more dramatic result than that of "the 'Fifteen."

The commander-in-chief in Scotland, Sir John Cope, instead of guarding Edinburgh, marched to intercept the prince and his Highlanders, but, probably wisely, refused a chance of giving him battle, and the Jacobite force made its way to Edinburgh. On Sept. 17, Charles, as prince-regent of the three Kingdoms, took up his quarters in Holyrood. Cope, having marched to Inverness and thence to Aberdeen, took ship to Dunbar, disembarked his troops and was immediately defeated at Prestonpans (Sept. 21). The prince expected this success to be followed by a large adhesion of followers, but he waited in vain at Edinburgh for the expected recruits. Then, deciding to attempt a march upon London, he crossed the Border on Nov. 9, hoping to be joined by the Lancashire Jacobites. His expectation was again disappointed, but he continued his southward march as far as Derby (Dec. 4). By that time troops had been recalled from the Continent, the duke of Cumberland was at Lichfield with one army, and Marshal Wade commanded another in the north of England. Charles had reluctantly to accept the opinion of his officers that a further advance was useless, and the retreat began on Dec. 7. The Jacobites marched by Carlisle and Dumfries to Glasgow, and thence to Stirling, where they besieged the castle. On Jan. 17, 1746, the prince attacked a relieving force under Gen. Hawley at Falkirk and won his second and last victory. The state of feeling in the Lowlands rendered a further retreat inevitable, and Charles, having taken Inverness and Fort Augustus, indulged in hopes of help from France. It did not come, and on April 17 Cumberland destroyed the Jacobite army on Culloden Moor. The prince, after many adventurous wanderings, escaped to France in September. The ferocity with which Cumberland treated the prisoners gained him his nickname of the Butcher. The Government had been desperately alarmed, and less mercy was shown than in 1716. About 80 Jacobites were executed, and the Highlanders were forbidden to carry arms, to wear their distinctive dress, or to play the bagpipes; the prohibition of the kilt was maintained until 1782. The part played by the Episcopalians of the north-east in the rising led to acts which punished with transportation for life any Episcopal clergyman who did not pray in express words for King George, denied protection under the Toleration Act of Queen Anne to clergy ordained by Scottish bishops, and subjected to fine and imprisonment laymen who attended services held by such clergy. This attempt to restrict toleration to Scottish Episcopalians who were members of the Church of England was not abandoned until 1792.

The results of the suppression of the "Forty-five" were, however, not all evil. The abolition of hereditary jurisdictions in 1747 was a reform long overdue, for the administration of justice by magistrates whose tenure of office was not dependent upon the central government was incompatible with good administration. The owners of the hereditary jurisdictions received compensation, and many of them used the money to effect great improvements in agriculture. The period marks a new era in the history of Scottish farming. A few years later, William Pitt tried the successful experiment of raising two regiments of Scottish Highlanders for the army. This device had been suggested to Walpole by Duncan Forbes of Culloden, a statesman whose influence afterwards prevented some of the clans from joining Prince Charles, and Walpole had recognized its wisdom, but had been prevented from acting upon it by parliamentary dislike to an increase of the standing army.

REFORM

Scotland Under George III.—During the reign of George III. the history of Scotland merges in that of the United Kingdom, in the politics of which Scotland began to take a prominent part, and only a few points need be mentioned. It was a disgrace to the country that, in the second half of the 18th century, servile conditions still existed in coal-mines and salt-pits. The old feudal serfdom had died out earlier in Scotland than in England, and a judicial decision in 1775 had declared that a slave brought to Scotland was thereby emancipated, but, in spite of this, workers in coal-mines and salt-pits remained under ancient obligations scarcely distinguishable from serfdom. Having once entered a mine, at however early an age, a miner was bound to remain at work there to the end of his life, and his services were sold along with the mine in which he worked. Henry Dundas, who was the actual, though not the official, minister for Scotland almost continuously from 1775 to 1801, abolished this evil system by acts passed in 1775 and 1799. His period of rule witnessed a large extension of Scottish commerce, in spite of a check to the pros-

perity of the rapidly growing city of Glasgow through the American War and the repudiation of American debts to Great Britain after the Declaration of Independence. The Forth and Clyde canal was begun in 1768 and other canals, roads and bridges were constructed in various parts of the country. The outbreak of the French Revolution, which soon put an end to the short period of peace that followed the American War, at first created considerable sympathy in Scotland, but, as the violence of the revolutionaries progressed, the sympathy became confined to the Societies of the Friends of the People, which, like similar Societies in England, began to demand universal suffrage and annual parliaments. A convention of delegates from these societies, held at Edinburgh in Dec. 1792, was followed by the trial of Thomas Muir for sedition. The development of events in France brought about a panic, and it is admitted that Muir did not have a fair trial; he was sentenced to transportation for 14 years. A similar convention in the following year was believed to contemplate inviting foreign troops into the country and was suppressed by the authorities, but the seditious element among the Friends of the People was very much smaller than the Government imagined. Most of them were constitutional reformers who advocated changes which had received considerable support before the massacres in France created a general aversion to any alteration in the constitution. The fear of sedition, fed by the activities of a small number of extremists, continued throughout the first years of the Great French War, and volunteers were enlisted in 1794 for the preservation of order at home as well as for defence. The most important political event which affected Scotland during the war was the impeachment of Henry Dundas, Lord Melville, in 1805. He was acquitted in the following year, but his prosecution introduced into Scottish politics an intense bitterness, illustrations of which may be found in Lockhart's *Life of Sir Walter Scott.*

The Reform Acts.—After the conclusion of the war, Scotland shared in the discontent of the troubled years 1815–20, and the name of the "Radical War" has been given to a series of political riots in Paisley, Glasgow and Greenock in 1819–20; the Government again over-estimated the danger of an outburst which was closely related to unemployment and agricultural distress. In the reign of George IV. (whose visit to Edinburgh in 1822 was the first state visit of a sovereign to Scotland since the time of Charles I.) the discontent passed into a constitutional agitation for parliamentary reform. The representation of Scotland in the British parliament had been settled in 1707 on the lines of the then existing system. The country electorate was so small that, in 1822, when the population of Scotland was nearly 2,100,000, the total number of county voters was under 3,000. The burgh members were returned by the town councils, themselves self-elected bodies. The Reform Act of 1832, which added eight to the number of Scottish members, extended the franchise in the counties to owners of lands or houses of the yearly value of £10 and to certain classes of tenants. In the burghs a vote was given to occupiers of houses valued at £10 a year. Further extensions were made, as in England, by the Reform Acts of 1867–68 and 1884–85. The change made by the act of 1832 is illustrated by the circumstance that Scotland, which in 1831 returned 24 Reformers and 21 anti-Reformers, sent to the first Reformed parliament 41 Whigs and 12 Tories. That parliament passed in 1833 a Scottish Burgh Act which swept away the old corrupt burghal constitutions, against which Reformers had been waging war for nearly half a century, and restored to the citizens a long-lost right of electing their own municipal rulers.

19TH AND 20TH CENTURIES

The Church.—The middle of the 19th century was marked by a great ecclesiastical struggle, culminating in 1843 in the disruption of the Church of Scotland and the foundation of the Free Church. After 57 years of separate existence it united in 1900 with the United Presbyterian Church, itself an amalgamation of small churches which had seceded from the Church of Scotland, frequently on some dispute connected with lay patronage, an institution which troubled Scotland from the passage of the Patronage Act of 1712 until the repeal of that act in 1874. A minority of the Free Church disapproved of the Union of 1900, and their claim to retain the property of the church was upheld, on appeal, by the House of Lords in 1904. The obviously inequitable character of the legal decision led to the appointment of a royal commission to allocate the property between the Free Church and the United Free Church, and its recommendations were embodied in an act of parliament in 1905 (*see* SCOTLAND, CHURCH OF).

A movement for a still wider union of the Presbyterian Churches in Scotland began about 1912. Negotiations between the Church of Scotland and the United Free Church were interrupted by the World War, and, after their resumption, the Church of Scotland obtained in 1921 an act of parliament the effect of which was to transform the relations of the Established Church with the State and to give the church liberty both "to adjudicate finally in all matters of doctrine, worship, government and discipline," and to interpret and modify (within the limits of Trinitarian Protestantism) the Articles of the Constitution, which were scheduled in the act. This legislation removed the historical difficulties which, in conjunction with patronage, had led to the disruption of 1843, but it was felt that the system of endowment also required readjustment, after the lapse of nearly three centuries since it was settled by Charles I. This object was effected by the Church of Scotland (Property and Endowments) Act of 1925, and a body of Scottish Ecclesiastical Commissioners was appointed to give effect to a number of its provisions, including the transfer of endowments to general trustees of the Church. The two acts of 1921 and 1925 were promoted by the Church of Scotland avowedly for the purpose of removing "the main causes keeping the two Churches apart," and, while the act of 1925 was passing through its last stages in parliament, the general assembly of the United Free Church passed, by a majority, a resolution recognizing the progress achieved in this direction. The General Assemblies, both of the Church of Scotland and of the United Free Church, in 1928 gave definite approval to the basis of a scheme for union, to be constituted in 1929 or 1930.

Poor Law and Education.—Two years after the disruption, a Poor Law was introduced into Scotland. Up to 1845, the relief of the poor had been entirely in the hands of the Kirk Sessions of the various parishes, which possessed, but seldom used, powers of local taxation for the purpose. Social and economic developments, as well as the ecclesiastical separation produced by the disruption, necessitated a change in the traditional methods, and a Poor Law (Scotland) Act was passed in 1845. It followed in many respects the English Act of 1834 and established parochial boards under a central Board of Supervision, but it did not impose the English workhouse test, though it forbade relief to able-bodied poor. A Compulsory Education Act followed in 1872. Acts of the Scottish parliament had long ago ordered the provision of a school in every parish, but at the beginning of the 19th century this requirement had not been universally fulfilled, though educational facilities were better than in England. There was a considerable advance in the early 19th century, and from 1833 Scotland received a parliamentary grant for education. It was entrusted to the church, which remained in control of the schools; the Free Church, after 1843, established schools of its own. Church control was diminished by more direct Government supervision in 1861, and, after the act of 1872 was passed, the Presbyterian churches gave up their schools to the newly established School Boards. The Scottish Episcopal Church and the Roman Catholic Church retained voluntary schools until the Education Act of 1919 replaced the School Boards by education authorities elected over a wider area and made provision for the transfer of voluntary schools. The teachers in such transferred schools are, in accordance with the act, appointed by the local authority after being approved, as regards character and religious belief, by the denomination concerned. Electors to education authorities are persons registered as local government electors, and voting is conducted on the principle of proportional representation. Education authorities are empowered to expend money on the provision of food and books for children, and also to give assistance to qualified persons attending a university or training

college. This last provision has been followed by a large increase in the number of students at the Scottish universities. The act contemplated an extension of the compulsory school age to 15 years and an elaborate system of continuation schools, but its provisions have only been partially carried out.

The Scottish Secretaryship.—The administration of Scotland has been conducted since 1885 by a Secretary for Scotland, and since 1926 by a Secretary of State for Scotland. Soon after the Union of 1707, an additional Secretary of State had been appointed for Scottish affairs, and this arrangement continued until 1746, except for an interval from 1725–42, during which Scotland was governed nominally by one of the other two Secretaries of State, but really by Lord Islay, afterwards duke of Argyll. In 1746, in the middle of the Jacobite Rising, the Secretary of State for Scotland was involved in an intrigue against the Prime Minister, and had to resign. His place was not filled, and till 1885 Scotland was under the charge of the Home Secretary, who was always advised by some unofficial "Minister for Scotland"—in the later portion of the period, the Lord Advocate. The government of Scotland by a law officer, under the supervision of the Home Secretary, was an arrangement which could not survive the wide extension of governmental action and responsibilities which took place in the 19th century, and the arrangement was resented in Scotland. A Scottish National Convention, held in Edinburgh in 1884, demanded the creation of a Scottish Office, and in 1885 an act was passed creating a Scottish Secretaryship. In 1926 the office was raised to the dignity of a Secretaryship of State, during the tenure of office of Sir John Gilmour.

The World War.—Scotland was only slightly affected by the military operations of the war; considerable damage was done at Edinburgh by a Zeppelin raid on April 2, 1916, and the remote island of St. Kilda was bombarded by German naval units on Nov. 21, 1918. But, for the first time in history, the main activities of the Grand Fleet were conducted in Scottish waters, from Aug. 1914 to the surrender of the German fleet on Nov. 21, 1918. It was in Scapa Flow that the crews of 70 German men-of-war scuttled their ships on June 21, 1920; some of them have since been salved. The Clyde took a large share in British naval construction, and in various districts munition factories came into existence—the largest was built at Gretna in 1915. The expansion of industry during the war period and its diversion to unproductive activities had effects which were seriously felt after the conclusion of peace. The country, and especially the "heavy" industries in the Clyde valley have experienced the deepest and longest depression of trade in their history, and it is also in the Clyde area that the shortage of houses has been most severely felt. The failure of Scottish local authorities to solve the housing problem led to Government intervention at the end of 1925, and, since then, considerable progress has been made.

Political.—Since the conclusion of the World War a great change has occurred in the political complexion of the country. The Representation of the People Act (1918) increased the number of electors from 800,448 at the General Election of Dec. 1910 to 2,211,178 at the General Election of Dec. 1918. With the change in the electorate came a break in the traditional fidelity of Scottish constituencies to the Liberal party. In Dec. 1910 Scotland returned 58 Liberal, 11 Conservative and three Labour members; in 1918, when a proportion of Liberals supported the Coalition Government, there were 58 Coalition, seven Liberal, seven Labour and two Independent members. After the break-up of the Coalition in 1922 the Liberals held 28, Labour 29, and Unionists 15 seats; in 1923 the figures were 22, 35, and 16 respectively; and in 1924 the Liberals were reduced to nine and Labour 24, while the Conservative holding was increased to 40. During 1922–24 Motherwell was represented by a Communist.

The electorate in 1929 had increased to 2,937,067 and of the 74 seats Labour held 37, the Unionists 22, and the Liberals 14, while one was represented by an Independent Prohibitionist.

A Local Veto Experiment.—An important experiment in social legislation was tried in 1920, in accordance with the provisions of the Temperance (Scotland) Act of 1913, which provided that local authorities, on the receipt of signed requisitions from electors in their areas, should take a poll on three alternative resolutions dealing with the number of licences to sell alcoholic liquors in an area, viz., (1) that there should be no change in the system of licensing; (2) that the licensing court should grant not more than 75% of the licences previously in existence; (3) that all licences in the area should be withdrawn. Polls were taken in 584 out of 1,221 polling areas; in about 300 of the remaining areas no licences were in existence in 1920. Five hundred and nine areas voted for no change, 35 for limitation, and 40 for no licence. The contest of 1920 was fought by the Temperance Party upon a prohibition programme, and the result was rather a repudiation of prohibition than an indication of satisfaction with existing licensing conditions. Subsequent polls taken on requisitions made in accordance with the act of 1913 have not seriously modified the results ascertained in 1920, and it has been generally felt that the act requires amendment, especially in the definition of an "area" as a single ward in the larger burghs, which must be treated as a whole in order to render possible a more equal distribution in any reduction of licences; in Glasgow, the withdrawals of licences after the polls of 1920 were chiefly in middle-class residential districts.

The most important municipal developments have been the inclusion of the burghs of Govan, Partick, Pollokshaws, and some suburban districts within the city of Glasgow by an act of 1912, and a further extension of Glasgow municipal boundaries by an act of 1925; the amalgamation of Edinburgh with Leith, and the absorption of the suburban districts of Liberton, Colinton, Corstorphine and Cramond by the city of Edinburgh in 1920; and the amalgamation of Motherwell with Wishaw in 1920. There has been a remarkable series of gifts of historical buildings to the nation, including Dryburgh abbey by the late Lord Glenconner; Melrose abbey by the duke of Buccleuch; the farm of Ellisland (occupied by Robert Burns from 1788–91); and Duddingston Loch, near Edinburgh. Other buildings, including Kelso abbey, Inchcolm abbey and Restenneth priory, have also been placed under national custody.

The National Library.—The greatest of these gifts was made by the Faculty of Advocates in 1925. The library of the Faculty of Advocates, founded in the reign of Charles II., was given the copyright privilege of the Copyright Act of Queen Anne, and it became one of the great public libraries of the United Kingdom. It was open to the public, but the members of the faculty, whose property it was, bore the whole responsibility for maintenance and upkeep. Even before the World War, this burden was too heavy for a small body of professional men, and the subsequent rise in prices rendered it impossible to maintain the library on the old scale and to continue the facilities given to the public. In 1922 the faculty offered to transfer the library, with the exception of the collection of legal books, to the nation, but the Government replied that in the existing state of the national finances it could not undertake the responsibility of maintenance, and it was not until June 1923, when Sir Alexander Grant, Bt., intimated a gift of £100,000, the sum for which the Treasury had stipulated, that the project became feasible. Negotiations with the Government were at once resumed, but arrangements for the transfer, and two changes of Government, delayed the passage of a bill which became in 1925 the National Library of Scotland Act. The great library is now administered by a body of trustees, some of whom are *ex officio*, and others are appointed by the Crown or by administrative and educational authorities, or are co-opted by the trustees. The books continue meanwhile to be housed in the premises belonging to the Faculty of Advocates, which has included in its gift such portions of the buildings as are not needed for its own administrative purposes.

BIBLIOGRAPHY.—*General Histories.* The best general histories of Scotland are those of Patrick Fraser-Tytler (1841–43), John Hill Burton (1867–70), Peter Hume Brown (1899–1909) and Andrew Lang (1900–07). Tytler's History, which ends in 1603, is based on thorough research in mss., but many documents now available, such as the reports of diplomatic agents were not accessible when he wrote. Hill Burton's ends in 1746 and is of unequal merit, being best in points of development of law, but his anti-Celticism, and scepticism with regard to archaeology make his work inadequate in the earlier parts. Hume Brown's original work ended with the Disruption of 1843, but

an illustrated edition (1911) brings the story down to the date of publication. It is a judicious narrative, critical and cautious in its use of evidence and brings out the factors which affected the political development of the country. Lang, who carried his narrative down to 1746, was deeply interested in controversial issues and in secret history, and he described his book as a "study of spies and traitors." *See* also Sir Walter Scott's *Tales of a Grandfather,* which, in spite of its date, remains an excellent introduction to Scottish history.

Special Periods. For the period up to the death of Alexander III., 1286, W. F. Skene, *Celtic Scotland* (1876–80) and *Highlanders of Scotland* (ed. A. Macbain, 1902) are still standard works, though Skene's conclusions have been subjected to considerable criticism; *e.g.,* in Rhys's *Celtic Britain* (1884). E. W. Robertson, *Scotland under her Early Kings* (1862), is invaluable for the later portion of the period and especially for the discussion of the relations of the Crowns of Scotland and England. For the War of Independence, Joseph Bain, *The Edwards in Scotland* (1901), and E. M. Barron, *Scottish War of Independence* (1914), should be read; the last mentioned supplies information which has not yet been incorporated in the general histories about the attitude of the Highlands to the war. John Knox, *History of the Reformation,* should be studied in conjunction with Lang's *John Knox and the Reformation* (1905) and with Hay Fleming, *Reformation in Scotland* (1910). W. L. Mathieson, *Politics and Religion: a Study in Scottish History* (1902), treats the period 1550–1695 from a modern and moderate standpoint, covering the whole Covenanting period. The Union is discussed in Prof. James MacKinnon's *Union of England and Scotland* (2nd ed. 1907); Hume Brown, *Union of England and Scotland* (1914); Dicey and Rait, *Thoughts on the Scottish Union* (1920); and W. L. Mathieson, *Scotland and the Union* (1905), which covers the period 1695–1747. For the 18th century *see* W. L. Mathieson, *Awakening of Scotland, 1747–97* (1910), and Sir Henry Craik, *Century of Scottish History* (1901), which gives an acute analysis of the factors in the making of the nation from before the Rising of 1745 to the Education Act of 1872 and includes the Disruption controversy.

Special Topics. Constitutional History: Cosmo Innes, *Scotch Legal Antiquities* (1872) and *Scotland in the Middle Ages* (1860), R. S. Rait, *Parliaments of Scotland* (1924); James MacKinnon, *Constitutional History of Scotland* (1924). The best history of the Mediaeval Church is A. McEwan, *History of the Church in Scotland* (1912); for the organization of the Mediaeval Church *see* Bishop Dowden *Mediaeval Church in Scotland* (1910). For later church history, John Cunningham, *Church History of Scotland* (2nd ed. 1882), has still no rival. Social history: Cosmo Innes, *Sketches of Early Scotch History and Social Progress* (1861); John Mackintosh, *History of Civilization in Scotland* (1877–88); Hume Brown, *Scotland in the Time of Queen Mary* (1904); Henry Grey Graham, *Social Life in the 18th Century* (1899), and the topic is well illustrated in Robert Chambers, *Domestic Annals of Scotland* (1858–61). *See* also W. M. Mackenzie, *The Castle in Scotland* (1927). For the Highlands, Dr. Gregory's *History of the Highlands* (1881) is excellent, but it ceases at 1603.

Biographies. Only a few of the more important biographies can be mentioned—Sir Herbert Maxwell, *Robert Bruce* (1897); Hume Brown, *George Buchanan* (1890) and *John Knox* (1895); Hay Fleming, *Mary Queen of Scots* (1897); Thomas McCrie, *John Knox* (1811) and *Andrew Melville* (1819); C. S. Terry, *Claverhouse* (1905); W. C. MacKenzie, *Lauderdale* (1923); Andrew Lang, *Sir George MacKenzie* (1909) and *Prince Charles Edward* (1900).

State Papers and Society Publications. The most important additions to current knowledge are being made through the documents in course of publication in a large variety of series by H.M. Stationery Office (including Registers of the Privy Council, the Great Seal and the Privy Seal, the Exchequer Rolls and the Accounts of the Lord High Treasurer) and through the publications of the learned societies, such as the Scottish History Society and the Scottish Text Society, which are continuing the work accomplished a century ago by the Bannatyne, Maitland, Abbotsford and other clubs. A large number of important articles will be found in the *Scottish Historical Review* (1904–28). Some of the earlier series of State papers require to be checked by the original mss. (R. S. R.)

SCOTLAND, CHURCH OF. The purpose of this article is to trace the growth of the Scottish "Kirk" as a whole, defining the views on which it was based and the organization in which they took form. The controversies within the Church of Scotland have not arisen out of matters of faith but out of practical questions of church government and of the relation of church and state. Holding a church theory to which the rulers of the country were for a century strongly opposed, Scotland became the leading exponent of Presbyterianism (*q.v.*); and this note has been the dominant one in her religious history even in recent times.

Scottish Reformation.—The Scottish Reformation came out of a covenant in which the barons, inspired by John Knox, then abroad, bound themselves in 1557 to oppose the Roman Catholic religion and to promote the cause of the Reformation. When parliament, on the 24th of August 1560, passed the acts abolishing the papal jurisdiction and the mass in Scotland, it was able, as Knox had been preparing for this crisis, to sanction a new confession of faith for the Reformed church. Other documents of the new system were quickly forthcoming. The *First Book of Discipline* set forth the whole of the proposed religious and educational constitution, and this book speaks of "the order of Geneva which is now in use in some of our churches." This order, afterwards with some modifications known as John Knox's Liturgy, and used in the church down to the reign of Charles I., is a complete directory of worship, with forms of all the services to be held in the church. The type of religion found in these documents is that of Geneva, the unit being the self-governing congregation, and the great aim of the system the pure preaching of the Word; but the First Book of Discipline does not set forth any complete scheme of church government. Its arrangements are in part provisional. In addition to the minister, who is its most definite figure and proved to be the most permanent, it recognizes the superintendent, the lay elder and the reader. The superintendent was a parish minister whose added function was to plant churches, and place ministers, elders and deacons where required. Whether the superintendents were meant to be permanent in the church is not clear. The lay elder was very much what he is still. The reader was to conduct service when no minister was available, reading the Scriptures and the Common Prayer. A noble scheme of education was sketched for the whole country, but neither this nor the provision made for ministers' stipends was carried out, the revenues of the old church, from which the expenses of both were to be paid, being in the hands of the barons.

The system naturally took time to get into working order. The old clergy, bishops, abbots and priests were still on the ground, and were slow to take service in the new church. In 1574 there were 289 ministers and 715 readers. As the ranks of the clergy slowly filled, questions arose which the Reformation had not settled, and it was natural that the old system with which the country was familiar should creep in again. Presbytery was never much in favour with the crown; and when the crown, so weak at the Reformation, gained strength, encroachments were made on the popular character of the kirk, while the barons also had obvious reasons for not wishing the kirk to be too strong. The first parliament of the Regent Moray (1567), while confirming the establishment of the Reformed church as the only true church of Christ, settling the Protestant succession, and doing something to secure the right of stipend to ministers, reintroduced lay patronage, the superintendent being charged to induct the patron's nominee—an infringement of the reformed system against which the church never ceased to protest. Andrew Melville (*q.v.*) came to Scotland at this time, and became the leader of the church in place of Knox, who died in 1572. He brought with him from Geneva, where he had been the colleague of Beza, a fervent hatred of ecclesiastical tyranny and a clear grasp of the Presbyterian church system. The Scottish church, hitherto without a definite constitution, soon espoused under his able leadership a logical and thorough Presbyterianism, which was expressed in the *Second Book of Discipline,* adopted by the assembly in 1577, and was never afterwards set aside by the church when acting freely. It recognizes four kinds of office in the church, and no one can lawfully be placed in any of them except by being called to it by the members. Pastor, bishop and minister are all titles of the same office, that of those who preach the word and administer the sacraments, each to a particular congregation. The doctor is a teacher in school or university; he is an elder and assists in the work of government. Elders are rulers; their function also is spiritual, though practical and disciplinary. The fourth office is that of the deacons, who have to do with matters of property and are not members of church courts. Kirk-sessions and presbyteries are not named, but the principles are clearly laid down on which these institutions are to rest.

Presbyterian Principle.—By committing herself to this system the Church of Scotland established between herself and the

Church of England a division which became more and more apparent and was the cause of much of her subsequent sufferings. It is no doubt strange that she should have endured so much not for any great Christian principle, but for a question of church government. On the other hand, Presbyterianism stood in Scottish history for freedom, and for the rights of the middle and lower classes against the crown and the aristocracy; and it might not have been held with such tenacity or proved so incapable of compromise but for the opposition and persecution of the three Stuart kings. The history of the Scottish church for a century after the date of the Book of Discipline is that of a religious struggle between the people and the crown.

For some years after its inception Presbyterianism carried all before it. The presbyteries came quickly into existence; that of Edinburgh dates from 1580. In that year it was found that there were 924 parishes in Scotland, but not nearly all supplied with ministers; it was proposed that there should be 50 presbyteries and 400 ministers. A great part of the country, especially in the north and west, had not yet been reached by the Reformation. At this time began the long series of attempts made by James VI. in the direction of curbing Presbyterian liberty and of the restoration of Episcopacy. For a few years his attitude was different. A Roman Catholic rising threw James into the arms of the kirk; in 1592 the Second Book of Discipline was legalized and Presbytery set up. The church was at the time very powerful, the people generally sympathizing with her system, and her assemblies being attended by many of the nobles and the foremost men. Discipline was strict; the temper of the church was in accordance with the Old rather than the New Testament. On his accession to the throne of England in 1603 James entered on a new set of attempts to assimilate the Scottish church to that of England. In 1609 two courts of high commission were set up by the royal authority with plenary powers to enforce conformity to the new arrangements. In 1612 the act of 1592 which established Presbytery was rescinded, and Episcopacy became the legal church system of Scotland.

National Covenant.—In all this it was the position and rights of the clergy that were assailed. The people had been less interfered with; the change of church government involved no change in the conduct of worship. But the articles of Perth, passed by a packed assembly in 1618, foreshadowed what was soon to be the policy of the crown. During the first years of his reign Charles was occupied in other directions; but when he came to Scotland in 1633 to be crowned, Laud came with him, and though like his father he showed himself kind to the clergy in matters of stipend, and adopted measures which caused many schools to be built, he also showed that in the matter of worship the policy of forcing Scotland into uniformity with England was to be carried through with a high hand. A book of canons and constitutions of the church which appeared in 1636, instead of being a digest of acts of assembly, was English in its ideas, dealt with matters of church furniture, exalted the bishops and ignored the kirk-session and elders. The liturgy was ordered to be used, which had not yet appeared, but which proved to be a version, with somewhat higher doctrine, of the Anglican Common Prayer. The introduction of this service book in St. Giles's Church, Edinburgh, on the 16th of July 1637, occasioned the tumult of which Jenny Geddes will always figure as the heroine. The sentiment was echoed throughout Scotland. Petitions against the service book and the book of canons poured in from every quarter; the committee formed to forward the petition rapidly became a powerful body at the head of a national movement, the action of the crown was temporizing, and on the 28th of February the National Covenant was signed in the famous scene in Greyfriars church and churchyard. This document recited the covenant, signed by King James and his household in 1580, to uphold Presbyterianism and to defend the state against Romanism, and then declared a new covenant of nobles, barons, gentlemen, burgesses, ministers and commons to continue in the reformed religion, to defend it and resist all contrary errors and corruptions. The Covenant was no doubt an act of revolt against legal authority, and can only be justified on the ground that the crown had for many years acted oppressively and illegally in its attempt to coerce Scotland into a religious system alien to the country, and that the subjects were entitled to free themselves from tyranny. The crown was unable either to check the popular movement or to come to any compromise with it, and the Glasgow assembly of 1638, the first free assembly that had met for thirty years, proceeded to make the church what the Covenant required, and effected the "second Scottish reformation." The assembly contained many influential laymen and was carried on the crest of a great national movement. The Covenant was accepted by parliament in 1639.

The succeeding decennium is the culminating period of Scottish Presbyterianism, when, having successfully resisted the crown, it not only was supreme in Scotland but exercised a decisive influence over England. The causes which brought about this state of affairs are to be sought to a large extent in the civil history of England. The English parliament sought the alliance of the assembly, while the Independents, though in the event Presbytery was as little to their liking as Episcopacy, joined in the wish to get rid of the episcopal system. In its period of triumph the Presbyterianism of Scotland displayed its character. After the injustice and persecution it had suffered it could scarcely prove moderate or tolerant; it showed a vehement determination to carry out the truth it had vindicated with such enthusiasm, to the full extent and wherever possible. The Covenant, at first a standard of freedom, was immediately converted into a test and made the instrument of oppression and persecution. All policy was to be determined by the Covenant; the king and every official was to be obliged to take it. The mind of the nation being so preoccupied with the Covenant, it naturally followed that those who carried their fanaticism farthest were ready to denounce and to unchurch those who showed any inclination to moderation and political sanity, and that the beginnings of schism soon appeared in the ranks of the Covenanters.

In 1643, when the full legal establishment of Presbytery had just been consummated, the General Assembly, asked by the English parliament to arrange a league to be signed in both countries for the furtherance of reformed religion, agreed, but asked that the league should be a religious one. The result was the Solemn League and Covenant. It did not mention Presbyterianism; but the Assembly had refused to hear of any recognition of independency; if religion were thoroughly reformed, they considered the result must be Presbyterianism in England as in Scotland. In the Westminster Standards also, which were the fruit of the Scottish desire for a religious uniformity, Scotland did not obtain by any means all it desired in its church documents. The Scottish divines in the Westminster Assembly were only five in number, while the assembly contained effective parties of Erastians and Independents. The Confession of Faith contains no approval of any system of church government, and when she adopted it in 1647 the kirk gave up her old confession in which the principles at least of true church order are laid down. In accepting in 1645 the Westminster Directory of Public Worship she tacitly gave up her own liturgy which had been in use till recently, and committed herself to a bald and uninviting order of worship, in which no forms of prayer were allowed to be used.

Struggle Against Episcopacy.—If the mismanagement of Scottish religious affairs under James and Charles I. is a melancholy story, what took place under Charles II. is infinitely sadder. From the first Charles showed himself determined to force Episcopalianism on Scotland, and not too scrupulous in the choice of methods for securing his ends. The attempt was nearly successful. In the greater part of the country little change took place in the religious services. The service book was not read nor kneeling at communion required, and it made no immediate difference to the people that the clergy should be under bishops. The inferior church courts still sat, though not the assembly. At the Restoration it was a question whether the bulk of the population was in favour of Presbytery or of Episcopacy; but the matter was handled in such a way in the west of Scotland that an extreme Covenanting spirit arose, nourished on intolerable grievances,

and the nation as a whole decided against the system which had been promoted by such means.

The Rescissory Act of 1661 swept away the legislation of the preceding twenty years, and so disposed of the Presbyterian polity of the church. Episcopacy was restored by a letter from the king on the 5th of September 1661 (*see* Scotland, Episcopal Church of). An act requiring all ministers appointed during the period when patronage was abolished to get presentation from their patrons and institution from their bishops was applied in the west of Scotland in such a way that 300 ministers left their manses. Their places were filled with less competent men whom the people did not wish to hear, and so conventicles began to be held. The attempts to suppress these, the harsh measures taken against those who attended them or connived at them, or refused to give information against them, the military violence and the judicial severities, the confiscations, imprisonments, tortures, expatriations, all make up a dreadful narrative. Indulgences were tried, and were successful in bringing back about 100 ministers to their parishes and introducing a new cause of division among the clergy. On the other hand, the Covenanting spirit rose higher and higher among the persecuted till the armed risings took place and the formal rebellion of a handful of desperate men against the ruler of three kingdoms.

When William landed in England in 1688, the scene changed in Scotland. The soldiery was withdrawn from the west, and the people at once showed their feelings by the "rabbling" or ejection of the curates who occupied the manses of the ousted ministers, in which, however, no lives were lost. William would have decided for Episcopacy in Scotland, as the great body of the nobles and gentry adhered to it, but only on condition that the Episcopalians agreed to support him and that they had the people with them. Neither of these conditions was fulfilled. On the 22nd of July 1689 the Convention which declared the throne vacant and called William and Mary to fill it, declared in its Claim of Right that prelacy and the superiority of any office in the church above ministers had been a great and insupportable grievance to Scotland. Effect was given to this; and in April 1690 the act was passed on which the establishment of the Church of Scotland rests, the Westminster Confession being recognized, the laws in favour of Episcopacy repealed, though the Rescissory Act remained on the statute book, and the assembly appointed to meet. Three years later the formula of subscription, to be signed by all ministers, was fixed.

From this time forward the church, while jealously asserting her spiritual independence, was on the side of the crown against the Jacobites, and became more and more an orderly and useful ally of the state. The difficulties which threatened to arise about the union were skilfully avoided; the Act of Security provided that the Confession of Faith and the Presbyterian government should "continue without any alteration to the people of this land in all succeeding ages," and the first oath taken by Queen Anne at her accession was to preserve it. The Act of Toleration of 1712 allowed Episcopalian dissenters to use the English liturgy. This had not hitherto been done, and the claim of the Episcopalians for this liberty had been the occasion of a bitter controversy. The same parliament restored lay patronage in Scotland, an act against which the church always protested and which was the origin of great troubles.

Patronage Difficulties.—Presbytery, being loyal to the house of Hanover, while Episcopacy was Jacobite, was now in enjoyment of the royal favour and was treated as a firm ally of the government. But while the church as a whole was more peaceful, more courtly, more inclined to the friendship of the world than at any former time, it contained two well-marked parties. The Moderate party, which maintained its ascendancy till the beginning of the 19th century, sought to make the working of the church in its different parts as orderly and regular as possible, to make the assembly supreme and to enforce on presbyteries respect for its decisions. The Popular party, regarding the church less from the side of the government, had less sympathy with the progressive movements of the age, and desired greater strictness in discipline. The main subject of dispute arose at first from the exercise of patronage. Presbyteries in various parts of the country were still disposed to disregard the presentations of lay patrons, and to settle the men desired by the people; but legal decisions had shown that if they acted in this way their nominee, while legally minister of the parish, could not claim the stipend. To the risk of such sacrifices the church, led by the Moderate party, refused to expose herself. By the new policy inaugurated by Dr. William Robertson (1721–1793), the assembly compelled presbyteries to give effect to presentations, and in a long series of disputed settlements the "call," though still held essential to a settlement, was less and less regarded, until it was declared that it was not necessary, and that the church courts were bound to induct any qualified presentee. The substitution of the word "concurrence" for "call" about 1764 indicates the subsidiary and ornamental light in which the assent of the parishioners was now to be regarded. It was in the power of the church to give more weight than she did to the feelings of the people; but her working of the patronage system drove large numbers from the Establishment. A melancholy catalogue of forced settlements marks the annals of the church from 1749 to 1780, and wherever an unpopular presentee was settled the people quietly left the Establishment and erected a meeting-house.

Growth of Dissent.—In 1763 there was a great debate in the Assembly on the progress of schism, in which the Popular party laid the whole blame at the door of the Moderates, while the Moderates rejoined that patronage and Moderatism had made the church the dignified and powerful institution she had come to be. Nor was a conciliatory attitude taken up towards the seceders. The ministers of the Relief (*see* United Presbyterian Church) desired to remain connected with the Establishment, but were not suffered to do so. Those ministers who resigned their parishes to accept calls to Relief congregations, in places where forced settlements had taken place, and who might have been and claimed to be recognized as still ministers of the church, were deposed and forbidden to look for any ministerial communion with the clergy of the Establishment. The growth of dissent steadily continued and excited alarm from time to time; and it may be questioned whether the peace of the church was not purchased at too high a price. The Moderate period is justly regarded as in some respects the most brilliant in the history of the church. Her clergy included many distinguished Scotsmen, among them Thomas Reid, George Campbell, Adam Ferguson, John Home, Hugh Blair, William Robertson and John Erskine. The labours of these men were not mainly in theology; in religion the age was one not of advance but of rest; they gained for the church a great and widespread respect and influence.

Revival.—With the close of the 18th century a great change passed over the spirit of the church. The new activity which sprang up everywhere after the French Revolution produced in Scotland a revival of Evangelicalism. Moderatism had cultivated the ministers too fast for the people, and the church had become to a large extent more of a dignified ruler than a spiritual mother. About this time the brothers Robert and James Haldane devoted themselves to the work of promoting Evangelical Christianity, James making missionary journeys throughout Scotland and founding Sunday schools; and in 1798 the eccentric preacher Rowland Hill visited Scotland at their request. In the journals of these evangelists dark pictures are drawn of the religious state of the country, though their censorious tone detracts greatly from their value; but there is no doubt that the efforts of the Haldanes brought about or coincided with a quickening of the religious spirit of Scotland. The assembly of 1799 passed an act forbidding the admission to the pulpits of laymen or of ministers of other churches, and issued a manifesto on Sunday schools. These acts helped greatly to discredit the Moderate party, of whose spirit they were the outcome. In 1810 the *Christian Instructor* began to appear under the editorship of Dr. Andrew Thomson, a churchman of vigorous intellect and noble character. It was an ably written review, in which the theology of the Haldanes asserted itself in a somewhat dogmatic and confident tone against all unsoundness and Moderatism, clearly proclaiming that the former things had passed away. The question of pluralities began to be

agitated in 1813, and gave rise to a long struggle, in which Dr. Thomas Chalmers (*q.v.*) took a notable part, and which terminated in the regulation that a university chair or principalship should not be held along with a parish which was not close to the university seat.

The growth of Evangelical sentiment in the church, along with the example of the great missionary societies founded in the end of the 18th and the beginning of the 19th century, led to the institution of the various missionary schemes, and their history forms the chief part of the history of the church for a number of years. The education scheme, having for its object the planting of schools in destitute Highland districts, came into existence in 1824. The foreign mission committee was formed in 1825, at the instance of Dr. John Inglis (1763–1834), a leader of the Moderate party; and Dr. Alexander Duff (*q.v.*) went to India in 1829 as the first missionary of the Church of Scotland. The church extension committee was first appointed in 1828, and in 1834 it was made permanent. It was originally formed to collect information regarding the spiritual wants of the country, and to apply to the government to build the churches found to be necessary. As the population of Scotland had doubled since the Reformation, and its distribution had been completely altered in many counties, while the number of parish churches remained unchanged, and meeting-houses had only been erected where seceding congregations required them, the need for new churches was very great. The application to government for aid, however, proved the occasion of a "Voluntary controversy," which raged with great fierceness for many years and has never completely subsided. The union of the Burgher and the Anti-burgher bodies in 1820 in the United Secession (*see* UNITED PRESBYTERIAN CHURCH) added to the influence of the voluntary principle in the country, while the political excitement of the period disposed men's minds to such discussions. The government built forty-two churches in the Highlands, providing them with a slender endowment; and these are still known as parliamentary churches. Under Thomas Chalmers, however, the church extension committee struck out a new line of action. The great philanthropist had come to see that the church could only reach the masses of the people effectively by greatly increasing the number of her places of worship and abolishing or minimizing seat-rents in the poorer districts. In his powerful defence of establishments against the voluntaries in both Scotland and England, in which his ablest assistants were those who afterwards became, along with him, the leaders of the Free Church, he pleaded that an established church to be effective must divide the country territorially into a large number of small parishes, so that every corner of the land and every person, of whatever class, shall actually enjoy the benefits of the parochial machinery. This "territorial principle" the church has steadily kept in view ever since. With the view of realizing this idea he appealed to the church to provide funds to build a large number of new churches, and personally carried his appeal throughout the country. By 1840 over 200 new churches had been built.

The zealous orthodoxy of the church found at this period several occasions to assert itself. John M'Leod Campbell (*q.v.*), minister of Row, was deposed by the assembly of 1830 for teaching that assurance is of the essence of faith and that Christ died for all men. He has since been recognized as one of the profoundest Scottish theologians of the 19th century, although his deposition was never removed. The same assembly condemned the doctrine put forth by Edward Irving (*q.v.*), that Christ took upon Him the sinful nature of man and was not impeccable, and Irving was deposed five years later by the Presbytery of Annan, when the outburst of supposed miraculous gifts in his church in London had rendered him still more obnoxious to the strict censures of the period (*see* CATHOLIC APOSTOLIC CHURCH).

The Disruption—and After.—The influence of dissent also acted along with the rapidly rising religious fervour of the age in quickening in the church that sense of a divine mission, and of the right and power to carry out that mission without obstruction from any worldly authority, which belongs to the essential consciousness of the Christian church. An agitation against patronage, the ancient root of evil, and the formation of an anti-patronage society, helped in that direction. For the Ten Years' Conflict, which began in 1833 with the passing by the Assembly of the Veto Act, *see* the article FREE CHURCH OF SCOTLAND; it is not necessary to dwell further in this place on the consequences of those acts. The Assembly of 1843, from which the exodus took place, proceeded to undo the acts of the church during the preceding nine years. The Veto was not repealed but ignored, as having never had the force of law. The Assembly addressed a pastoral letter to the people of the country, in which, while declining to "admit that the course taken by the seceders was justified by irresistible necessity," they counselled peace and goodwill towards them, and called for the loyal support of the remaining members of the church. Two acts at once passed through the legislature in answer to the claims put forward by the church. The Scottish Benefices Act of Lord Aberdeen, 1843, gave the people power to state objections personal to a presentee, and bearing on his fitness for the particular charge to which he was presented, and also authorized the presbytery in dealing with the objections to look to the number and character of the objectors.

Development Since 1843.—The Disruption left the Church of Scotland in a sadly maimed condition. Of 1203 ministers 451 left her, and among these were many of her foremost men. A third of her membership is computed to have gone with them. In Edinburgh many of her churches were nearly empty. The Gaelic-speaking population of the northern counties completely deserted her. All her missionaries left her but one. She had no gale of popular enthusiasm to carry her forward, representing as she did not a newly arisen principle but opposition to a principle which she maintained to be dangerous and exaggerated. For many years she had much obloquy to endure. But she at once set herself to the task of filling up vacancies and recruiting the missionary staff. A lay association was formed, which raised large sums of money for the missionary schemes, so that their income was not allowed seriously to decline. The good works of the church, indeed, were in a few years not only continued but extended. All hope being lost that parliament would endow the new churches built by the church extension scheme of Dr. Chalmers, it was felt that this also must be the work of voluntary liberality.

Agitation on the subject of patronage went on in the Assembly from 1857 to 1869, when by a large majority patronage as restored by the Act of Queen Anne was condemned, and a petition sent to parliament for its removal. The request was granted, and the right of electing parish ministers was conferred by the Patronage Act 1874 on the congregation; thus a grievance of old standing, from which all the ecclesiastical troubles of a century and a half had sprung, was removed and the church placed on a thoroughly democratic basis. This act, combined with various efforts made within the church for her improvement, secured for the Scottish Establishment a large measure of popular favour, and in the last half of the 19th century she grew rapidly both in numbers and in influence. This revival was largely due on the one hand to the improvement of her worship which began with the efforts of Dr. Robert Lee (1804–1868), minister of Old Greyfriars, Edinburgh, and professor of Biblical criticism in Edinburgh university. By introducing into his church a printed book of prayers and also an organ, Dr. Lee stirred up vehement controversies in the church courts, which resulted in the recognition of the liberty of congregations to improve their worship. The Church Service Society, having for its object the study of ancient and modern liturgies, with a view to the preparation of forms of prayer for public worship, was founded in 1865; it has published eight editions of its "Book of Common Order," which, though at first regarded with suspicion, has been largely used by the clergy. Church music has been cultivated and improved in a marked degree; and hymns have been introduced to supplement the psalms and paraphrases; in 1898 a committee appointed by the Church of Scotland, the Free Church, the United Presbyterian Church and the Presbyterian Church in Ireland issued *The Church Hymnary*, which was authorized for use in all these churches alike, and after 30 years a new hymnary is being compiled.

The "Committee on Christian Life and Work," was appointed in 1869 with the aim of exercising some supervision of the work of

the church throughout the country, stimulating evangelistic efforts and organizing the labours of lay agents. This committee publishes a magazine of "Life and Work," which has a circulation of over 100,000, and has organized young men's gilds in connection with congregations and revived the ancient order of deaconesses. It was to reinforce this element of the church's activity, as well as to strengthen her generally, that James Baird (1802–1876) in 1873 made the munificent gift of £500,000. This fund is administered by a trust which is not under the control of the church, and the revenue is used mainly in aid of church building and endowment throughout the country.

Subscription and Re-union.—The church has greatly increased of late years in width of view and liberality of sentiment, and shelters various tendencies of thought; and for this and other reasons the question of subscription has been more or less before the church for many years. The formula adopted by the assembly of 1711 had still to be signed by ministers, and was felt to be much too strict. After debates extending over many years, the assembly of 1889 fell back on the words of the act of parliament 1693, passed to enable the Episcopalian clergy to join the establishment, in which the candidate declared the Confession of Faith to be the confession of his faith, owned the doctrine therein contained to be the true doctrine and promised faithfully to adhere to it. This was accompanied by a Declaratory Act in which the church expressed its desire to enlarge rather than curtail the liberty hitherto enjoyed. Ten years later the assembly was again debating the question of subscription. A committee appointed in 1899 to inquire into the powers of the church in the matter reported that the power of the church was merely administrative—it was in her power as cases arose to prosecute or to refrain from prosecuting, but that she had no power to modify the confession in any way. Here the matter might have remained, but that the approach to parliament of the United and the Free Churches after the decision of the House of Lords in 1904 (*see* FREE CHURCH and UNITED FREE CHURCH) offered an opportunity for asking parliament to remove a grievance the church herself had no power to deal with. The Scottish Churches Bill of 1905 left it to the Church of Scotland to frame a new formula for her ministers and professors, an undertaking to which she is seriously addressing herself.

Since 1909—when the quater-centenary of the birth of Calvin brought the Church of Scotland and United Free Church Assemblies together in a memorial service in St. Giles's, and a joint-committee on union was appointed—the two bodies have been moving towards reunion. The negotiations, interrupted by the War, have been resumed, and the main causes of keeping the Churches apart have been removed.

The leaders of the Church of Scotland have already twice gone to Parliament in order to secure Acts which might remove the scruples of the other Church; the first Act (in 1921) ratified a Constitution drawn up by the Church declaring her spiritual freedom, with Nine Articles outlining an acceptable doctrinal basis; the second (in 1925) ratified a financial arrangement between the Church and the heritors, relating to the teinds. Finally the General Assemblies of the Church of Scotland and the United Free Church, at their meetings held in Edinburgh in May, 1929, both resolved on an incorporating union of the two Churches. The incorporating resolution was passed by the Assembly of the Church of Scotland with practical unanimity and by the Assembly of the United Free Church with an overwhelming majority. The union was consummated at a meeting of the Assemblies held on October 2, 1929, at the Cathedral of St. Giles, according to the plan formulated in May.

BIBLIOGRAPHY.—For the earlier history of the kirk the outstanding authorities are the histories of Knox, Calderwood, Baillie's *Letters*, and Wodrow's *History:* Knox's liturgy has been edited by Dr. Sprott, and on the Westminster Standards the reader may consult Dr. Mitchell's *Minutes of the Westminster Assembly*, and Baird lectures on the same subject. Modern histories of the church have been written by Cook, Hetherington and Principal Cunningham; Dr. Story's *Church of Scotland* in 5 vols. contains information on every side of the subject. Among books professedly dealing with the Free Church question, the most valuable are Sydow's *Die Schottische Kirchenfrage* (Potsdam, 1845), and *The Scottish Church Question* (London, 1845); Buchanan's *Ten Years' Conflict* (1849); Hanna's *Life of Chalmers* (1852); and Taylor Innes on *The Law of Creeds in Scotland* (1867). *See* also Cockburn, *Memorials of His Time* (Continuation, 1874); Walker, *Dr. Robert Buchanan: an Ecclesiastical Biography* (1877); *Annals of the Disruption* (published by authority of a committee of the Free Church (1876–77). On the United Presbyterian Church *see* McKerrow, *History of the United Secession Church* (1841); Struthers, *History of the Relief Church* (1843); McKelvie, *Annals and Statistics of the United Presbyterian Church* (1873); and on re-union, A. Martin, *Church Union in Scotland* (1910).

(A. Ms.; X.)

SCOTLAND, EPISCOPAL CHURCH OF, a Scottish Episcopal church in communion with, but historically distinct from, the Church of England, and composed of seven dioceses: Aberdeen and Orkney; Argyll and the Isles; Brechin; Edinburgh, Glasgow and Galloway; Moray, Ross and Caithness; and St. Andrews, Dunkeld and Dunblane. All, except Edinburgh, founded by Charles I., are pre-Reformation sees. The bishops constitute the episcopal synod, the supreme court of appeal, whose president, elected by the members from among themselves, has the style, not the functions, of a metropolitan, being called primus. The legislature is the provincial synod, consisting of the bishops, at whose discretion it is summoned, and a lower chamber of presbyters. The canons have the authority of this synod. The representative church council, including laymen, administers finance. Each diocese has its synod of the clergy. Its dean is appointed by the bishop, and, on the voidance of the see, summons the clerical and lay electors, at the instance of the primus, to choose a bishop, who is presented to the episcopal synod for confirmation and to the primus for consecration. There are cathedrals at Perth, Inverness, Edinburgh and Cumbrae; the sees of Aberdeen, Brechin and Glasgow have no cathedrals. The Theological College was founded in 1810, incorporated with Trinity College, Glenalmond, in 1848, and re-established at Edinburgh in 1876.

The bishops of the Episcopal Church are direct successors of the prelates consecrated to Scottish sees at the Restoration. After the Revolution, the Comprehension Act of 1690 allowed episcopalian incumbents, on taking the Oath of Allegiance, to retain their benefices, though excluding them from any share in the government without a further declaration of presbyterian principles. The extruded bishops were slow to organize the episcopalian remnant under a jurisdiction independent of the state, regarding the then arrangements as provisional, and looking forward to a reconstituted national kirk under a "legitimate" sovereign. But at length the hopelessness of the Stuart cause and the growth of congregations outside the establishment forced the bishops to dissociate canonical jurisdiction from royal prerogative and to reconstitute for themselves a territorial episcopate. The act of Queen Anne (1712), which protects the "Episcopal Communion," marks its virtual incorporation as a distinct society. But matters were still complicated by a considerable, though declining, number of episcopalian incumbents holding the parish churches. Moreover, the Jacobitism of some of the clergy provoked a state policy of repression in 1715 and 1745, and fostered the growth of new Hanoverian congregations, served by clergy episcopally ordained but amenable to no bishop, who qualified themselves under the act of 1712. These causes reduced the Episcopalians, who included at the Revolution a large section of the people, to what is now, save in a few corners of the west and north-east of Scotland, a small minority; but the chief bar to progress had been removed by the official recognition of George III. on the death of Charles Edward in 1788. The latest statistics show 421 churches and mission stations, 321 clergy, and 60,495 communicants.

On the history, *see* Carstares, *State Papers;* Keith, *Historical Catalogue of the Scottish Bishops* (Russel's edition, 1824); Lawson, *History of the Scottish Episcopal Church from the Revolution to the Present Time* (1843); Stephen, *History of the Church of Scotland from the Reformation to the Present Time* (4 vols., 1843); Lathbury, *History of the Nonjurors* (1845); Grub, *Ecclesiastical History of Scotland* (4 vols., 1861); Dowden, *Annotated Scottish Communion Office* (1884).

SCOTS GREYS, THE ROYAL (2nd Dragoons). This famous corps was raised in Scotland in 1678 and derives its title from the colour of its original facings—stone grey. They have also always been mounted on grey horses for a great number

of years. As the Scots Dragoons they served under William III. in Flanders. In 1702 as the Grey Dragoons they served in the Low Countries. The regiment was at the battle of Blenheim, captured a standard of the French *Régiment du Roi* at Ramillies, and was also with the victorious army at Oudenarde and Malplaquet. In 1736 it bore the title of Royal North British Dragoons which it retained until March 1877, when it became the 2nd Dragoons (Royal Scots Greys). At Waterloo Napoleon referred to the Greys as *ces terribles chevaux gris* owing to their fine fighting qualities. Here they captured an "eagle" (standard) of the 45th French Line Regiment. Their long roll of battle honours also shows service in the Crimean War, South Africa 1899–1902, and the World War.

SCOTS LAW. At the union of the parliaments of England and Scotland, in 1707, the legal systems of the two countries were as disparate as was reasonably possible in two civilizations approximately equal. Scotland, mainly in the preceding century, had adopted Roman law, as developed, and in some respects altered, by the jurists of Holland and France, as her main guide; English lawyers had forgotten, or refused to acknowledge, the debt owed to Rome both by common law and equity. The law of Scotland, again, had recently been set forth in the *Institutions* of Lord Stair, a masterpiece of lucidity and orderly arrangement; in England the student or practitioner had little to guide him through a maze of precedents and forms of pleading beyond the difficult pages of Coke. And the Scots lawyer might have pointed, with pardonable pride, to the fact that in the court of session there was no separation of law and equity.

Historical Development.—The legal history of the succeeding centuries has been one of gradual assimilation, almost exclusively by the penetration of English rules into the law of Scotland.

The process of assimilation is by no means complete, but the apparent disparities are to a certain extent due to the difference in legal terminology. Thus there is little real distinction between the English "estoppel" and the Scotch "personal bar"; between "set-off" and "compensation"; between "merger" and *confusio;* between the doctrine of "advancement" and *collatio inter liberos.*

Causes of Assimilation.—Various causes have contributed to the gradual assimilation of English and Scots law. One main cause is that much of the existing law depends on statutes applicable to both countries. The House of Lords until 1876 almost exclusively English lawyers acting as the supreme court of appeal from Scotland, had a tendency to apply English law to Scotch appeals, and in some cases seems to have forgotten the distinction between its legislative and its judicial functions. Thus in *Jaffray* v. *Allan* (1790) 3 Paton 191, the House decided that the law of stoppage *in transitu* was applicable to Scotland, without any evidence that it had ever been suggested in Scots law.

The citation of English cases in Scotland, now of daily occurrence in practice, was very rare in the 18th century, and may be traced to Prof. Bell. Judicial remonstrances against the citation of English authorities, which the judges professed themselves unable to understand, persisted for the next 30 years. The reforms in English procedure, between 1830 and 1860, did much to make English authorities more intelligible in Scotland. Much remained to be done; the separation of law and equity was a constant stumbling-block; but at least the Scotch lawyer was no longer perplexed by the question of what John Doe and Richard Roe had to do with the case. The result has been, with some aid from legislation, that in many leading branches of commercial law, such as the law of bills of exchange and negotiable instruments, suretyship or cautionary, agency, insurance, carriers by land and sea, the difference between English and Scots laws is now negligible.

In attempting to indicate the main points on which English and Scots law still differ it would be hopeless to deal, within the limits of an article, with courts and procedure. In these respects any resemblance is accidental.

Land Tenure.—In the law of tenure of land there is no reason to suppose (though the early history of tenure in Scotland is very obscure) that any material difference existed in Norman times. But there are no statutes in Scotland equivalent to *Quia Emptores,* and while subinfeudation remained lawful and usual, the right of the vassal to alienate his feu without the superior's consent was not recognized by the legislature until 1747, although conveyancing expedients to enable him to do so had been devised at a much earlier date. The consequence has been that the rights of subject superiors has bulked much more largely in Scotland than in England. A series of statutes, culminating in the Feudal Casualties Act 1914, have abolished all prestations except feu-duty, and it may now be said that a "feu"—the normal tenure in Scotland—is equivalent to an English "freehold," subject, in cases where there is a feu-duty, to a perpetual rent charge. There is, however, a very important distinction in the system of registration of title, only partially and imperfectly developed in England. In Scotland, since the establishment of the registers of sasines, in 1617, all deeds relating to land may be recorded in that register, and it has for long been established that a purchaser, or a lender on heritable security, is entitled to trust to the registers, and is not affected by any conveyance or burden which is not there recorded.

Leases for any period exceeding 21 years, though not unknown, have never been common in Scotland. Recent legislation—the Crofters Act 1886 and the Small Landholders Act 1911—has established a system of leasehold in agricultural subjects not exceeding 50 acres, with security of tenure and the right to have the rent fixed judicially, and in this respect there is no English analogy. In other respects the law of leases is, in its main aspects, the same in England and Scotland. The Agricultural Holdings Acts (13 and 14 Geo. V. ch. 9 and 10) which respectively apply, differ only in minor details.

Husband and Wife.—In the law of husband and wife, the enfranchisement of married women has reached an approximately equal stage in each country. But the laws as to the constitution of marriage differ. While in England some form of official recognition or ceremony is necessary to the validity of a marriage, Scots law has preserved the rule that the mere interchange of consent (which may be verbal, and in certain cases is implied) is sufficient. Such marriages, where there is no religious ceremony, are termed irregular, but are fully binding in Scotland. By the Marriage (Scotland) Act 1856 no irregular marriage in Scotland is to be recognized by the English courts unless one or other of the parties has his or her usual residence in Scotland, or had resided there for the preceding 21 days. By the Matrimonial Causes Act 1923 the English law of divorce is so far assimilated to that of Scotland that adultery by either spouse is recognized as a sufficient ground of action. Scots law, however, recognizes, while English law does not, wilful desertion for four years by either spouse. In Scotland a decree of divorce dissolves the marriage at once; in England neither party is free to re-marry until, in any event, six months have expired.

Succession.—In the law of succession the Administration of Estates Act 1923, by establishing a general order in intestate succession in England, has created a fundamental difference. In Scotland the order of succession in heritable (real) and movable (personal) property remains separate. And Scots law has never admitted absolute freedom of bequest in cases where there is a surviving husband, wife or child. A widow has a legal right, known as *ius relictae,* to one half of her husband's movable property if there is no surviving child; if there is, to one third. A widower, by the Married Woman's Property Act 1881, has a similar right in the movable property of his wife (*ius relicti*). Children have a legal right to legitim in the movable estate of each parent, one half if there is no surviving spouse, one-third if there is. All rights may be excluded by ante-nuptial marriage contract; any particular claim by post-nuptial contract between husband and wife, or between parent and child. They cannot, however, be excluded or limited by will. In heritable property a widow has a legal right (tierce) to a liferent of one-third; a widower, under certain limitations, has a right of courtesy, which gives him a liferent of the whole of the wife's estate.

Wills.—In testate succession English authorities on the construction of wills are constantly cited in Scotland. Three points of difference may be noted. (1) Scots law recognizes the validity

of a will in the testator's handwriting (holograph), without witnesses. (2) It demands in every case subscription. There are legislative provisions (Conveyancing [Scotland] Act 1924) under which, when a testator cannot write, his will may be subscribed for him by a law agent, justice of the peace or parish minister. (3) The validity of a will is, in Scots law, in no case affected by the subsequent marriage of the testator.

Contracts.—In the general law of contract the most important distinction is that Scots law has never recognized the English doctrine of consideration. Perhaps a very important result is that Scots law admits the principle of *ius quaestium tertio, i.e.*, that C. may have a title to sue on a contract between A. and B. if made for his benefit; a right of action excluded in England by the principle that consideration must move from the promisee. In the contingency of contractual questions where the element of consideration does not enter, such as the effect of error, fraud, misrepresentation or illegality, the law, although not in all points identical, allows the citation of decisions in one country as authorities in the other. This cannot be said of the question as to the necessity of writing in the constitution or proof of an obligation; there, the law, depending on different statutes, seems completely dissimilar. And it has recently been established that where one party is precluded from performing his obligation through some cause beyond his own control, the law of Scotland (following Roman law) will enforce the return of any payment in advance that may have been made (*Cantiere San Rocco* v. *Clyde Shipbuilding Co.*, 1923, S.C. [H.L.] 105); whereas English authorities hold that matters must remain as they were when the invalidating causes became operative (*Krell* v. *Henry*, 1903, 2 K.B. 740).

Sale of Goods.—In the contract of sale of goods the law of Scotland, until 1894, held that the property in goods sold did not pass until delivery. But in this respect the law has been completely altered by the Sale of Goods Act 1893, which provides rules on this subject applicable to both countries, and derived from English law. The Act, however, leaves certain points of variance. Thus s. 4, providing for a memorandum in writing in sales of the value of £10, is not applicable to Scotland, where parole evidence is in all cases sufficient. In cases of breach of contract the distinction between conditions and warranties, in the technical meaning given to these terms in English law, is not recognized in Scotland. It may be said that in English law the remedies of a buyer depend upon whether the seller's failure is in fulfilment of a condition or of a warranty; in Scots law the question is whether the seller's failure is, in the particular circumstances, material.

In the law of securities the conveyancing expedients for the constitution of a security over land differ so greatly that any comparison would be futile. In the constitution of securities over movables there is no provision, in Scotland, in any way analogous to the Bills of Sale Act 1882. And it is established law, with exceptions of little importance, that no security over movables which will give the creditor any preference in bankruptcy, or in a question with other creditors using diligence, can be created without delivery of the subjects, actual or constructive. Attempts to evade the rule by framing the security as a sale have met with little success. And the English law of equitable mortgage finds no counterpart in Scotland. At least since the decision in *Christie* v. *Ruxton* (1862, 24 D. 1182) it has been regarded as settled law that the mere deposit of documents of the nature of title deeds, which are not negotiable instruments, or documents of title under the Factors Acts (as to which the law is not free from doubt) will not give the party who takes them any security. And a memorandum or written statement of the object of the deposit, unless it amounts to an assignation of the property represented by the titles, does not affect the question.

Tort.—Apart from the mercantile contracts already mentioned the law as to liability for wrongful and negligent acts is the subject in which there is the least difference between England and Scotland. The provisions of 9 and 10 Vict. c. 93 (Lord Campbell's Act) give a right of action to the wife, husband, parent or child of a deceased person, which approximates closely to that allowed by the common law of Scotland.

In the case of defamation the distinctions are of some importance. Between defamation in "words" (slander) and defamation in "writing" (libel) the law of Scotland draws no distinction. It treats either merely as a civil wrong, not, except in the special case of parliamentary elections, as a criminal offence. It is not necessary, in any case, to prove that special damage has resulted, though this will be taken account of in the award of damages. And on the principle of allowing *solatium* for injured feelings an action is admitted in Scots law even although the defamatory statement is not made known to anyone except the person himself.

Criminal Law.—In criminal law the English law of high treason was expressly made applicable to Scotland by 7 Anne ch. 21. With regard to other crimes the terms used often differ, but there is no case of serious importance in which an act is criminal in the one country and not in the other. The procedure, however, differs greatly. Private prosecution, at the instance of the injured party, though competent, is in Scotland very rare except in minor statutory offences. It requires the consent and concurrence of the Crown (given through the agency of the lord advocate, or, in minor offences, of the procurator fiscal) and, although the High Court of Justiciary has power to dispense with this requirement, the case of Coats (1909, S.C. [J] 29) is the only modern instance of the exercise of that power. There is no institution in Scotland analogous to the English grand jury; the question whether there is a *prima facie* case for prosecution being always one for the discretion of the criminal authorities. In the trial of criminal offences the jury in Scotland numbers 15, as opposed to the English 12, and the verdict may be given by a majority. The Scotch verdict of "not proven," having the same legal effect as a verdict of "not guilty," has no English counterpart. A defect in the Scotch legal system, which had no provision for any public inquiry in cases of death under doubtful or suspicious circumstances, analogous to the English coroner's inquest, has been partially remedied by the Fatal Accidents Inquiry Acts of 1895 and 1906, under which a public inquiry by a sheriff and jury is held in all cases of fatal accidents in any industrial employment, and may be directed by the lord advocate in the case of any sudden or suspicious death.

Bibliography.—For the law of Scotland generally, *see* Stair, *Institutions* (1681; More's ed. 1832); Erskine, *Institutes* (1773; new ed. 1871); Bell, *Principles* (1824; 10th ed. 1899); Bell, *Commentaries* (1810; 7th ed. 1894); Green, *Encyclopaedia of the Law of Scotland* (3rd ed. in course of publication). (W. M. G.)

SCOTT, ALEXANDER (*fl.* 1550), Scottish poet, was probably a Lothian man, but particulars of his origin and of his life are entirely wanting. It is only by gathering together a few scraps of internal evidence that we learn that his poems were written between 1545 and 1568 (the date of the Bannatyne MS., the only MS. authority for the text). Allan Ramsay was the first to bring Scott's work to the notice of modern readers, by printing some of the poems in his *Ever Green*.

No early Scots poet comes nearer than Scott to the quality of the Caroline love-lyric. His *Justing and Debait vp at the Drum betwix W*[*illiam*] *Adamsone and Johine Sym* follows the literary tradition of *Peblis to the Play* and *Christis Kirk on the Grene*. He has left verse-renderings of the 1st and 50th Psalms.

The first collected edition was printed by D. Laing in 1821; a second was issued privately at Glasgow in 1882. The latest edition is that by James Cranstoun (Scottish Text Society, 1 vol., 1896).

SCOTT, CHARLES PRESTWICH (1846–), British editor and journalist, born at Bath, Somersetshire, on Oct. 26, 1846, was the youngest son of Russell Scott. He was educated privately and at Corpus Christi college, Oxford, where he graduated with a first class in 1869. After training under Alexander

Russell of *The Scotsman,* he, in 1871, began a long connection with *The Manchester Guardian,* of which his brother-in-law, J. E. Taylor, was proprietor. He himself became editor in 1872, and, after the death of Taylor in 1905, also chief proprietor. He enlisted the services of W. T. Arnold and many of the leading critics of literature, art and music of two generations, so that the paper became one of the foremost journals of the day. Gradually developing from Whiggism to advanced Liberalism, *The Manchester Guardian,* as directed by Scott, was always sober in tone and scrupulous in policy. He retired in 1929. Always active in local politics, after three unsuccessful contests for the representation of North-East Manchester, Scott was elected Liberal M.P. for the Leigh division of Lancashire in 1895 and sat till 1906.

SCOTT, CYRIL MEIR (1879–), English musical composer, pianist and author, was born at Oxton, Birkenhead, on Sept. 27, 1879, and studied music at the Hoch conservatorium, Frankfurt-on-Main. On his return to England, Hans Richter produced his orchestral Heroic Suite at Liverpool, and an overture to *Pelléas and Mélisande* was shortly afterwards played at Frankfurt, but both of these and several of his other early works were afterwards withdrawn by the composer as immature. Among the more important of his works may be named a piano concerto, a violin concerto, a piano quartet, a piano quintet, a violin sonata, many pianoforte pieces, three operas and many songs. He has also written and published some verse and a volume of autobiography, *My Years of Indiscretion.*

SCOTT, SIR GEORGE GILBERT (1811–1878), English architect, was born in 1811 at Gawcott near Buckingham, where his father was rector; his grandfather, Thomas Scott (1747–1821), was a well-known commentator on the Bible. Scott was apprenticed to a London architect, filled various staff posts, and designed his first church in 1838. But his real artistic education dates from his study of Pugin's works on mediaeval architecture. The first result of this new study was his design for the Martyrs' Memorial at Oxford, erected in 1840, a clever adaptation of the late 13th-century crosses in honour of Queen Eleanor.

In 1844 Scott won the first premium in the competition for the new Lutheran church at Hamburg, a noble building with a very lofty spire, designed strictly in the style of the 13th century. In 1847 he was employed to renovate and refit Ely cathedral, the first of a long series of English cathedral and abbey churches which passed through his hands. In 1851 he visited and studied the architecture of the chief towns in northern Italy. In 1856 a competition was held for designs of the new government offices in London; Scott obtained the third place in this, but the work was afterwards given to him on the condition (insisted on by Lord Palmerston) that he should make a new design, not Gothic, but Classic or Renaissance in style. In 1862–1863 he was employed to design and construct the Albert Memorial, a costly and elaborate work, in the style of a magnified 13th-century reliquary or ciborium, adorned with many statues and reliefs in bronze and marble. On the partial completion of this he was knighted. In 1866 he competed for the new London law-courts, but the prize was adjudged to his old pupil, G. E. Street. In 1873, owing to illness caused by overwork, Scott spent some time in Rome and other parts of Italy. The mosaic pavement which he designed for Durham cathedral soon afterwards was the result of his study of the 13th-century mosaics in the old basilicas of Rome. He died on March 27, 1878.

An incomplete list of his works from 1847 in the *Builder* for 1878 (p. 360) ascribes to Scott 732 buildings with which he was connected as architect, restorer or the author of a report. These include 29 cathedrals, British or colonial, 10 minsters, 476 churches, 25 schools, 23 parsonages, 58 monumental works, 25 colleges or college chapels, 26 public buildings, 43 mansions and a number of small ecclesiastical accessories. While a member of the Royal Academy, Scott held for many years the post of professor of architecture, and gave a long series of able lectures on mediaeval styles, which were published in 1879. He wrote a work on *Domestic Architecture,* and a volume of *Personal and Professional Recollections,* which, edited by his eldest son, was published in 1879.

SCOTT, SIR GILES GILBERT (1880–), British architect, born Nov. 9, 1880, was the son of George Gilbert Scott and grandson of Sir George Gilbert Scott, R.A. Educated at Beaumont College, Old Windsor, he began to practise in London in 1902. In the following year his designs for the projected cathedral at Liverpool, the expression of the architect's hope for a revival of Gothic architecture through the true understanding of its spirit, were accepted, but, in consideration of his youth, G. F. Bodley, R.A., was associated with him as joint architect. In July 1904 the foundation was laid by King Edward, the corner stone of the chapter-house by the Duke of Connaught in 1906, and the Lady Chapel was completed in 1910. After some delay occasioned by the World War, the consecration took place on July 19, 1924, in the presence of King George V. and Queen Mary. Designed in Gothic style it was the first Anglican cathedral built in the northern provinces since the Reformation, and when completed, will be the largest church in Great Britain. The design for the tower was considerably altered in 1924. The exterior is of red sandstone and the building is specially adapted for lighting by electricity. Its massive bulk dominates the city and the seaway. Chief among the other works of the architect, which are almost entirely ecclesiastical, are the Church of the Annunciation, Bournemouth; St. Manghold's Church and Presbytery, Ramsey, Isle of Man; the Chapel of the Visitation Convent, Harrow; new buildings at Clare College Cambridge, and many war memorials. Scott also did restoration work on Chester Cathedral. He was elected A.R.A. in 1918, R.A. in 1922, and was president of the Architectural Association in 1920–21. He was knighted after the consecration of Liverpool Cathedral in 1924. (*See* ARCHITECTURE.)

SCOTT, SIR PERCY MORETON (1853–1924), British sailor, was born on July 10, 1853. He entered the navy in 1866 and served in the Ashantee War (1873–74), the Congo Expedition 1875 and the Egyptian campaign of 1882. In 1893 he was promoted to captain and in the following year became a member of the ordnance committee. In 1896 he took command of the cruiser "Scylla" and came into prominence as the inventor of the "dotter" and "deflection teacher" devices, which signified an important advance in the evolution of naval gunnery. He served with the Naval Brigade in the South African War, when he got the naval 6-in. guns up to Ladysmith and in 1900 assisted the International Brigade in China during the Boxer Rebellion. In 1903 he took command of the gunnery school ship "Excellent," in 1905 became rear-admiral and inspector of target practice and in 1908 was promoted vice-admiral. Created K.C.B. in 1910, he was made a baronet in 1913. He retired in 1913 with the rank of admiral. On the outbreak of the World War he returned to the service and was for some time in charge of the air force defences of London. Sir Percy Scott later became an advocate of the submarine, and was strongly opposed to the building of battleships. He died on Oct. 18, 1924. He wrote *Fifty Years in the Royal Navy* (1919).

SCOTT, ROBERT (1811–1887), English divine and lexicographer, was born on Jan. 26, 1811, at Bondleigh in Devonshire. Educated at Shrewsbury school and Christ Church, Oxford, he was elected fellow of Balliol, where he was tutor from 1835 to 1840. In 1854 he was elected master of Balliol. This office he held, together (from 1861) with that of the professorship of the exegesis of Holy Scriptures, down to 1870, when he became dean of Rochester. As a Greek scholar, he had few equals among his contemporaries. His great achievement was his collaboration with Dean Liddell in the Greek lexicon (1843), of which a new edition, revised by H. S. Jones and R. McKenzie, was published in 1925. He died at Rochester on Dec. 2, 1887.

SCOTT, ROBERT FALCON (1868–1912), British sailor and explorer, was born at Devonport on June 6, 1868. Educated at Stoke Damerel and Stubbington House, Fareham, he passed into H.M.S. "Britannia" in 1880, and in 1882 became a midshipman on the "Boadicea." In 1897 he was promoted first lieutenant, and two years later he was recommended as commander of the National Antarctic Expedition. On taking up his duties in the "Discovery," in 1900, he was promoted commander. During the four years which followed, Scott proved both an intrepid and able leader, and a competent scientific investigator; and on his return in 1904 he was promoted to the rank of captain. For the next six years he served in the navy, commanding successively,

the "Victorious," the "Essex," and the "Bulwark," until, in 1909, he announced his intention of organizing another Antarctic expedition, for the purpose of continuing the work of the "Discovery" and of reaching the South Pole.

Backed financially by the British and Dominion Governments, Scott set sail in June 1910 in the "Nova Terra," and in Nov. 1911, began his southern sledge journey. Though delayed by bad weather, Scott and his four companions reached the Pole on Jan. 18, 1912, to find that they had been forestalled by Amundsen. Sickness, insufficiency of food, and the severity of the weather, made travelling very slow on the return journey, and on Feb. 17, Petty Officer Evans broke down under the strain and died. A month later, Oates, who was too ill to travel further, walked out into a blizzard, hoping, by his sacrifice, to save his companions; but the weather prevented all possibilities of advancing, and the remainder of the party perished on or about March 27, 1912. On Nov. 12, 1912, a search party found Scott's tent, containing the bodies of Scott, Dr. E. A. Wilson and Lieut. H. R. Bowers, as well as Scott's records and diaries, in which was given a full account of the journey and the deaths of Capt. Oates and Petty Officer Edgar Evans. A memorial service was held in St. Paul's cathedral, London, on Feb. 14, 1913, and a Mansion House fund was subsequently raised to make provision for the surviving relatives of the lost explorers. The rank and precedence of the wife of a K.C.B. were by royal warrant conferred on Captain Scott's widow.

SCOTT, SIR WALTER, Bart. (1771–1832), Scottish poet and novelist, was born at Edinburgh on Aug. 15, 1771. He came of an old Border family, and it was his pride in their real or supposed feudal dignity and their rough marauding exploits that first directed him to the study of Border history and poetry, the basis of his fame as a poet and romancer. His father, Walter Scott, a writer to the signet (or attorney) in Edinburgh—the original of the elder Fairford in *Redgauntlet*—was the first of the family to adopt a town life or a learned profession. His mother was the daughter of Dr. John Rutherford, a medical professor in the University of Edinburgh, who also traced descent from the chiefs of famous Border clans.

Scott's health in boyhood was uncertain; an attack of fever in infancy had left him permanently lame, and his nature was so lively and excitable that it was considered dangerous to press him and prudent rather to keep him back. He was therefore left very much to himself in the matter of reading, and began at an early age to accumulate the romantic lore of which he afterwards made such splendid use. At ten his collection of chap-books and ballads had reached several volumes, and he was a connoisseur in various readings. Thus he took to the High School, Edinburgh, when he was strong enough to be put in regular attendance, an unusual store of miscellaneous knowledge and an unusually quickened intelligence. Throughout his school days and afterwards when he was apprenticed to his father, attended university classes, read for the bar, took part in academical and professional debating societies, Scott steadily and ardently pursued his own favourite studies. He was still a schoolboy when he mastered French sufficiently well to read through collections of old French romances, and not more than 15 when, attracted by translations to Italian romantic literature, he learnt the language in order to read Dante and Ariosto in the original. In one of the literary parties brought together to lionize Burns, when the peasant poet visited Edinburgh, the boy of 15 was the only member of the company who could tell the source of some lines affixed to a picture that had attracted the poet's attention—a slight but significant evidence both of the width of his reading and of the tenacity of his memory. But he was far from being a cloistered student, absorbed in his books. In spite of his lameness and his serious illnesses in youth, his constitution was naturally robust, his disposition genial, his spirits high: he was always well to the front in the fights and frolics of the High School, and a boon companion in the "high jinks" of the junior bar. At home he had to behave as became a member of a Puritanic, somewhat ascetic, well-ordered Scottish household, but from any tendency to the pedantry of over-culture he was effectually saved by the rougher and manlier spirit of his professional comrades. They were the first mature audience on which he experimented, and it was to this market that he brought the harvest of the vacation rambles which it was his custom to make every autumn for seven years after his call to the bar and before his marriage. His staid father did not much like these escapades, and told him bitterly that he seemed fit for nothing but to be a "gangrel scrape-gut." But, as the companion of "his Liddesdale raids" happily put it, "he was *makin' himsell* a' the time."

His father intended him originally to follow his own business, and he was apprenticed in his 16th year; but he preferred the upper walk of the legal profession, and was admitted a member of the faculty of advocates in 1792. He seems to have read hard at law for four years at least, but almost from the first to have limited his ambition to obtaining some comfortable appointment such as would leave him a good deal of leisure for literary pursuits. In this he was not disappointed. In 1799 he obtained the office of sheriff-depute of Selkirkshire, with a salary of £300 and very light duties. In 1806 he obtained the reversion of the office of clerk of session, which kept him hard at work, his biographer estimates, for at least three or four hours daily during six months out of the twelve, while the court was in session. He discharged these duties faithfully for 25 years, during the height of his activity as an author. He did not enter on the emoluments of the office till 1812, but from that time he received from the clerkship and the sheriffdom combined an income of £1,600 a year, being thus enabled to act in his literary undertakings on his often-quoted maxim that "literature should be a staff and not a crutch."

The Poems.—It was as a poet that he was first to make a literary reputation. According to his own account, he was led to adopt the medium of verse by a series of accidents. The story is told by himself at length and with his customary frankness and modesty in the *Essay on Imitations of the Ancient Ballad,* prefixed to the 1830 edition of his *Border Minstrelsy,* and in the 1830 introduction to the *Lay of the Last Minstrel.* The first link in the chain was a lecture by Henry Mackenzie on German literature, delivered in 1788. This apprized Scott that there was a fresh development of romantic literature in German, and while he was in the height of his enthusiasm for the new German romance, Mrs. Barbauld visited Edinburgh, and recited an English translation of Bürger's *Lenore.* Scott was moved to attempt such poetry himself, and the impulse was strengthened by his reading Lewis's *Monk* and the ballads in the German manner interspersed through the work. He hastened to procure a copy of Bürger, at once executed translations of several of his ballads, published *The Chase,* and *William and Helen,* in a thin quarto in 1796 (his ambition being perhaps quickened by the unfortunate issue of a love affair), and was much encouraged by the applause of his friends. Soon after he composed *Glenfinlas, The Eve of St. John,* and the *Gray Brother,* which were published in Lewis's collection of *Tales of Wonder* (2 vols., 1801). But he soon became convinced that "the practice of ballad-writing was out of fashion," and his study of Goethe's *Götz von Berlichingen,* of which he published a translation in 1799, gave him wider ideas. Why should he not do for ancient Border manners what Goethe had done for the ancient feudalism of the Rhine? He was engaged at the time preparing a collection of the *Minstrelsy of the Scottish Border,* the first instalment of which was published in two volumes in 1802, and was still hesitating about subject and form for a large original work, when chance at last threw in his way both a suitable subject and a suitable metrical vehicle. The countess of Dalkeith, happening to hear the legend of a tricksy hobgoblin named Gilpin Horner, asked Scott to write a ballad about it. He agreed with delight, and the subject grew in his fertile imagination, till incidents enough had gathered round the goblin to furnish a framework for his long-designed picture of Border manners. At the same time a friend of his who had met Coleridge in Malta brought home sufficient reminiscences of the still unpublished poem of *Christabel* to con-

vey to Scott that its metre was the very metre of which he had been in search. Scott introduced still greater variety into the four-beat couplet; but it was to *Christabel* that he owed the suggestion, as one line borrowed whole and many imitated rhythms testify.

The *Lay of the Last Minstrel* appeared in Jan. 1805, and at once became widely popular. Its success finally decided that literature was to be the main business of Scott's life, and he proceeded to arrange his affairs accordingly. Since his marriage in 1797 with Charlotte Charpentier, daughter of a French refugee, his chief residence had been at Lasswade, about six miles from Edinburgh. But on a hint from the lord-lieutenant that the sheriff must live at least four months in the year within his county, and that he was attending more closely to his duties as quartermaster of a mounted company of volunteers than was consistent with the proper discharge of his duties as sheriff, he had moved his household in 1804 to Ashestiel. When his uncle's bequest fell in, he determined to buy a small property on the banks of the Tweed within the limits of his sheriffdom. There, within sight of Newark castle and Bowhill, he proposed to live like his ancient minstrel, as became the bard of the clan, under the shadow of the great ducal head of the Scotts. But this plan was deranged by an accident. It so happened that an old schoolfellow, James Ballantyne (1772–1833), a printer in Kelso, whom he had already befriended, transplanted to Edinburgh, and furnished with both work and money, applied to him for a further loan. Scott declined to lend, but offered to join him as sleeping-partner. Thus the intended purchase money of Broadmeadows became the capital of a printing concern, of which by degrees the man of letters became the overwrought slave, milch-cow and victim.

When the *Lay* was off his hands, Scott's next literary enterprise was a prose romance—a confirmation of the argument that he did not take to prose after Byron had "*bet* him," as he put it, in verse, but that romance writing was a long-cherished purpose. He began *Waverley*, but a friend to whom he showed the first chapters decided that the work was deficient in interest and unworthy of the author of the *Lay*. Scott accordingly laid *Waverley* aside. We may fairly conjecture that he would not have been so easily diverted had he not been occupied at the time with other heavy publishing enterprises calculated to bring grist to the printing establishment. In 1806 he collected from different publications his *Ballads and Lyrical Pieces*. Between 1806 and 1812, mainly to serve the interests of the firm, he produced his elaborate editions of Dryden (18 vols., 1808), Swift (19 vols., 1818), the Somers Tracts (13 vols., 1809–15), and the *State Papers and Letters of Sir Ralph Sadler* (2 vols., 1809).

Marmion, begun in Nov. 1806 and published in Feb. 1808, was written as a relief to "graver cares," and was even more popular than the *Lay*. Scott's resuscitation of the four-beat measure of the old "gestours" afforded a signal proof of the justness of their instinct in choosing this vehicle for their recitations. The four-beat lines of *Marmion* took possession of the public like a kind of madness, and the critics, except Jeffrey, who may have been offended by the pronounced politics of the poet, were on the whole better pleased than with the *Lay*. Scott was now *facile princeps* among living poets, and touched the highest point of prosperity and happiness. Presently after, he was irritated and tempted by a combination of little circumstances into the great blunder of his life, the establishment of the publishing house of John Ballantyne and Co. A quarrel occurred between Scott's printing firm and Constable, the publisher, who had been the principal feeder of its press. Then the tempter appeared in the shape of Murray, the London publisher, anxious to secure the services of the most popular *littérateur* of the day. The result of negotiations was that Scott set up, in opposition to Constable, the publishing house of John Ballantyne and Co., to be managed by John Ballantyne (d. 1821), James's younger brother. Scott interested himself warmly in starting the *Quarterly Review*, and in return Murray constituted Ballantyne and Co. his Edinburgh agents. Scott's trust in the Ballantynes, and in his own power to supply all their deficiencies, is as strange a piece of infatuation as any that ever formed a theme for romance or tragedy. Their devoted attachment to the architect of their fortunes and proud confidence in his powers helped forward to the catastrophe, for whatever Scott recommended they agreed to, and he was too immersed in multifarious literary work and professional and social engagements to have time for cool examination of the numerous rash speculative ventures into which he launched the firm.

The *Lady of the Lake* (May 1810) was the first great publication by the new house, and next year the *Vision of Don Roderick* followed. The *Lady of the Lake* was received with enthusiasm; it made the Perthshire Highlands fashionable for tourists, and raised the post-horse duty in Scotland; but it did not make up to Ballantyne and Co. for their heavy investments in unsound ventures. The *Edinburgh Annual Register*, meant as a rival to the *Edinburgh Review*, though Scott engaged Southey to write for it and wrote for it largely himself, proved a failure. In a very short time the warehouses of the firm were filled with unsaleable stock, but, so far from understanding the real state of their affairs, Scott considered himself rich enough to make his first purchase of land at Abbotsford. He had hardly settled there in the spring of 1812, and begun his schemes for building and planting and converting a bare moor into a richly wooded *pleasaunce*, when his business troubles began, and he found himself harassed by fears of bankruptcy. The proceeds of *Rokeby* (Jan. 1813) and of other labours of Scott's pen were swallowed up, and bankruptcy was inevitable, when Constable, still eager at any price to secure Scott's services, came to the rescue. With his help three crises were tided over in 1813.

The Novels.—It was in the midst of these embarrassments that Scott opened up the rich new vein of the Waverley novels. He chanced upon the ms. of the opening chapters of *Waverley* which he had written in 1805, and resolved to complete the story. Four weeks in the summer of 1814 sufficed for the work, and *Waverley* was published by Constable without the author's name in July. Many plausible reasons might be given and have been given for Scott's resolution to publish anonymously. The reason given by Lockhart is that he considered the writing of novels beneath the dignity of a grave clerk of the Court of Sessions. The secret was an open one to all his Edinburgh acquaintances, yet why he kept up the mystification until the disclosure of the year 1827, is easily understood. He enjoyed it, and his formally initiated coadjutors enjoyed it; it relieved him from the annoyances of foolish compliment; and it was not unprofitable—curiosity about "the Great Unknown" keeping alive the interest in his works. Meanwhile he kept on producing in his own name as much work as seemed humanly possible for an official who was to be seen every day at his post and as often in society as the most fashionable of his professional brethren. His treatises on chivalry, romance and the drama, besides an elaborate work in two volumes on Border antiquities, appeared in the same year with *Waverley*, and his edition of Swift in 19 volumes in the same week. In 1813 he published the romantic tale of *The Bridal of Triermain* in three cantos, enlarged from an earlier poem, printed in the *Edinburgh Annual Register* of 1809. The *Lord of the Isles* was published in Jan. 1815; *Guy Mannering*, written in "six weeks about Christmas," in February; and *The Field of Waterloo* in the same year. *Paul's Letters to his Kinsfolk* and *The Antiquary* appeared in 1816; the first series of the *Tales of My Landlord*, edited by "Jedediah Cleishbotham"—*The Black Dwarf* and *Old Mortality*—in the same year; *Harold the Dauntless* in 1817; the two volumes of *The Border Antiquities of England and Scotland* in 1814 and 1817. No wonder that the most positive interpreters of internal evidence were mystified. Scott's fertility is not absolutely unparalleled; Anthony Trollope claimed to have surpassed him in rate as well as total amount of production, having also business duties to attend to. But in speed of production combined with variety and depth of interest and weight and accuracy of historical substance Scott is unrivalled.

The immense strain of this double or quadruple life as sheriff and clerk, hospitable laird, poet, novelist, and miscellaneous man of letters, publisher and printer, though the prosperous excitement sustained him for a time, soon told upon his health. Early in 1817 began a series of attacks of agonizing cramp of the stomach,

which recurred at short intervals during more than two years. But his appetite and capacity for work remained unbroken. He made his first attempt at play-writing (*The Doom of Devorgoil*) as he was recovering from the first attack; before the year was out he had completed *Rob Roy,* and within six months it was followed by *The Heart of Midlothian,* which filled the four volumes of the second series of *Tales of My Landlord,* and has remained one of the most popular among his novels. *The Bride of Lammermoor, the Legend of Montrose,* forming the third series by "Jedediah Cleishbotham," and *Ivanhoe* (1820) were dictated to amanuenses, through fits of suffering so acute that he could not suppress cries of agony.

Throughout those two years of intermittent ill-health, which was at one time so serious that his life was despaired of and he took formal leave of his family, Scott's semi-public life at Abbotsford continued as usual—swarms of visitors coming and going, and the rate of production, on the whole, suffering no outward and visible check, all the world wondering at the novelist's prodigious fertility. The first of the series concerning which there were murmurs of dissatisfaction was *The Monastery* (1820); but its sequel, *The Abbot* (1820), in which Mary, Queen of Scots, is introduced, was generally hailed as fully sustaining the reputation of "the Great Unknown." *Kenilworth* (1821), *The Pirate* (1822), *The Fortunes of Nigel* (1822), *Peveril of the Peak* (1822), *Quentin Durward* (1823), *St. Ronan's Well* (1824), *Redgauntlet* (1824) followed in quick succession in the course of three years, and it was not till the last two were reached that the cry that the author was writing too fast began to gather volume. *St. Ronan's Well* was very severely criticized and condemned, yet none of Scott's stories is of more absorbing or more brilliantly diversified interest. There must, of course, always be inequalities in a series so prolonged. The author cannot always be equally happy in his choice of subject, situation and character. Naturally also he dealt first with the subjects of which his mind was fullest. But any theory of falling off or exhaustion based upon plausible general considerations has to be qualified so much when brought into contact with the facts that very little confidence can be reposed in its accuracy. *The Fortunes of Nigel* comes comparatively late in the series and has often been blamed for its looseness of construction, yet some competent critics prefer it to any other of Scott's novels. An attempt might be made to value the novels according to the sources of their materials, according as they are based on personal observation, documentary history or previous imaginative literature. On this principle *Ivanhoe* and *The Tales of the Crusaders* (1825, containing *The Betrothed* and *The Talisman*) might be adjudged inferior as being based necessarily on previous romance. But as a matter of fact Scott's romantic characters are vitalized, clothed with a verisimilitude of life, out of the author's deep, wide and discriminating knowledge of realities, and his observation of actual life was coloured by ideals derived from romance. He did not exhaust his accumulations from one source first and then turn to another, but from first to last drew from all as the needs of the occasion happened to suggest.

During the years 1821–25 he edited Richard Franck's *Northern Memoirs* (1821), *Chronological Notes of Scottish Affairs from the Diary of Lord Fountainhall* (1822), *Military Memoirs of the Great Civil War* (1822), and *The Novelists' Library* (10 vols., 1821–24), the prefatory memoirs to which were separately published in 1828.

Financial Ruin.—Towards the close of 1825, after 11 years of brilliant and prosperous labour, encouraged by constant tributes of admiration, homage and affection such as no other literary potentate has ever enjoyed, realizing his dreams of baronial splendour and hospitality on a scale suited to his large literary revenues, Scott suddenly discovered that the foundations of his fortune were unsubstantial. He had imagined himself clear of all embarrassments in 1818, when all the unsaleable stock of John Ballantyne and Co. was bargained off to Constable for Waverley copyrights, and the publishing concern was wound up. Apparently he never informed himself accurately of the new relations of mutual accommodation on which the printing firm then entered with the great but rashly speculative publisher, and drew liberally for his own expenditure against the undeniable profits of his novels without asking any questions, trusting blindly in the solvency of his commercial henchmen. Unfortunately, "lifted off their feet" by the wonderful triumphs of their chief, they thought themselves exempted like himself from the troublesome duty of inspecting ledgers and balancing accounts, till the crash came. From a diary which Scott began a few days before the first rumours of financial difficulty reached him we know how he bore from day to day the rapidly unfolded prospect of unsuspected liabilities. "Thank God," was his first reflection, "I have enough to pay more than 20s. in the pound, taking matters at the worst." But a few weeks revealed the unpleasant truth that, owing to the way in which Ballantyne and Co. were mixed up with Constable and Co., and Constable with Hurst and Robinson, the failure of the London house threw upon him personal responsibility for £130,000.

How Scott's pride rebelled against the dishonour of bankruptcy, how he toiled for the rest of his life to clear off this enormous debt, declining all offers of assistance and asking no consideration from his creditors except time, and how nearly he succeeded, is one of the most familiar chapters in literary history, and would be one of the saddest were it not for the heroism of the enterprise. His wife died soon after the struggle began, and he suffered other painful bereavements; but, though sick at heart, he toiled on indomitably, and, writing for honour, exceeded even his happiest days in industrious speed. If he could have maintained the rate of the first three years, during which he completed *Woodstock* (1826); *Chronicles of the Canongate* (1827), which included three tales—"The Highland Widow," "The Two Drovers" and "The Surgeon's Daughter"; *The Fair Maid of Perth* (1828, in the second series of *Chronicles of the Canongate*); *Anne of Geierstein* (1829); the *Life of Napoleon* (9 vols., 1827); part of his *History of Scotland* (2 vols., 1829–30, for *Lardner's Cabinet Cyclopaedia*); the Scottish series of *Tales of a Grandfather* (four series, 1828–29–30–31), besides several magazine articles, some of them among the most brilliant of his miscellaneous writings, and prefaces and notes to a collected edition of his novels—if he could have continued at this rate he might soon have freed himself from all his encumbrances. The result of his exertions from Jan. 1826 to Jan. 1828 was nearly £40,000 for his creditors. But the terrific labour proved too much even for his endurance. Ugly symptoms began to alarm his family in 1829, and in Feb. 1830 he had his first stroke of paralysis. Still he was undaunted, and not all the persuasions of friends and physicians could induce him to take rest. "During 1830," Lockhart says, "he covered almost as many sheets with his ms. as in 1829," the new introductions to a collected edition of his poetry and the *Letters on Demonology and Witchcraft* being amongst the labours of the year. He had a slight touch of apoplexy in November and a distinct stroke of paralysis in the following April; but, in spite of these warnings and of other bodily ailments, he had two more novels, *Count Robert of Paris* and *Castle Dangerous* (constituting the fourth series of *Tales of My Landlord*), ready for the press by the autumn of 1831. He would not yield to the solicitations of his friends and consent to try rest and a change of scene, till fortunately, as his mental powers failed, he became possessed of the idea that all his debts were at last paid and that he was once more a free man. In this belief he happily remained till his death. When it was known that his physicians recommended a sea voyage for his health, a Government vessel was put at his disposal, and he cruised about in the Mediterranean and visited places of interest for the greater part of a year before his death. But, when he felt that the end was near, he insisted on being carried across Europe that he might die on his beloved Tweedside at Abbotsford, where he expired on Sept. 21, 1832. He was buried at Dryburgh Abbey.

Scott's wife had died in 1826. His eldest son, Walter, succeeded to the baronetcy which had been conferred on his father in 1820, and the title became extinct on his death in 1847; the elder daughter Charlotte Sophia (d. 1837) was the wife of his biographer, J. G. Lockhart (*q.v.*); and their daughter Charlotte (d. 1858) married J. R. Hope-Scott, and was the mother of Mary Monica, wife of the Hon. J. C. Maxwell, who in 1874 took the additional name of Scott on his marriage with the heiress of

Abbotsford. Mrs. Maxwell-Scott inherited some of the family literary talent, and among other books wrote two volumes about Abbotsford (1893 and 1897).

BIBLIOGRAPHY.—*The Miscellaneous Prose Works of Sir Walter Scott* (6 vols., 1827) were subsequently printed in 30 vols. (1834–71) and in 3 vols. (1841–47). The collected editions of the novels and tales are very numerous. Among them are that known as the "author's favourite edition" (48 vols., 1829–33), for which Scott wrote new prefaces and notes, and the "Border" edition (48 vols., 1892–94), with introductory essays and notes by A. Lang. His *Poetical Works* were printed in 12 vols. (1820); they were edited by J. G. Lockhart (12 vols., 1833–34); by F. T. Palgrave for the "Globe" edition (1866); by W. Minto (2 vols., 1888); by J. Logie Robertson (Oxford complete edition, 1904). Many of the novels have been adapted for the stage, the most famous of these dramatizations being the libretto of Donizetti's *Lucia di Lammermoor* and the *Ivanhoe* of Sir Arthur Sullivan and J. R. Sturgis. His *Minstrelsy of the Scottish Border* (3 vols., 1802–03) was edited (4 vols., 1902) by T. F. Henderson.

The standard life by his son-in-law, J. G. Lockhart, *Memoirs of the Life of Sir Walter Scott* (7 vols., 1837–38), was supplemented by the publication (2 vols., 1890) of Scott's *Journal*, covering the years from 1825 to 1832, and of his *Familiar Letters* (2 vols., 1894), both edited by David Douglas. *See* also James Hogg, *The Domestic Manners and Private Life of Sir Walter Scott* (1834), and R. P. Gillies, *Recollections of Sir Walter Scott* (1837). Shorter lives are by R. H. Hutton ("English Men of Letters," 1878); G. E. B. Saintsbury ("Famous Scots" Series, 1897); Andrew Lang ("Literary Lives," 1906); G. le Grys Norgate (1906), and J. Buchan (1925). For the Ballantyne controversy *see* also *The Ballantyne Press and its Founders* (1909). *See* also W. Brewer, *Shakespeare's Influence on Sir Walter Scott* (1925); A. Caplan, *The Bibliography of Sir Walter Scott* (1928); W. S. Crockett, *The Religion of Sir Walter Scott* (1929).

SCOTT, WINFIELD (1786–1866), American general, was born near Petersburg (Va.) on June 13, 1786. In 1805 he entered the College of William and Mary where he studied law. In 1807 he removed to Charleston (S.C.), but as war with England seemed imminent he soon left for Washington and offered his services. In 1808 he was commissioned as a captain of artillery, recruited a company in Richmond and Petersburg, and was ordered to New Orleans. In July 1812, as a lieutenant-colonel of artillery, he was sent to the Niagara frontier and fought at Queenston, where he was taken prisoner. He was exchanged in Jan., 1813, became colonel in the following March, was promoted to the rank of brigadier-general in March 1814, and in July received the brevet of major-general. In the battles of Chippewa (July 5, 1814) and Lundy's Lane (July 25) he took a conspicuous part, and was twice wounded in the Lundy's Lane engagement. For his services he was presented with a gold medal by Congress and with a sword by the State of Virginia.

Among the difficult tasks that he was called upon to perform between 1815 and 1861, for the last 20 years of which period he was the commanding general of the United States Army, were: an expedition to the Middle West in 1832, where, after the end of the Black Hawk War, he negotiated treaties of peace with the Sauk, Fox, Winnebago, Sioux, and Menominee Indians; a journey to Charleston to watch the progress of the nullification movement, and to strengthen the garrisons of the forts in the harbour; an expedition in 1836 against the Seminole Indians in Florida; the supervision of the removal in 1838 of the Cherokee Indians from Georgia, North Carolina, Alabama and Tennessee to the reservation set apart for them by treaty west of the Mississippi river; a visit to the Niagara river in 1838 to put an end to the acts by Canadian insurgents in violation of American neutrality; a similar mission to Maine in 1839 to restore tranquillity between the citizens of Maine and New Brunswick, who were disputing the possession of land along the Aroostook river; and a journey to the north-west in 1859 to adjust a dispute between American and British officers concerning the joint occupation of San Juan island in Puget sound.

His greatest achievement was the brilliant Mexican campaign of 1847. As the senior officer of the army, he was placed in command of the invading expedition, and after capturing Vera Cruz (March 29, 1847), and winning victories at Cerro Gordo (April 18), Contreras-Churubusco (Aug. 19–25), Molino del Rey (Sept. 8), and Chapultepec (Sept. 13), he crowned his campaign by the capture, on Sept. 14, of the Mexican capital. In March 1848 he received a vote of thanks from Congress, which ordered a gold medal to be struck in commemoration of his services. His nomination for the presidency by the Whigs had been suggested in 1839 and in 1848, and in 1852 he received it; but the Whigs, divided on the slavery question, gave only half-hearted support to their compromise platform; and Scott made several unfortunate extemporaneous addresses. He received the electoral votes of only Kentucky, Virginia, Massachusetts and Vermont. This defeat, however, detracted nothing from his popularity, and in 1852 the brevet rank of lieutenant-general was created specially for him. At the outbreak of the Civil War, though a Virginian, he remained at the head of the United States armies and directed operations from Washington until Nov. 1861. He then visited Europe for a short time, and after returning wrote his *Memoirs*, published in 1864. He died at West Point (N.Y.) on May 29, 1866.

Mansfield, *Life and Military Services of General Scott* (1862); and Marcus J. Wright, *General Scott* (1894), in the "Great Commanders" series.

SCOTTISH LITERATURE. In a survey of the whole stream of Scottish literature two main currents may be recognized, the one *literary* and often of an artificial or academic type; the other *popular*. The former is represented by the group known as the Scottish Chaucerians, by the 17th century court poets, by the "English" writings of Edinburgh *literati* of the 18th century; the latter by the domestic and "rustic" muse from *Christis Kirk on the Grene* to the work of the 18th century revival begun in Ramsay. There is, of course, frequent interaction between these two movements, but recognition of their separate development is necessary to the understanding of such contemporary contrasts as the *Thrissil and the Rois* and *Peblis to the Play,* Drummond and Montgomerie, Ramsay and Hume. In our own day, when the literary medium of Scotland is identical with that of England, the term Scottish literature has been reserved for certain dialectal revivals, more or less bookish in origin, and often as artificial and as unrelated to existing conditions as Chaucerian "Ynglis" of the 15th century was to the popular speech of that time.

IN ENGLISH

The Early Period.—Down to the earlier decades of the 15th century the vernacular remains show the main characteristics of "Northern English," and deal with the familiar mediaeval kinds of romance and rhymed chronicle. After the Wars of Independence a national or Scottish sentiment is discernible, but it does not colour the literature of this age as it does that of later periods when political and social conditions had suffered serious change.

The earliest extant verse has been associated with Thomas of Erceldoune (*q.v.*), called The Rhymer, but the problem of the Scot's share in reworking the Tristram saga is in some important points undetermined. Uncertainty also hangs round the later Huchown (*q.v.*). Contemporary with the work of the latter are a few anonymous fragments such as the verses on the death of Alexander II., first quoted by Wyntoun in the 15th century, and the snatches on the "Maydens of Englelonde" and "Long beerdys," quoted by Fabyan. The type of alliterative romance shown in the work ascribed to Huchown continued to be popular throughout the period (e.g., *The Knightly Tale of Golagros and Gawane*), and lingered on in the next in *The Buke of the Howlat* by Holland (*q.v.*), the anonymous *Rauf Coilȝear* of the third quarter of the 15th century and in a few pieces of burlesque. Independent of this group of alliterative romances is the not less important body of historical verse associated with the names of John Barbour (*q.v.*), Andrew of Wyntoun, and, in the middle period, Harry the Minstrel (*q.v.*). Barbour, called the father of Scottish poetry, apparently for no other reason than that he is the oldest writer who has held place in popular esteem, is without literary influence. Later political fervour has grouped him with the author of the *Wallace*, and treated the unequal pair as the singers of a militant patriotism, but the "Scottish prejudice" which Burns tells us was "poured" into his veins from the *Wallace* is not obvious in the *Brus*.

The Middle Period.—To this period (extending, roughly,

throughout the 15th and 16th centuries) belongs the important group of Middle Scots "makars" or poets who, in the traditional phrase of the literary historians, made "the Golden Age of Scottish Poetry." It is in the writings of this time that we find the practice of the artificial literary dialect known as Middle Scots; but there is also in this period the first clear indication of other literary types of great prospective interest. The prevailing influence in the writers of greater account is Chaucerian. These writers, to whom the name of "The Scottish Chaucerians" has been given, carried over from the south much of the diction and not a little of the literary habit of the master-poet. In these respects they are superior to Lydgate, Occleve and other southern contemporaries; and not rarely they approach Chaucer in sheer accomplishment. The first example of this new style is the *Kingis Quair* of James I. (*q.v.*), in which the indebtedness, even when full allowance is made for the young poet's individuality, is direct and clear. The language, like that of the later *Lancelot of the Laik* and the *Quare of Jelousy,* represents no spoken dialect. Whether it is to be explained by the deliberate adoption of southern literary forms by the author, which his enthusiasm for Chaucer and the circumstances of his sojourn in England made inevitable, or whether the single text is a Scottish scribe's rendering, is still a problem. The balance of evidence is in favour of the former, which is the traditional view.

The later Chaucerian type is less directly derivative in its treatment of allegory and in its tricks of style, and is less southern in its linguistic forms. The greater poets who represent this type are Robert Henryson, William Dunbar, Gavin Douglas and Sir David Lyndsay. A critical tradition has exaggerated the importance of the minor writers who shared in this poetical outburst. Of some of the best known minors, such as Walter Kennedy (*q.v.*) and Quintyn Schaw, it would be hard to say that they are not as dull as their southern contemporaries. The greater portion of this Middle Scots "Chaucerian" literature is courtly in character, in the literary sense that it continues the verse of the *cours d'amour* type; and in the personal sense that it was directly associated with the Scottish court and conditioned by it. What is not strictly allegorical after the fashion of the *Romaunt of the Rose* or Chaucer's exercises in that kind is for the most part occasional, dealing with courtiers' sorrow and fun, with the conventional plaints on the vanity of the world and with pious ejaculation. Even Henryson, perhaps the most original of these poets, is in his most original pieces strongly "Chaucerian," notably in his remarkable series of *Fables* and in his *Testament of Cresseid;* and in the satire and Reformation heat of Lyndsay we have the old manner persisting in his *Testaments* and in his tale of *Squyer Meldrum.* There are, as might be expected, points of contact between the work of the "makars" and the more native and "popular" material. Each of the greater poets has left one example of the old manner of the alliterative romance-poem; but the fact that in each case their purpose is strongly burlesque is significant of the change in literary outlook.

The non-Chaucerian verse of this period is represented by (a) alliterative romance-poems and (b) verse of a rustic and domestic character. Of the historical romance-poem there is little or nothing beyond Henry the Minstrel's *Wallace* (*supra*). Pieces of the general description of Holland's (*q.v.*) *Buke of the Howlat* and the anonymous poems *The Awntyrs of Arthur, Rauf Coilȝear* and *The Pistill of Susan* represent outworn forms. Strong as the Chaucerian influence was, it was too artificial to change the native habit of Scots verse; and though it helps to explain much in the later history, it offers no key to the main process of succeeding centuries. Our knowledge of the non-Chaucerian material, as of the Chaucerian, is chiefly derived from the manuscript collections of Asloan, Bannatyne (*q.v.*) and Maitland (*q.v.*). The historical student will find anticipations of the manner of Ramsay, Fergusson and Burns, which criticism has too often treated as the exclusive expression of later Scotticism. It would not be difficult to show that the reaction in the 18th century against literary and class affectation (however editorial and bookish it was in the choice of subjects and forms) was in reality a re-expression of the old themes in the old ways. It is impossible here to do more than to point out the leading elements and to name the leading examples. These elements are, briefly stated (1) a strong partiality for subjects dealing with humble life, in country and town; (2) a whimsical, elfin kind of wit, delighting in extravagance and topsy-turviness; (3) a frank interest in the pleasures of good company and good drink. The reading of 15th- and 16th-century verse in the light of these will bring home the critical error of treating such poems as Burns's *Cottar's Saturday Night,* the *Address to the Deil* and *Scotch Drink* as entirely expressions of the later poet's personal predilection. Of the more "ethical" or "theological" mood which counts for so much in the modern estimate of Scottish literature, there is little evidence in the middle period. Even in the deliberately religious and moral work of the more academic poets this seriousness is never more oppressive than it is elsewhere at the time. If it becomes an obsession of many of the post-Reformation writers, it becomes so by the *force majeure* of special circumstances rather than in the exercise of an old habit.

Among examples of this rustic style are *Peblis to the Play* and *Christis Kirk on the Grene,* ascribed by some to James V. (*q.v.*), *Sym and his Brudir, The Wyf of Auchtirmuchty* and the *Wowing of Jok and Jynny.* The more elfin quality, familiar in Dunbar's *Ballad of Kynd Kittok* and his *Interlude of the Droichis Part,* appears in such pieces as *Gyre Carling* (the mother-witch), *King Berdok* and *Lichtounis Dreme.* The convivial verse, at its best in Dunbar's *Testament of Mr. Andrew Kennedy,* may be studied in *Quhy sould nocht Allane honorit be,* one of many eulogies of John Barleycorn before Burns's well-known piece. In the collections there are few examples of the simple *fabliau,* the best being the *Thrie Priestis of Peblis* and *The Dumb Wyf,* or of the social variety of the same as shown in *Rauf Coilȝear* and *John the Reeve.* For the latter Sir David Lyndsay remains the chief exponent. Of historical and patriotic verse there are few specimens, but some of the lyrics and love-songs, more or less mediaeval in *timbre* and form, are of importance. Of these, *Tayis Bank* and *The Murning Maiden* are perhaps the best.

Vernacular prose was, as might be expected, and especially in Scotland, late in its appearance. The main work continued to be done in Latin, and to better purpose by Hector Boece (*q.v.*), John Major (*q.v.*) and George Buchanan (*q.v.*) than by the earlier annalists Fordun (*q.v.*) and Bower (*q.v.*). It is not till the middle of the 15th century that we encounter any works seriously undertaken in the vulgar; before that time there is nothing but an occasional letter (*e.g.,* that of the earl of March to Henry IV.), a few laws, and one or two scraps in the Asloan and other mss., all of the plainest and without any effort towards style. Nor can it be said that the first works of a more deliberate character show the awakening artistic consciousness found in contemporary writings in England. The earliest books are Sir Gilbert Haye's *Buke of the Law of Arms, Buke of the Order of Knighthood* and *Government of Princes,* preserved in a single ms. at Abbotsford. The dull treatise of John of Ireland (*q.v.*) lays claim to originality of a kind. The author's confession that, being "thretty ȝeris nurist in Fraunce, and in the noble study of Paris in Latin toung," he "knew nocht the gret eloquens of Chauceir," and again that he had written another work in Latin, "the tounge that I knaw better," is valuable testimony to the difficulties in the way of a struggling Scots prose. Other preliminary efforts are the *Portuus of Nobilnes;* the *Spectakle of Luf,* translated by G. Mill (1492); and the *Schort Memoriale of the Scottis Corniklis,* an account of the reign of James II. In the early 16th century the use of the vernacular is extended, chiefly in the treatment of historical and polemical subjects, as in Murdoch Nisbet's version of Purvey, a compromise between northern and southern usage; Gau's *Richt Vay;* Bellenden's (*q.v.*) translation of Livy and *Scottish History;* the *Complaynt of Scotlande,* largely a mosaic of translation from the French; Ninian Winzet's *Tractates;* Lesley's (*q.v.*) *History of Scotland;* Knox's (*q.v.*) *History;* Buchanan's (*q.v.*) *Chamaeleon;* Lindesay of Pitscottie's (*q.v.*) *History;* and the tracts of Nicol Burne and other exiled Catholics. In these works, and especially in Knox, the language is strongly southern. The Scriptures, which had an important bearing on literary style,

were, with the exception of Nisbet's version, accepted in the southern text. It was not till the publication of Bassandyne's Bible in 1576–79 that a Scottish version was used officially. Lyndsay in the midst of passages in Scots quotes directly from the Genevan version. The *Complaynt of Scotlande* is the most striking example of "aureate" Middle Scots, the prose analogue of the verse of the "Chaucerians"; but the manner is rare in prose, even at this time. The last and most extravagant illustration of it is the *Rolment of Courtis* by Abacuck Bysset, as late as 1622.

Towards the close of the period certain verse-writers appear who, though differing from their Middle Scots predecessors, belong as much to this period as to the next. In language they are still Scottish; if they show any southern affectations, it is (all echoes of the older "aureate" style notwithstanding) the affectation of Tudor and Elizabethan English. This poetry, like that of the early half of the period, is courtly; its differences are the differences between the atmosphere of the reigns of the first and fourth Jameses and that of the sixth. When the sixth James becomes the first of England, a more thorough transformation is discernible. In the centre of this group is the king himself, poet and writer of prose; but he yields in competence to Alexander Scott (*q.v.*) and Alexander Montgomerie (*q.v.*). Their interest on the formal side is retrospective, but it is possible to find, even in the persistent reiteration of mediaeval sentiment and methods, a fresh feeling for nature and a lyrical quality of later *timbre*. With these may be named the minors, William Fowler (*q.v.*), Alexander Arbuthnot (*q.v.*) and John Rolland (*q.v.*).

The Third Period.—Strict accuracy would place the date of transition to the third period earlier than 1600 or 1603, for there is evidence in the 16th century, even outside diplomatic and official correspondence, of the intermingling of the north and south. It is, however, when James is established on his new throne that we have clear signs of the changes at work. The recital of the names of the Anglo-Scots poets will make this clear: Robert Ker, earl of Ancram, best known for his *Sonnet in Praise of a Solitary Life;* Sir David Murray of Gorthy, who wrote *The tragicall Death of Sophonisba;* Sir William Alexander (*q.v.*) afterwards earl of Stirling; William Drummond, laird of Hawthornden (*q.v.*); Sir Robert Aytoun (*q.v.*); James Grahame, marquess of Montrose; Patrick Hannay; and the covenanting Sir William Mure of Rowallan (*q.v.*). In prose there is Drummond and that strange genius Sir Thomas Urquhart (*q.v.*); a crowd of polemical writers, mostly ecclesiastics; all the historians, including Spotswood and Calderwood. Outside this transformed Scots the activities of the Latinists continued; as shown in the publication by the poet Arthur Johnston (*q.v.*) of the two volumes of *Delitiae poëtarum Scotorum huius aevi illustrium* (1637), and in the writings of John Barclay (*q.v.*) author of the *Argenis,* Sir Robert Aytoun, Thomas Dempster (*q.v.*), David Hume of Godscroft, Sir John Scot of Scotstarvet, best known for his *Staggering State,* Sir Thomas Craig, author of the *Jus Feudale* and Andrew Melville.

There is nothing in Scots to balance this English and Latin list. The play *Philotus,* a poor example in a *genre* rarely attempted in the North, is indebted to the South for more than its subject. The philological tractate *Of the Orthographie and Congruitie of the Britan Tongue* by Alexander Hume (not the verse writer) is in its language a medley; and William Lithgow had travelled too widely to retain his native speech in purity, even in his indifferent verse. Scraps may be unearthed as mediocre as the *Answer to Curat Caddel's Satyre upon the Whigs,* which attempts to revive the mere vulgarity of the Scots "flyting." The only contributions which redeem these 100 years and more from the charge of disrespect to the native muse come from the pen of the Sempills.

We are attracted to Beltrees and his kinsmen less by their craftsmanship than by the fact that they supplied the leaders of the vernacular revival of the 18th century with many subjects and verse-models, and that by their treatment of these subjects and models, based on the practice of an earlier day, they complete the evidence of the continuity of the domestic popular type of Scots verse. In the 18th century the literary union of the North and South is complete. The Scot, whatever dialectal habits marked his speech, wrote the English of Englishmen. The story of this later expression is part of the story of English literature: to it we leave James Thomson, Adam Smith, David Hume, James Boswell and Sir Walter Scott. In the vernacular revival begun by Allan Ramsay, continued by Fergusson and completed by Burns, these later Scots restored a tradition, not so much because it was national, as because it directly helped the general protest against the artificiality of the century. Yet even they did not abjure the "southern manner," and their work in it is a matter of some critical significance, whatever may be said of its inferiority in craftsmanship.

IN GAELIC

It is not until after the Forty-five that we find any great manifestation of originality in the literature of the Scottish Highlands. The reasons for this are not far to seek. Scotch Gaelic was from the outset seriously handicapped by the great activity of the professional literary class in Ireland. We may say that down to the beginning of the 18th century the literary language of the Highlands was the Gaelic of Ireland. During the dark days of the penal laws and with the extinction of the men of letters and their patrons in Ireland, an opportunity was given to the native Scottish muse to develop her powers. Further, after Culloden the causes of the clan feuds and animosities of the past were removed. The Highlands, perhaps for the first time in history, formed a compact whole and settled down to peace and quietude. A remarkable outburst of literary activity ensued, and the latter half of the 18th century is the period which Scottish writers love to call the golden age of Gaelic poetry. But before we attempt to deal with this period in detail, we must examine the scanty literary products of Gaelic Scotland prior to the 18th century.

Highland Mss.—The earliest document containing Gaelic matter which Scotland can claim is the *Book of Deer,* now preserved in the Cambridge university library. This ms. contains portions of the Gospels in Latin written in an Irish hand with illuminations of the well-known Irish type. Inserted in the margins and blank spaces are later notes and memoranda partly in Latin, partly in Gaelic. The Gaelic entries were probably made between 1000 and 1150. They relate to grants of land and other privileges made from time to time to the monastery of Deer (Aberdeenshire). The language of these entries shows a striking departure from the traditional orthography employed in contemporary Irish documents. The Advocates' library in Edinburgh contains a number of mss. probably written in Scotland between 1400 and 1600 but with one exception the language is Irish.

The solitary exception just mentioned is the *Book of the Dean of Lismore.* The pieces contained in this volume are written in the crabbed current Roman hand of the period, and the orthography is phonetic, both of which facts render the deciphering of this valuable ms. difficult. The contents are almost entirely verse compositions collected by Sir James Macgregor, dean of Lismore in Argyllshire, and his brother Duncan, between the years 1512 and 1526. A disproportionate amount of space is allotted to the compositions of well-known Irish bards, but native bards are also represented. We can mention Allan MacRorie, Gillie Calum Mac an Ollav, John of Knoydart, Finlay MacNab, and Duncan Macgregor, the transcriber of the greater part of the volume. A few other poems are by Scottish authors such as Campbell, Knight of Glenorchy (d. 1513), the earl of Argyll and Countess Isabella. A number consist of satires on women. These Scottish writers are still under the influence of Irish metric but frequently use the freer forms of the old metres.

Among the pieces which represent the Scottish vernacular of the day are the *Ossianic Ballads.* These, 28 in number, extend to upwards of 2,500 lines, and form by far the most important part of the collection. Nine of the poems are directly attributed to Ossian, two to Ferghus File, one to Caoilte Mac Ronan, and one to Conall Cearnach, whilst others are ascribed to Allan MacRorie, Gillie Calum Mac an Ollav and Caoch O'Cluain, who

are otherwise unknown. Thomas MacLauchlan published the text of the Ossianic ballads with modern Gaelic and English renderings in 1862. In the same volume W. F. Skene gave a useful description of the ms. and its contents. Alexander Cameron published in his *Reliquiae Celticae,* vol. i., a selection partly coinciding with MacLauchlan's.

Between the Book of the Dean and the Forty-five we find another great gap, which is only bridged over by a collection which presents many points of resemblance to Macgregor's compilation. The *Book of Fernaig,* also written in a kind of phonetic script, was compiled by Duncan Macrae of Inverinate between 1688 and 1693. The ms. contains about 4,200 lines of verse of different dates and by different authors. The contents of the collection are mainly political and religious, with a few poems which are termed didactic. In State politics the authors are Jacobite, and in church politics Episcopalian. The Ossianic literature is represented by 36 lines. There are a number of poems by 16th-century writers, among whom is Bishop Carsewell. The text of the *Book of Fernaig* is printed in its entirety with a transcription in standard orthography, by M. Macfarlane, 1923.

Two other Highland mss. remain to be noticed. These are the *Red* and *Black Books of Clanranald,* which are largely taken up with the histories of the families of Macdonald and with the achievements of Montrose, written in the ordinary Irish of the period by the Macvurichs, hereditary bards to the Clanranald chiefs. During the Ossianic controversy the *Red Book of Clanranald* was supposed to contain the originals of much of Macpherson's famous work; but, on the book coming into the hands of the enthusiastic Gaels of the closing years of the 18th century, and on its contents being examined and found wanting, the ms. was tampered with.

Mary Macleod.—Mackenzie's *Beauties of Gaelic Poetry* contains poems written by a number of writers who flourished towards the end of the 17th century and at the beginning of the 18th. Among them are Mary Macleod, John Macdonald (Iain Lom), Iain Dubh MacIain 'Ic. Ailein (b. *c.* 1665), the Aosdan Matheson (one of his poems was rendered in English by Sir Walter Scott under the title of "Farewell to Mackenzie, High Chief of Kintail"), Roderick Morrison and John Mackay of Gairloch, but we can here only notice the first two. The famous Mary Macleod, better known as Mairi Nighean Alastair Ruaidh (*c.* 1588–1693), was family bard to Sir Norman Macleod of Bernera, and later to John "Breac" Macleod of Macleod, in honour of whom most of her poems were composed. Her pieces, all of them composed after 1660, are composed in the modern Irish metres with the characteristic vowel rhymes of the accented syllables. Mary Macleod's best-known pieces comprise a dirge on the drowning of Iain Garbh (Mac'Ille Chalum) in the Minch, a song "An Talla 'm bu ghnath le MacLeoid," and an ode to Sir Norman Macleod of Bernera, produced during her exile in Mull, which begins "S mi'm shuidhe air an tulaich." For the details of her career, the reader may be referred to the *Transactions of the Gaelic Society of Inverness,* vol. xxii. pp. 43–66. A number of poems belonging to this period have been published in *The Macdonald Collection of Gaelic Poetry* (1911).

John Macdonald, better known as Iain Lom (d. *c.* 1710), was a vigorous political poet whose verses exercised an extraordinary influence during his lifetime. His best-known poems are *Mort na Ceapach,* on the murder of the heir of Keppoch, and a piece on the battle of Inverlochay (1645). However great the inspiration of Mary Macleod and Iain Lom, they were after all but political or family bards. In succession to them there arose a small band of men with loftier thoughts, a wider outlook and greater art. The literature of the Scottish Highlands culminates in the names of Alexander Macdonald, Duncan Bàn MacIntyre and Dugald Buchanan.

Alexander Macdonald.—Alexander Macdonald, commonly called Alasdair MacMhaighstir Alasdair (b. *c.* 1700), was the son of an Episcopalian clergyman in Moidart. He was sent to Glasgow university, but an imprudent marriage caused him to abandon his studies, and about 1729 he received an appointment as a Presbyterian teacher in his native district. About 1740 he was invited to compile a Gaelic vocabulary, which was published in 1741. Macdonald has thus the double distinction of being the author of the first book printed in Scotch Gaelic and of being the father of Highland lexicography. After the landing of the Pretender he was given the rank of captain, but rendered greater services to the Jacobite cause with his stirring poems than with the sword. In 1751 he visited Edinburgh and brought out a collection of his poetry, which was the first original work printed in Scotch Gaelic, and was therefore entitled *Ais-eiridh na Seann Chanain Albannaich* (Resurrection of the Ancient Scottish Tongue). Macdonald's compositions naturally fall into three groups—love-songs, descriptive poems and patriotic and Jacobite poems. In his love-songs and descriptive poems Macdonald struck an entirely new note in Gaelic literature. His *Moladh Mòraig* and *Cuachag an Fhàsaich* (also called *A'Bhanarach Dhonn*) are his best-known love-songs. But he is distinctly at his best in the descriptive poems.

His verse is always musical, and his skilful use of epithet, often very lavishly strewn, enables him to express with marvellous effect the various aspects of nature in her gentler and sterner moods alike. His masterpiece, the *Birlinn of Clanranald,* which is at the same time, apart from Ossianic ballads, the longest poem in the language, describes a voyage from South Uist to Carrickfergus. Here Macdonald excels in describing the movement of the ship and the fury of the storm. In *Allt an t-Siucair* (The Sugar Brook) we are given an exquisite picture of a beautiful scene in the country on a summer morning. Other similar poems full of melody and colour are *Failte na Mòr-thir* (Hail to the Mainland), *Oran an t-Samhraidh* (Ode to Summer), and *Oran an Gheamhraidh* (Ode to Winter). Among the Jacobite poems we may mention *Oran nam Fineachan Gaelach* (The Song of the Clans), *Brosnachadh nam Fineachan Gaidhealach* (A Call to the Highland Clans), and various songs to the prince. But incomparably the finest of all is *Oran Luaighe no Fucaidh* (Waulking Song). Here the prince is addressed as a young girl with flowing locks of yellow hair on her shoulders, and called Morag. She had gone away over the seas, and the poet invokes her to return with a party of maidens (*i.e.,* soldiers) to dress the red cloth, in other words, to beat the English red-coats. Macdonald's works have gone through several editions, the last of which is dated 1924.

Duncan Bàn.—The only poet of nature who can claim to rival Macdonald is a man of a totally different stamp. Duncan Bàn MacIntyre (Donnachadh Bàn, 1724–1812) was born of poor parents in Glenorchy, and never learned to read and write or to speak English. He was present on the English side at the battle of Falkirk, on which he wrote an ode, and shortly afterwards he was appointed gamekeeper to the earl of Breadalbane in Coire Cheathaich and Ben Dorain, where he lived for many years until he accepted a similar appointment from the duke of Argyll in Buachaill-Eite. In addition to his poems descriptive of nature MacIntyre composed a number of Jacobite martial songs, songs of love and sentiment, and comic and satiric pieces. The poem *Màiri bhàn òg* addressed to his wife is, on account of its grace and delicate sentiment, generally held to be the finest love-song in the language. But it is above all as the poet of ben and corrie that MacIntyre is remembered. He has been called the Burns of the Highlands, but the bitterness and intellectual power of the Ayrshire poet are absent in MacIntyre.

Duncan Bàn describes fondly and tenderly the glories of his native mountains as only one can who spends his life in daily communion with them. His two great compositions are styled *Ben Dòrain* and *Coire Cheathaich.* The former, which might be called the "Song of the Deer," has been well done into English by J. S. Blackie. *Coire Cheathaich* (The Misty Corrie), a much shorter poem than *Ben Dòrain,* gives a loving description of all the prominent features in the landscape—the flowers, the bushes, the stones, the hillocks with the birds and game, and the whirling eddies with the glistening salmon. MacIntyre's works, first published in 1768, went through three editions in his lifetime. The most recent edition, by G. Calder, appeared in 1912.

From Duncan Bàn we pass on to consider the compositions of two men who hailed from the outlying parts of Gaeldom, Robert

Mackay, or, as he is generally called, Rob Donn (1714–78), was a native of Strathmore, Sutherlandshire. He left behind a large number of poems which may be roughly classified as elegiac, love, and satiric poems. His best-known elegy is "The Death-Song of Hugh." Having just heard of the death of Pelham, the prime minister, Mackay finds a poor friend of his dying alone amid squalor in the heart of the mountains. In a poem composed on the spot the poet contrasts the positions of the two men and reflects on the vanity of human existence. Among his love-poems the "Shieling Song" is deservedly famous. But it was above all as a satirist that Mackay excelled during his lifetime. Indeed he seems to have had the sharpest tongue of all the Highland bards, but many of Rob Donn's compositions have lost their point, and opinions have been greatly divided as to his merits as a poet. His collected poems were first published in 1829, a second edition appeared in 1871, and in 1899 two new editions were issued simultaneously. Another satirical poet who enjoyed a great reputation in his own day was John MacCodrum, a native of North Uist and a contemporary of the men just mentioned. A number of his compositions are addressed to his patrons, but one delightful poem entitled *Smeòrach Chlann-Domhnuill* (The Mavis of Clan Donald) describes in verses full of melody the beauties of his beloved island home.

Dugald Buchanan.—In the lyrical outburst which followed the Forty-five religious poetry is well represented. The first religious poem to be printed in Scotch Gaelic was a long hymn by David Mackellar, published in 1752. But incomparably the greatest writer of hymns and sacred poems is Dugald Buchanan (1716–68). Buchanan was born in Strathyre in Perthshire and was the son of a miller. He received a desultory kind of education and tried his hand at various trades. He was selected to assist Stewart of Killin in preparing the first Highland version of the New Testament for the Society for Propagating Christian Knowledge (published 1767), and at the same time he issued an edition of his own poems. Of all Gaelic books this has been far and away the most popular, having gone through no less than 40 editions, the last in 1913. Buchanan seems to have been very susceptible to religious influences, and the stern Puritan doctrines of retribution and eternal damnation preached around him so worked on his mind that from his 9th to his 26th year he was a prey to that mental anguish so eloquently described by Bunyan. The awful visions which presented themselves to his vivid imagination find expression in his poems. In the "Day of Judgment," a poem of about 120 stanzas, we are given a vivid delineation of the crack of doom as the archangel sounds the last trump. But Buchanan's masterpiece is admittedly "The Skull," the subject of which, it seems certain, was suggested by Shakespeare. The poet seated by a grave espies a skull. He takes it up and muses on its history. This poem in 44 stanzas concludes with a picture of the torments of hell and the glories of heaven.

Macpherson's "Ossian."—The writers whom we have been discussing are practically unknown save to those who are able to read them in the original. Now we turn our attention to a man who plays a prominent part in the history of European literature. Though the precise origin of the Fenian cycle may remain a moot point to all time, the interest taken in Celtic studies since the middle of the 19th century in Ireland and Scotland and elsewhere has accumulated a body of evidence which has settled for all time the dispute as to the authenticity of Macpherson's *Ossian.* James Macpherson (1736–96), a native of Kingussie, showed a turn for versification whilst yet a student at college. Whilst acting as tutor at Moffat he was asked by John Home as to the existence of ancient Gaelic literature in the Highlands. After some pressing Macpherson undertook to translate some of the more striking poems, and submitted to Home a rendering of "The Death of Oscar." Blair, Ferguson and Robertson, the foremost men in the Edinburgh literary circles of the day, were enthusiastic, and at their instance Macpherson published anonymously in 1760 his *Fragments of Ancient Poetry, collected in the Highlands of Scotland and translated from the Gaelic or Erse Language,* containing 15 translations, preceded by a preface from the pen of Blair. In the preface it was stated that an epic of considerable length existed in Gaelic, and that, given sufficient encouragement, the author of the versions would undertake to recover and translate it. A subscription was raised and after a tour of exploration, on which he was accompanied by two or three competent Gaelic scholars, Macpherson published in London in 1762 his epic *Fingal* with 15 other smaller poems. In the following year a still larger epic in eight books appeared with the title of *Temora.*

The authenticity of Macpherson's translations was soon impugned by Dr. Johnson, Hume and Malcolm Laing, and the author was urged by his friends to publish the originals. Macpherson at different times seems to have had some intention of publishing the Gaelic of his *Ossian,* but he was naturally deterred by the feeling that his knowledge of Gaelic was becoming shakier with his continued absence from the Highlands. At any rate he left behind a quantity of Gaelic matter in ms. which was ultimately published by the Highland Society of London in 1807. This ms., however, was revised and transcribed by Ross and afterwards destroyed, so that we are ignorant of its nature. Macpherson's claims still found ardent advocates, such as Clark, in the '70s, but the question was finally disposed of in papers by Alexander Macbain (1885) and L. C. Stern (1895). We can here only summarize briefly the main lines of argument. (1) Macpherson's *Ossian* is full of reminiscences of Homer, Milton and the Hebrew prophets. (2) He confuses the Ulster and the Fenian heroic cycles in unpardonable fashion. (3) The Gaelic text of 1807 only represents one-half of the English versions (11 poems out of 22 poems). Some Gaelic fragments from different pens appeared prior to 1807, but these differ considerably from the "official" version. (4) In the Gaelic text of 1807 the version of the passage from *Temora* is quite different from that published in 1763. (5) Macpherson's Gaelic is full of offences against idiom and unnaturally strained language. (6) The names Morven and Selma are entirely of his own invention. (*See* also MACPHERSON, JAMES.)

Later Poets.—The men we have dealt with above created a kind of tradition which others have attempted to carry on. Ewen Maclachlan (1775–1822), the first transcriber of the Dean's Book, translated the greater part of seven books of Homer's *Iliad* into Gaelic "verse," and he also had a large share in the compilation of the Gaelic-English part of the Highland Society's *Dictionary.* His poems, published in 1816, consist of poems of nature, e.g., *Dàin nan Aimsirean, Dàn mu Chonaltradh, Smeòrach Chloinn-Lachuinn,* and of a well-known love-song, the *Ealaidh Ghaoil.* William Ross (1762–90), a schoolmaster at Gairloch, composed, among other popular poems, *Feasgar Luain* and *Moladh na h-Òighe Gaelich.* Another exquisite song *Cuachag nan Craobh,* is usually attributed to this poet, but it seems to go back to the beginning of the 18th century. A fifth edition of Ross's poems appeared in 1902. The most popular writer of sacred poems after Buchanan is undoubtedly Peter Grant, a Baptist minister in Strathspey, whose *Dàin Spioradail* (first published in 1809) reached a 20th edition in 1904. Two other well-known hymn-writers spent their lives in Nova Scotia—James Macgregor (1759–1830), and John Maclean, a native of Tiree. The compositions of the latter have been published under the title *Clarsach na Coille* (Glasgow, 1881). But John Morrison (1790–1852), the poet-blacksmith of Rodel, Harris, is the most worthy of the name of successor to Buchanan. His works have been carefully edited in two volumes by George Henderson (2nd ed. 1896). Two of his most characteristic poems are *An Iondruinn* and *Tha luin' òg agus seann duin' agam.* William Livingston or MacOhunleibhe (1808–70) was a native of Islay. He was ever a fierce Anglophobe, and did his best to make up for the deficiencies of his early training. His poems, which have been at least twice published (1858, 1882), are powerful in the expression of ruthless fierceness and tearful sorrow. Livingston's contemporary, Evan Maccoll (1808–98), the son of a small farmer on Lochfyneside, is remembered for his *Bàs Màiri* and *Duanag Ghaoil.* We can do no more than mention the names of John Maclachlan of Rahoy (1804–74), James Munro (1794–1870), well known as a grammarian, Dugald Macphail (b. 1818), and Neil Macleod (b. 1843), author of a popular collection *Clarsach an Doire* (1st ed., 1883; 3rd ed., 1904). Neil Macleod

is also the writer of the popular song *An Gleann's an robh mi òg.* *The Poetry of Badenoch* (1906) may be mentioned here. It is natural to compare the state of affairs at the beginning of the 20th century with that obtaining in 1800. In the dawn of the 19th century every district in the Highlands had its native poet, whilst a century later not a single Gaelic bard of known reputation existed anywhere within its borders. It is only too evident that the new writers prefer English to Gaelic as a medium of literature, partly because they know it better, but also because in it they appeal to a far wider public.

Prose Writers.—It will have been observed that we have said nothing about prose works written in Gaelic. The first printed work is the translation of Knox's *Liturgy* by Bishop Carsewell, published in 1567 (reprinted in 1873). Calvin's Catechism is said to have been issued in 1631. The Psalms and Shorter Catechism appeared in 1659, while two other psalters saw the light before the end of the century, one by Kirke (1684), the other issued by the Synod of Argyll (1694). The language of all these publications is, however, Irish. Apart from reprints of the catechism and psalter, the only other Gaelic matter which appeared in print before 1750 were Kirke's Irish version of the Bible in Roman type with a vocabulary (1690), and the *Vocabulary* by Alexander Macdonald (1741). But from the middle of the 18th century translations of the works of English religious writers streamed from the various presses. Alleine, Baxter, Boston, Bunyan, Doddridge and Jonathan Edwards were all prime favourites, and their works have gone through many editions. There are also translations of parts of *The Arabian Nights* and of *Robinson Crusoe.* James Stewart of Killin's version of the New Testament, published by the Society for Propagating Christian Knowledge, was followed by a translation of the Old Testament (1783–1801), the work of John Stewart of Luss and John Smith of Campbeltown. The whole Gaelic Bible saw the light in 1807. But the revision of 1826 is regarded as standard. Of original prose works we can mention two. The one is a *History of the Forty-five* (*Eachdraidh a' Phrionnsa, no Bliadhna Thearlaich*), published in 1845 by John Mackenzie, the compiler of the *Beauties of Gaelic Poetry* (1806–48). A second edition of this book appeared in 1906. The other is the more famous *Caraid nan Gaedheal,* by Norman Macleod (new ed. 1899). This volume consists mainly of a number of dialogues dealing with various departments of Highland life, which were originally contributed to various magazines from 1829 to 1848. In recent years there have been two or three attempts at fiction and drama, but the achievement has not been noteworthy.

In conclusion we must take notice of the more important collections of folklore. Gaelic, like Irish, is extraordinarily rich in proverbs. A collection of Gaelic proverbs, published in 1785 by Donald Macintosh, was supplemented and enlarged in 1881 by Alexander Nicolson, whose book contains no fewer than 3,900 short sayings. A large collection of Gaelic folk-tales was published by J. F. Campbell under the title of *Popular Tales of the West Highlands* (4 vols., 1862). Alexander Carmichael published a version of the *Táin Bó Cualnge,* called *Toirioc na Táine,* which he collected in South Uist (*Transactions of the Gaelic Society of Inverness,* ii. 25–42), also the story of Deirdre and the sons of Uisneach in prose taken down in Barra (*ib.* xiii. 241–257). Five volumes of popular stories, collected by J. G. Campbell, D. MacInnes, J. Macdougall and Lord Archibald Campbell, have been published (1889–95) by Nutt under the title *Waifs and Strays of Celtic Tradition.* Seven ballads dealing with the Ulster cycle were collected and printed by Hector Maclean under the title *Ultonian Hero-ballads* (Glasgow, 1892). Macpherson gave a fillip to collectors of Ossianic lore, and a number of mss. going back to his time are deposited in the Advocates' library at Edinburgh. J. F. Campbell spent 12 years searching for variants, and his results were published in his *Leabhar na Feinne* (1872). The Edinburgh mss. were transcribed by Alexander Cameron, and published after his death by Alexander Macbain and John Kennedy in his *Reliquiae Celticae.* Finally the charms and incantations of the Highlands have been collected and published by Alexander Carmichael in two volumes under the title *Carmina Gadelica* (1900).

Bibliography.—The standard work is Magnus Maclean, *The Literature of the Highlands* (1904); *see* also various chapters in the same writer's *Literature of the Celts* (1902); L. C. SCOTTSBLUFF, a rapidly growing city of Scotts Bluff county, Nebraska, U.S.A., on the North Platte river, 20 m. from the western boundary of the State, at an altitude of 3,880 ft.; on Federal highway 26, and served by the Burlington (railway) Route. The population was 6,912 in 1920 (83% native white) and was 8,465 in 1930 by the Federal census. It is the metropolis of a fertile irrigated region, and has one of the largest beet-sugar factories in the country. Near by are an experiment station of the U.S. Department of Agriculture and the Scotts Bluff National Monument (1,894 ac., set aside in 1919), a tract of historic and scientific interest, through which passed many of the trails used by the pioneers. Scottsbluff was founded and incorporated as a village in 1901, and was chartered as a city in 1911.

SCOUT, a soldier sent out to watch the enemy and bring information of his numbers, movements, whereabouts, etc. For boy scouts *see* Boy Scouts.

SCRANTON, a city of north-eastern Pennsylvania, U.S.A., the county seat of Lackawanna county; 134 m. W.N.W. of New York city, on the Lackawanna river and Federal highways 6, 11 and 611. It is served by the Central of New Jersey, the Delaware and Hudson, the Erie, the Lackawanna, and the New York, Ontario and Western railways, two inter-urban electric lines, and several motor-bus lines. Pop. (1920) 137,783 (21% foreign-born white, over half from Russia, Lithuania, Poland, Austria, Italy and Ireland); 1930 Federal census 143,433. More than half a million people live within a radius of 15 m.

Scranton is the metropolis of the great anthracite region of north-eastern Pennsylvania, which contains nearly all the anthracite deposits of the United States and produces in a normal year over 75,000,000 gross tons. It occupies 20·5 sq.m. in the Lackawanna valley, at an elevation ranging from 800 to 1,800 ft. above sea-level, and is surrounded by a region of great natural beauty (mountains, lakes and streams). There are several pleasure resorts and sanatoria in the immediate vicinity. The business section of the city is compactly built up with substantial structures, largely of modern type. The 12 public parks cover 160 ac., and the municipal recreation bureau provides facilities for a great variety of sports and amusements at all seasons of the year. In Nay Aug park are the picturesque falls of Roaring Brook (which crosses the city to empty into the Lackawanna river), a zoological garden, the Everhart museum of natural history (which contains a fine exhibit of birds and reptiles and the Hollister collection of Indian relics) and a small-scale mine, in a 5 ft. vein of coal, constructed so as to demonstrate the actual methods of mining anthracite.

The educational institutions of the city include 50 public and 12 parochial schools, several private schools and business colleges, a conservatory of music, St. Thomas college for men (Roman Catholic; 1888), Marywood College for Women (Roman Catholic; 1917), extension centres of the University of Pennsylvania and Pennsylvania State college, and the International Correspondence Schools and Woman's institute. In the adjoining borough of Dunmore is the Pennsylvania State Oral School for the Deaf (1882). The International Correspondence Schools now occupy two of the largest and finest buildings in the city.

There are about 140 churches in the city, representing 28 or 30 denominations, including Greek Catholic, Reformed Polish and Russian Orthodox.

JAPANESE "WAVE SCREEN" OF THE 17TH CENTURY, PAINTED BY OGATA KORIN

This screen, with its design of waves dashed on a gold ground between stretches of smooth water, is one of the most prized productions of Korin. It is characteristic of the artist in its combination of simplicity with daring composition. Korin painted folding screens, fans and lacquers of great beauty. The "Wave Screen" is signed "Hokkyō Kōrin," accompanied by one of his seals "Dōsū"

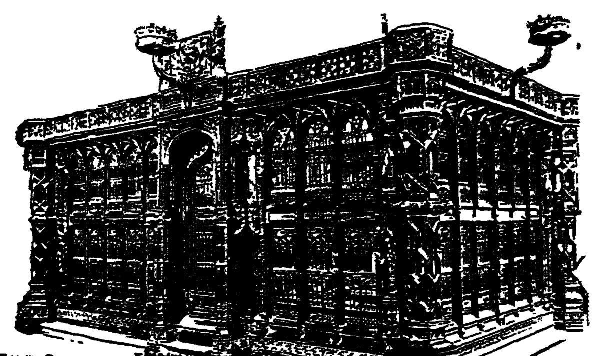
Scranton has a large retail, wholesale and jobbing trade, and its manufacturing industries have increased in importance and diversity until the wage-earners in factories outnumber the coal miners. Anthracite-mining is still, however, the dominating industry, engaging a fifth of all the persons employed in gainful occupations in 1920. Much of the city's area is undermined. In some sections, surface subsidence and occasionally a cave-in give visible evidence of the work in progress underground, and whenever a long suspension or strike occurs (as in 1902, 1912, 1922 and 1925) the economic fabric of the city is seriously affected. Silk manufacturing ranks next to the anthracite industry in importance, with two score mills in Scranton and Dunmore, employing 4,500 persons and using about a third of all the raw silk imported into the country. Building permits for the ten years 1918–27 represented values aggregating $40,369,406. The output of the city's factories in 1927 was valued at $55,704,206.

Permanent settlement on the site of Scranton dates from 1788. A grist-mill, a sawmill and a charcoal iron-furnace were built in the next few years, but there was little further development until 1840, when the Lackawanna Iron Company bought a large tract (the greater part of the city's present territory) for $8,000, and began the manufacture of iron, getting ore from the deposits in the near-by hills, and using for the first time the anthracite hot blast. Initial difficulties were overcome largely through the persistent efforts of George Whitefield Scranton (1811–61), aided by his brother Selden and their cousin, Joseph Hand Scranton. By 1850 a rolling mill, a nail factory and a steel-rail works were in operation, and transportation facilities had been provided. Scranton was incorporated as a borough in 1853, as a city in 1866. Before the iron ore was exhausted, the anthracite industry was well established. Skilled miners were attracted from England, Wales and Germany, whose descendants are an important element in the present population, though Poles and Russians now predominate among the foreign-born miners. The development of the silk industry and other manufactures has taken place largely since 1900. The population of the city was 9,223 in 1860; 45,850 in 1880; and 102,026 in 1900. In the decade following the World War bank deposits, postal receipts, and the number of telephones in use (indices in a general way of the volume of business) all increased about 100%.

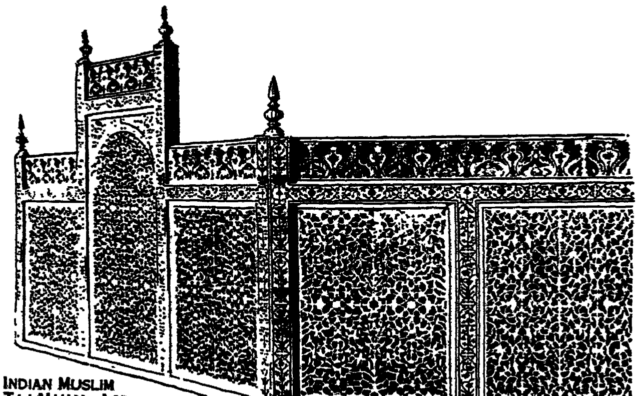
SCREAMER (*Palamedea cornuta*), a bird inhabiting Guiana and the Amazon valley. About the size of a turkey, it is remarkable for the slender "horn" more than 3in. long, on its crown, the two sharp spurs on each wing, and its long toes. Its plumage is mainly greyish-black above with some white and reddish-brown, while the lower parts are white. Related to this bird is *Chauna chavaria*, the "Crested Screamer," a name first bestowed on the Seriema (*q.v.*). This bird inhabits the lagoons and swamps of Paraguay and Southern Brazil, where it is called "Chajá" and is smaller than the preceding, wanting its "horn," but having a crest of feathers; the plumage is mainly grey. Its nest is of dry rushes, having its foundation in the water, and contains six eggs, which are white tinged with buff. The young are covered with yellowish-brown down. A singular habit of this bird is that of soaring in circles at an immense altitude in flocks uttering at intervals their far-reaching and melodious cry. They also sing on the ground (*see* W. H. Hudson, *Naturalist in La Plata,* who also records hearing over a hundred thousand burst into song together). The young are often reared by the people to defend their poultry, a duty which is faithfully and, owing to its spurs, successfully discharged. Another curious property of this bird is a layer of air-cells between the skin and the muscles, so that on the body being pressed a crackling is heard. In Central America the darker *C. derbiana* occurs. It is a smaller bird than the others, with slate-gray plumage and white throat.

The *Palamedeidae* are by many authors placed in a distinct order, *Palamedeiformes*, near the *Anseres*. (*See* ORNITHOLOGY.)

SCREEN, in architecture, any one of various types of subdivisions between adjacent portions of the same open space. Thus the colonnades under the great arches in the tepidaria of certain Roman baths formed screens, mainly decorative, between the central space and alcoves or recesses at the ends and sides. The term is especially used in ecclesiastical architecture for the railings, barriers or other dividing elements between chapels and the aisle or nave or around the choir. Chapel screens were usually open and consisted of an arcade of tracery or of a metal grille. Choir screens, on the other hand, were, in north and west Europe, largely solid, although relatively small in height, so that the services held behind them could be heard by those in the nave although the clergy and choir remained unseen. Of choir screens of this type, those of the cathedrals of Amiens and Chartres, both of the 15th century, are especially rich; in England, that of York (1475–1505), Canterbury (15th century) and Exeter (first half 14th century) are noteworthy. In Italy the tradition of the early Christian bemas, ambones and low chancel railings dictated an entirely different type of screen; the chancel front of S. Miniato, near Florence, with its elaborately inlaid marble parapet of the late 11th and early 12th century is typical. With the coming of the Renaissance even this amount of separation was abandoned and in the great Renaissance churches of Italy the use of the screen as a separation for the choir disappears. In Spain the high development of ironwork led to the extensive use of that material for both choir and chapel screens. This iron screen work, termed *rejeria* (*q.v.*), constitutes one of the most glorious adornments of the Spanish churches. (*See* JUBÉ; STALL.) (T. F. H.)



TOMB SCREEN FROM HENRY 7TH CHAPEL WESTMINSTER ABBEY EARLY 16TH CENTURY



INDIAN MUSLIM TAJ MAHAL, AGRA TOMB SCREEN 17TH CENTURY

SCREENS OF CHINA AND JAPAN

Because of their fragile nature, no screens of great antiquity have survived, but references to them are not wanting in ancient literature. Folding screens were known in China as early as the 2nd century B.C., at which period glass or mica panellings for them are noted as of much value, their transparent nature affording both enjoyment of an outdoor view and shelter from the elements. Then, in the century preceding the Christian era, screens carved and inlaid with jade and other precious materials seem to have been produced. Already in this early period the art of painting screens was practised, for it is recorded that

"Figures of Exemplary Women," illustrating the good or evil effects from right or wrong-doing were depicted on a screen. The Chinese artist Ts'ao Pu-hsing (3rd century) having dropped ink upon a screen while painting, turned it into a fly which Sun Ch'üan (A.D. 181–252) tried to brush away. Shih Hu (3rd century) made a folding screen covered with silk and painted with hermits, birds and animals, to which he added a long inscription. Chang Mo (4th century) depicted on screens the Buddhist saint, Vimalakirti, and a scene entitled "Beating Newly-woven Silk." In passing, mention may be made of a 14-fold screen in the scroll attributed to Ku K'ai-chih (4th century), owned by the British Museum, confirming the accuracy of contemporary accounts that screens consisted of numerous leaves, sometimes as many as 40. In the 5th century, Lu T'an-wei painted a lion and Fang Huai-chên the "Paragons of Filial Piety." Landscapes were not unknown in these early centuries as themes for screens, for they are referred to in old poems and other writings. Screens of tapestry, of embroidery, of crystal and of lacquer are also recorded in contemporary literature. Moreover, fine calligraphy inscribing moral teachings or auspicious sentiments was executed on screens from the 5th century, if not earlier. It is said that Fang Hsüang-ling (A.D. 578–648) collected precepts from all sources and inscribed them on screens which he distributed among his children as reminders of proper conduct.

The T'ang Period.—In the luxurious days of the T'ang dynasty (618–906), screens were in constant demand to adorn palaces and mansions. Those which were bedecked with gold and silver, pearl and tortoise shell, or those of fine textiles woven or dyed, bearing characteristic patterns, must have imparted great splendour to the habitations of rulers and princes. Horses sent from foreign tribes to the imperial stables furnished themes for screens, and a fabulous animal called *mo* which is supposed to eat bad dreams was deemed an appropriate subject for boudoir screens. Then, too, such noted painters as Pien Luan (who treated flowers and birds), Chang Tsao (pines and rocks), and Chou Fang (court beauties), and such accomplished calligraphers as Li Yang-ping and Chang Hsü all decorated screens. Some emperors had about them screens setting forth worthy and moral deeds performed by men of the past, in order that they themselves, as well as their subjects, might derive benefit from these constant reminders.

But for actual examples of T'ang art on screens we have to turn to Japan where, in the Imperial repository called the Shōsōin, at Nara, are still preserved relics of the art of that golden epoch. This treasure-house contains principally the personal belongings of the Emperor Shōmu, which were given to the Great Buddha of the Tōdaiji by the Empress Kōmyō, in 756. The list of donations mentions, among other objects, 100 screens, to which several more were added, at three different times, between the years 756 and 758. Among this large number of screens were examples of Chinese, Korean or Japanese origin which included paintings of landscapes, palaces, figures and flowers; others of batik and of block-resist dyeing, figuring birds, animals and flowers; and, in addition, some screens on which Chinese ideographs formed the chief decoration. Of these 100 odd screens but few remain at present, in whole or in part, among them no painted screens. Nevertheless, the pictorial accomplishments of the 8th century may still be seen in this collection in a six-fold screen, in each leaf of which is shown a figure of a woman standing under a tree. The subject was originally worked in birds' feathers which have disappeared, leaving only the preliminary drawings. Despite the sketchy nature of the drawings of the figures, trees and rocks, one may detect the mature brush-strokes, the importance of which is so much emphasized in the art of painting in the Far East. The screen is probably Japanese, yet its conception and execution are based upon contemporary Chinese patterns. There are also two six-fold screens in this imperial collection, the chief decorative features of which are Chinese inscriptions in large characters. One (Plate III., fig. 1) contains a precept for a ruler, consisting of 48 Chinese ideographs, each written twice, once in the *chuan* ("seal") style and once in the *hsing* ("running") style. The backgrounds are of silk dyed in green and red—alternating in the six panels—bearing designs of conventionalized clouds, birds, animals, trees, plants and rocks, all in white reserve. The screen is very likely Chinese, one of many gifts sent to the Japanese court from China, although it is said that at one time there was discovered upon it a Japanese date corresponding to the year 751—a fact lacking substantiation. In the Orient, to use writing on a large scale for a decorative scheme is no less frequent than to employ a picture for the purpose. Indeed, good calligraphy (*q.v.*) is considered an art of as great importance as good painting, both being the result of brush-work and both presenting images of mental conception.

An example of the pictorial art of the T'ang as reflected in the art of Japan may be seen in a screen (Plate III., fig. 2), preserved in the Buddhist monastery of Tōji in Kyoto. It treats a landscape in polychrome: among trees surrounded by hills and water is a rustic abode within which sits a hermit who is being visited by nobles with their servants. According to an old tradition, the screen was one of the treasures brought back by Kōbō Daishi from China in 806. However, some authorities now regard the painting as a Japanese production of the 11th century, based upon a T'ang original. For, despite its Chinese design, in it are discernible certain technical peculiarities of the early Yamato-é (literally "Japanese picture") style which was developed during the Fujiwara period (900–1189) and is characterized by over-refinement of drawings. Such a landscape screen was used in the baptismal rituals of esoteric Buddhism which required a pictorial representation of a mountain scene in lieu of the natural setting in which the religious service took place in old India. No screens of a secular nature dating from the Fujiwara period are now extant, but literary sources disclose the thousands of screens painted for the use of the Japanese court and for the mansions of nobles. As in the preceding epoch, the need for screens was pressing, because of the peculiar style of the architecture of those days—wide openings on the sides of a building which were closed by wooden doors at night but which during the day needed screening arrangements. Regular and occasional State functions also required special screens appropriate to the events. That a large number of screens was produced may be gathered from the record that Yoshichika (11th century) painted 200 screens on Lord Yoshimichi's order. A story is told about Hirotaka (10th century) who delineated a scene of hell containing a demon who proved so lifelike as to convince the artist that the call to the unknown region was immediate. The subjects, some Chinese and some Japanese, mentioned in this period are varied and numerous: landscapes of the four seasons, monthly observances, trees and plants, falconry, picnics, polo-playing, the paragons of noble deeds, the descent of the Amitābha, the ten Buddhist regions, etc. In Japan, during the Kamakura period (1190–1336), in making screens they followed the preceding Fujiwara in the main, both pictorially and technically.

The Sung Period.—In China itself in the Sung period (960–1279), the practice among prominent masters of painting and inscribing screens was not abandoned. On the contrary, painters like Tuan Yüan, Yen Hsiao, Wên T'ung and Hsü Tao-ning are known to have thus expressed their art; and noted calligraphers applied their brushes after the time-honored custom. The most significant branch of the art of the Sung period was the so-called Idealistic school of painting which was closely followed by the artists of the Yüan (1280–1367) and Ming (1365–1643) dynasties. Painters of this school attempted to express in their works certain noble thoughts and ideals. A landscape-painting, for example, was an essay which suggested the sublimity of nature and invited the beholder to identify himself with it. The inherent love of nature of the orientals, coupled with the teaching of *Ch'an* (in Japanese, *Zen*), produced artists who showed remarkable aptitude for depicting natural phenomena. *Ch'an* means "abstract meditation," the chief aim of its followers being to seek to separate the real from the unreal by divesting themselves of earthly thoughts and desires and by communing directly with nature. Inspired by this teaching, the artists developed marked individuality and their paintings were characterized by purity and suggestiveness. For their themes, the painters of the Idealistic school chose, be-

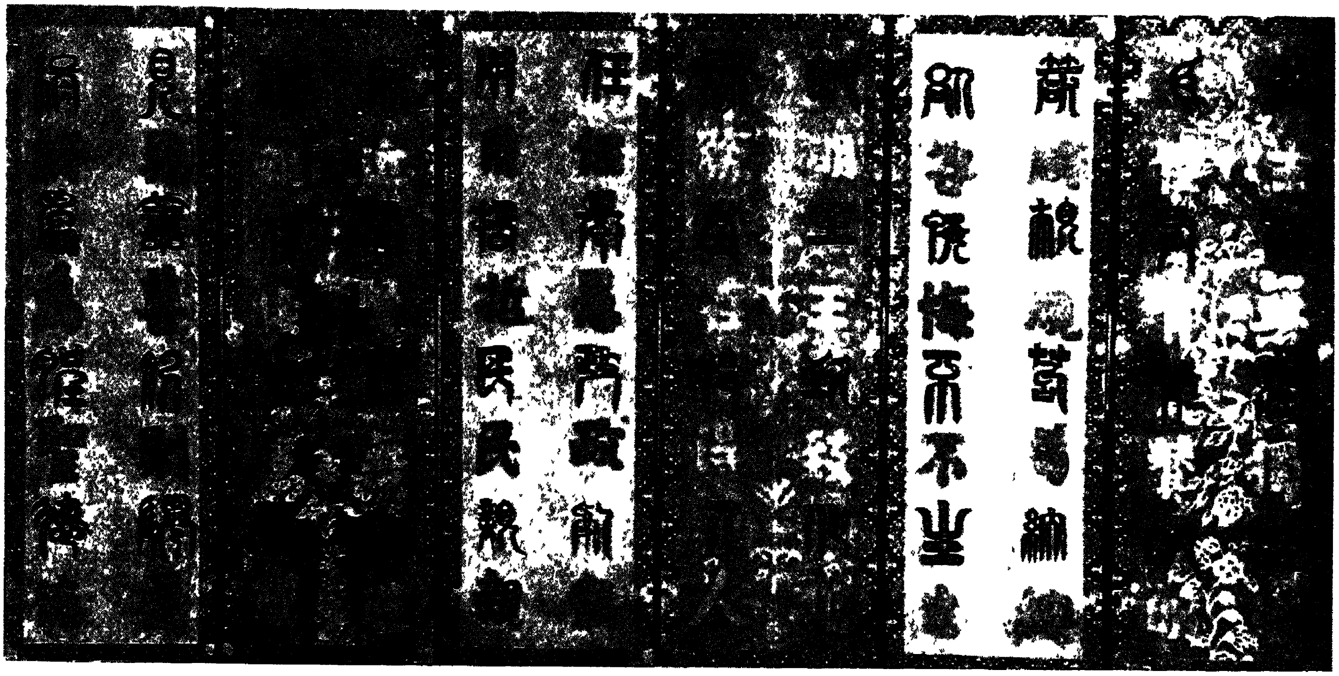
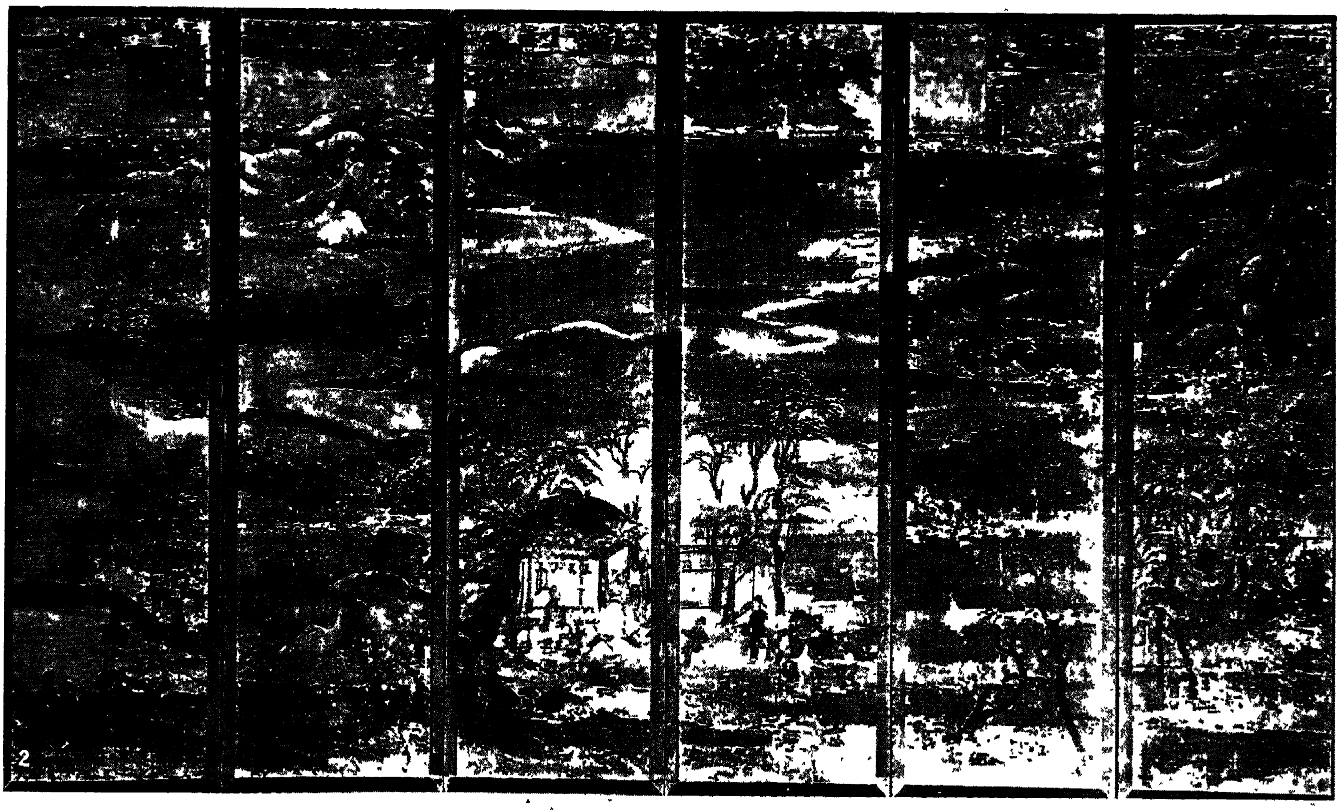
CHINESE IMPERIAL JADE SCREEN OF THE CH'IEN-LUNG PERIOD (1736–95 A.D.)

This Chinese imperial screen is composed of a gilt teakwood frame of eight folds set with spinach-green jade panels, carved on one side with landscape designs and on the other with flowers. The photograph was taken with a light arranged behind the screen to bring out the translucent quality of the jade





BY COURTESY OF (1) THE DIRECTOR OF THE IMPERIAL HOUSEHOLD MUSEUM, JAPAN, (2) (SHIMBI SHOIN, LTD) FROM "THE MASTERPIECES SELECTED FROM THE FINE ARTS OF THE FAR EAST"

A CHINESE AND A JAPANESE SCREEN IN THE T'ANG STYLE

1. Chinese screen of the eighth century painted with a precept in 48 ideographs, each character written both in the "seal" and in the "running" style. The panels, which are joined with cords, are coloured alternately red and green, with designs of clouds and other conventionalized forms in white. From the Imperial Collection in the Shosoin, Nara, Japan

2. Japanese landscape screen of the 11th century, probably after a T'ang original, depicts the visitation of a noble and his servants to a hermit's house set in a landscape of trees, hills and water. The over refinement of the drawings is characteristic of the "Japanese picture" style of the Fujiwara period (900–1189). From the Buddhist monastery of Toji at Kyoto

side landscapes, birds, animals and even withered trees and rocks, all of which ordinarily were treated in monochrome with China ink. Unfortunately there exists no example of the typical art of the Sung as applied on screens, nor are there any screens dating from the subsequent Yüan and Ming dynasties, in both of which it is recorded that painted and inscribed screens were produced. It is possible, however, that some of the paintings coming from these periods, now mounted as single hangings, were once panels of folding screens.

The Ashikaga Period.—Again turning to Japan, one can see an echo of the Chinese art of these three dynasties in paintings by Japanese artists of the Ashikaga period (1337–1573). Sōtan, Nōami, Sesshū, Masanobu and Motonobu are outstanding figures who painted in ink on screens after the Chinese idealists. A screen by Sōtan (Plate IV., fig. 1), who died in 1464, may be taken as a typical specimen of this style. The vigour of the brush, the subtle quality of the ink, the well-carried-out atmospheric perspective—all tell of the master hand which portrays the spirit of majestic nature. This screen is one of a pair which together show landscapes of the four seasons treated as one composition and consequently forming one composite whole. Beside the "Twelve Monthly Observances" and "Landscapes of the Four Seasons," such themes as "Flowers of the Four Seasons," "Farmers of the Four Seasons," "Lives of the 24 Paragons of Filial Piety," the "Eight Taoist Immortals," etc., frequently occur as single designs. The Idealistic school of painting was carried through the next period, the Momoyama (1574–1602), by artists of the Kano, the Unkoku and the Soga schools. In the screen (Plate IV., fig. 2) by Tōhaku (1539–1610) we see a remarkable monochrome; the varied shades of China ink being so used as to suggest the presence of colours, yet with no disturbing element of pigments and no sense of monotony.

A new type of screen introduced some time in the 14th century from Korea contributed much toward revolutionizing the general scheme of composition. Heretofore, a folding screen had consisted of a group of separate panels, each with brocaded borders, tied together by means of cords passing through holes pierced at the vertical edges of the panels (Plate III., fig. 1). In the Korean type the leaves were joined by paper hinges which were built into the body of the screen before the silk or paper for painting was pasted, a brocade border extending over the composite whole (*see* Plate IV.). Whereas in the former style the continuance of the design was interfered with by the frame and the brocade borders of each panel, in the latter style the tightly joined leaves made one surface for painting a picture.

Screens characteristic of the Momoyama period, the inherent love of the Japanese for simplicity notwithstanding, are more decorative in type, with backgrounds of gold leaf upon which appear bold designs in solid pigments on a massive scale. Eitoku (1545–90), who was the chief exponent of the style, is said to have supplied 100 pairs of screens for the Momoyama palace of the Taikō. He painted in two styles, ink and polychrome; the polychrome screens are very effective; for example, one of a pair in which are shown foreigners bringing tribute to the Chinese emperor, Tai-tsung, of the T'ang dynasty; the subject—"Barbarians Presenting Tribute"—being symbolic of the peace and prosperity of the country. The popular pictorial motives on screens at this time were "The Dragon and the Tiger," "Lions," "Old Pine Trees" (respectively symbolizing the conflict between spirit and matter, nobility and power, longevity and fidelity).

The Tokugawa Period.—In Japan during the Tokugawa period (1603–1868), a new movement in decorative painting was developed by Sōtatsu (1576–1643) who preserved the vigorous and broad brush-work practised by the masters in monochrome, but in place of ink used pigments on a gold ground. Even as he adopted the coloring of the old Yamato-é, so he took many themes from old sources, such as the romances of Genji and Isé, the wars of the Hogen and Heiji Eras, the wind and thunder gods. He was also a genius in the impressionistic treatment of flowers and waterscapes on screens. Following Sōtatsu's style, Kōrin (1658–1716) further enlarged upon decorativeness by introducing more brilliant colours and more daring composition. In the twofold screen (fig. 6) depicting violent waves is apparent this artist's largeness of conception and power of technique. In the Tokugawa days, artists in all schools—the Kano, the Tosa, the Genre, the Literary, the Realistic—exerted their artistic efforts on screens. In principle, the pictorial scheme for screens by these painters of varied styles had changed little from that of the preceding Ashikaga and Momoyama periods and it is still continued to-day. A bold design is treated in dissymmetry, yet is well balanced and effective; at the same time it bears a certain moral, historical, legendary or auspicious significance. The subjects treated were many and varied, including those which have already been referred to and also such themes as the "Eight Views of Hsiao Hsing," the "Ten Snow-Incidents," the "A-fang Pleasance," the "Four Gray-beards of the Shan Mountain," the "Seven Sages of the Bamboo Grove," the "Four Accomplishments," "Floating Fans," "Phoenixes," etc. Generally Japanese screens are six-fold, about 6 ft. in height and 12 ft. in width when stretched, and they are usually executed in pairs. Among the smaller type we may count "pillow" screens with brightly coloured pictures, which are placed about beds, and low, two-fold screens with simple decoration, or none at all, which are used in connection with the tea-ceremony (*q.v.*).

The Ch'ing Dynasty.—During the Ch'ing dynasty (1644–1911) in China, painting on screens was practised, as indicated by the presence of occasional examples dating from the last few centuries. But it is in screens of applied art that the period excels. It has already been said that the application of the minor arts to screens began in ancient China. The best known among such screens of recent centuries are the so-called "Coromandel screens" which are made of wooden panels finished with a coat of lacquer, through which designs—landscapes, figures, flowers, auspicious emblems, etc.—are incised and filled with various thick, opaque water-colours; a technique known from the Ming dynasty. A large portion, however, of the existing specimens are of the 17th to 19th centuries (Plate I., fig. 1). "Coromandel" has no bearing upon their provenance, but indicates that these screens of Chinese origin were shipped to European countries from the coast of Coromandel. Other screens in the category of lacquer are those with lacquered panels (sometimes coated with white oil paint) decorated in gold lacquer; and those of red carved lacquer. Screens of carved teakwood construction set with jade and porcelain plaques, or panelled with silks, tapestries or embroideries, are occasionally seen. (*See* Plate II.). (*See* also INTERIOR DECORATION, ORIENTAL; JAPANESE PAINTING AND PRINTS; CHINESE PAINTING; FLOWER ARRANGING; BATIK.)

Furniture.—As an article of furniture, the screen is an ornamental frame, usually of wood, but sometimes of metal, for protection from observation, draught or the heat of a fire. Screens are made of all shapes and sizes, and may consist of leather, paper or textile materials fastened to the framework; they may have several leaves or only one—thus a fourfold screen has four leaves. Fire screens are usually small, with a single leaf—indeed in the Georgian period of English furniture they often took the form of a circular, oval, heart-shaped or oblong piece of framed embroidery fixed to a wooden pole or upright, upon which they could be raised or lowered. This variety, which was called a pole-screen, was more effective as an ornament than as a protection. The hand-screen was light and portable, as the name implies. At the present time fire-screens are often of glass set in metal frames. The larger type of screen, with several leaves, is of uncertain origin, but probably first came into use towards the end of the 16th century. The earlier examples were of stamped or painted Spanish leather or of some rich stuff such as tapestry; at a later date lacquer was extensively used. They were tall enough to conceal the person sitting behind them, and were frequently exceedingly handsome and stately. (K. T.)

SCREW, a cylindrical or conical piece of wood or metal having a helical groove running round it. The surface thus formed constitutes an external screw, while a similar groove cut round the interior of a cylindrical hole, as in a nut, constitutes an internal screw. The ridge between successive turns of the groove is the "thread," and the distance between successive turns of the thread

is the "pitch." For screw as a mechanical power *see* MECHANICS; for the screw used to propel steamships *see* SHIPBUILDING.

Standardization of Screws.—All screws made to-day are copies of pre-existing or master screws, which are made in numerous forms. These are so standardized that a thread cut to a given standard in England fits its fellow thread cut to the same standard in America, Germany or elsewhere. The first attempt at securing uniformity in screw threads was made by Sir Joseph Whitworth about 1841. In the course of about twenty years the Whitworth system generally displaced the previous heterogeneous designs of threads, by the existence of which engineers' repairs had been rendered most inconvenient and costly, almost every establishment having its own "standard" set of screwing tackle.

When the Whitworth threads were accepted in England, Germany and the United States, it appeared as though they were established for ever in an impregnable position, as a unification evolved from chaos. Moreover, Great Britain at that time occupied a position of pre-eminence in manufacturing engineering, which was favourable to the establishment of an English system. But two things were wanting to permanence—the facts that the Whitworth threads were not based on the metric system, and that the United States was destined to come into rivalry with Great Britain. Metric systems became standardized on the continent of Europe and the Sellers thread in America overshadowed the Whitworth, though it is impossible to doubt that the Sellers like the Whitworth must in time be swallowed up by some one metric system.

The threads now recognized as standard are included in about eight great systems, out of about sixty that have been advocated and systematized. Their elements are shown by the diagram, fig. 1; but tables of dimensions are omitted, since they would demand too much space.

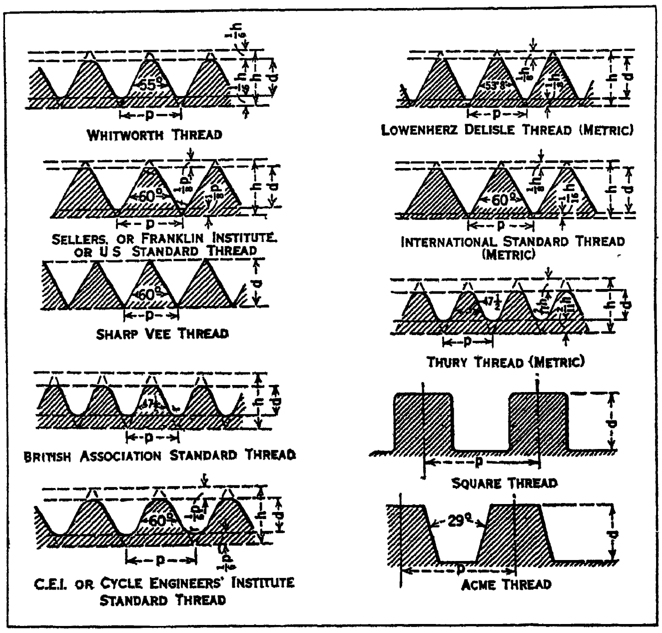


FIG. 1.—SECTIONS OF PRINCIPAL SCREW THREADS

METHODS OF CUTTING SCREWS

There are four methods employed for the cutting of screw threads: one by means of a single-edged tool held in the saddle of the screw-cutting lathe, and traversed horizontally only, the cylinder which is to receive the thread revolving the while; another by means of short master screws, hobs or leaders, controlling chasers or comb tools; the third by means of screw taps and dies, either the work or the tool being absolutely still. The fourth is by means of a milling cutter presented to the work in a special screw-milling machine, both the work and the cutter revolving.

In the Lathe.—The problem of screw-cutting in the lathe in the simplest form resolves itself into the relative number of revolutions of the lathe spindle and of the lead screw (fig. 2). If the two rotate at the same speed, the thread cut on the spindle axis will be equal in pitch to that of the lead screw. If the spindle revolves more slowly than the lead screw, a thread coarser than that in the latter will result; if it revolves more rapidly, one of finer pitch will be produced. The spindle is the first factor, being the *driver*, and the lead screw is *driven* therefrom through the change wheels—the variables—which determine the number of revolutions of the latter whether the same, or slower, or faster than the spindle.

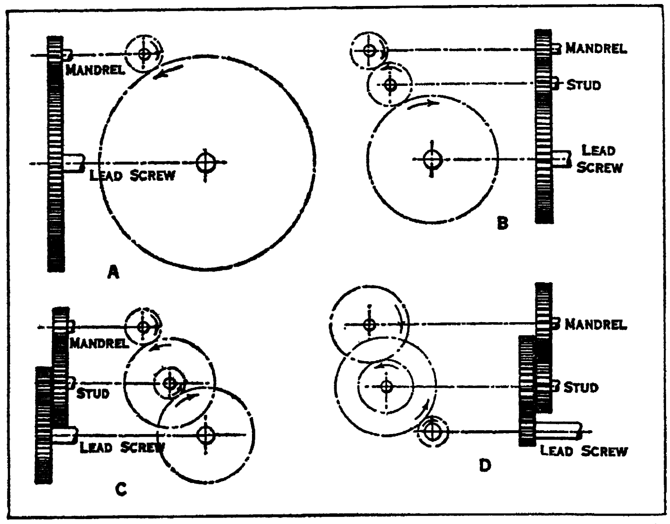

FIG. 2.—(A) SIMPLE TRAIN WHICH ROTATES LEAD SCREW IN OPPOSITE DIRECTION TO MANDREL, AND MAKES SLIDE-REST FEED AWAY FROM HEADSTOCK; (B) SIMPLE TRAIN WITH INTERMEDIATE WHEEL ON STUD, WHICH ROTATES LEAD SCREW IN SAME DIRECTION AS MANDREL; (C) TYPICAL COMPOUND TRAIN ARRANGED FOR CUTTING A SCREW FINER THAN THAT OF LEAD SCREW; (D) FOR SCREW COARSER THAN THAT OF LEAD SCREW

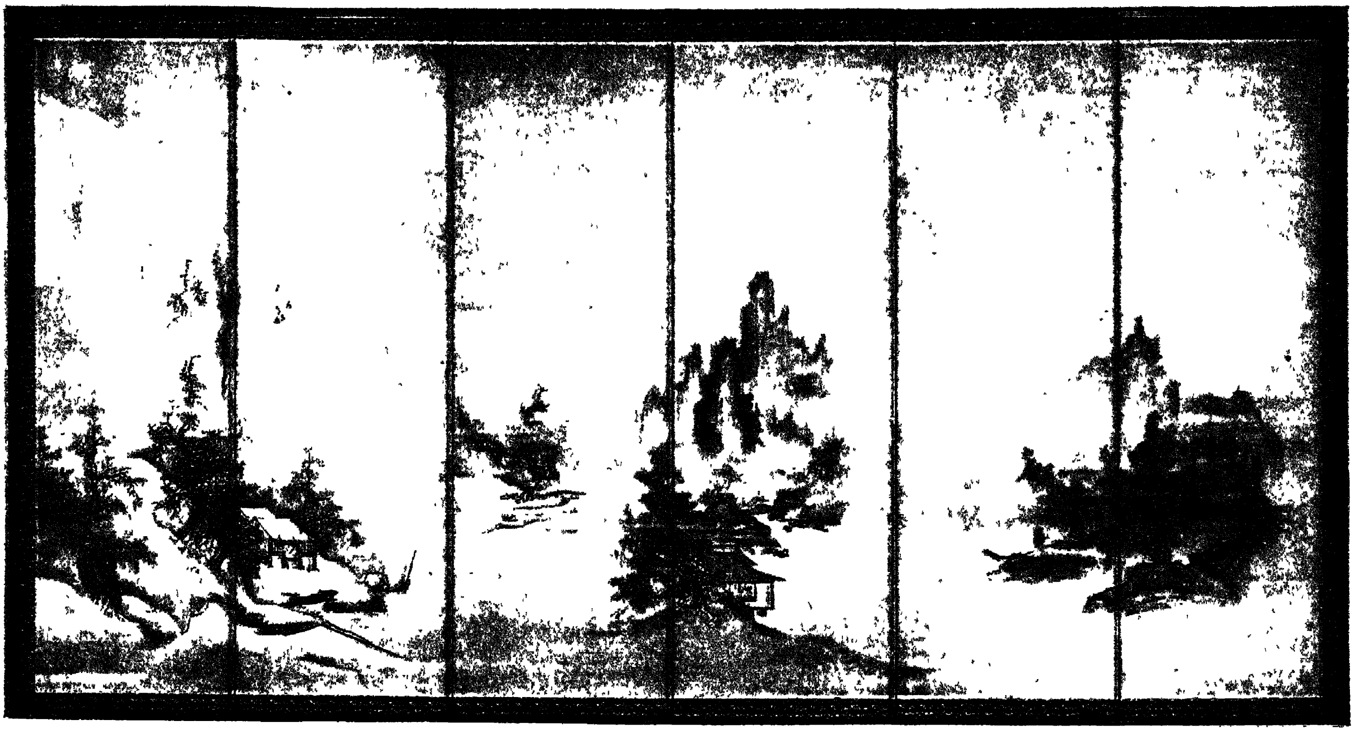
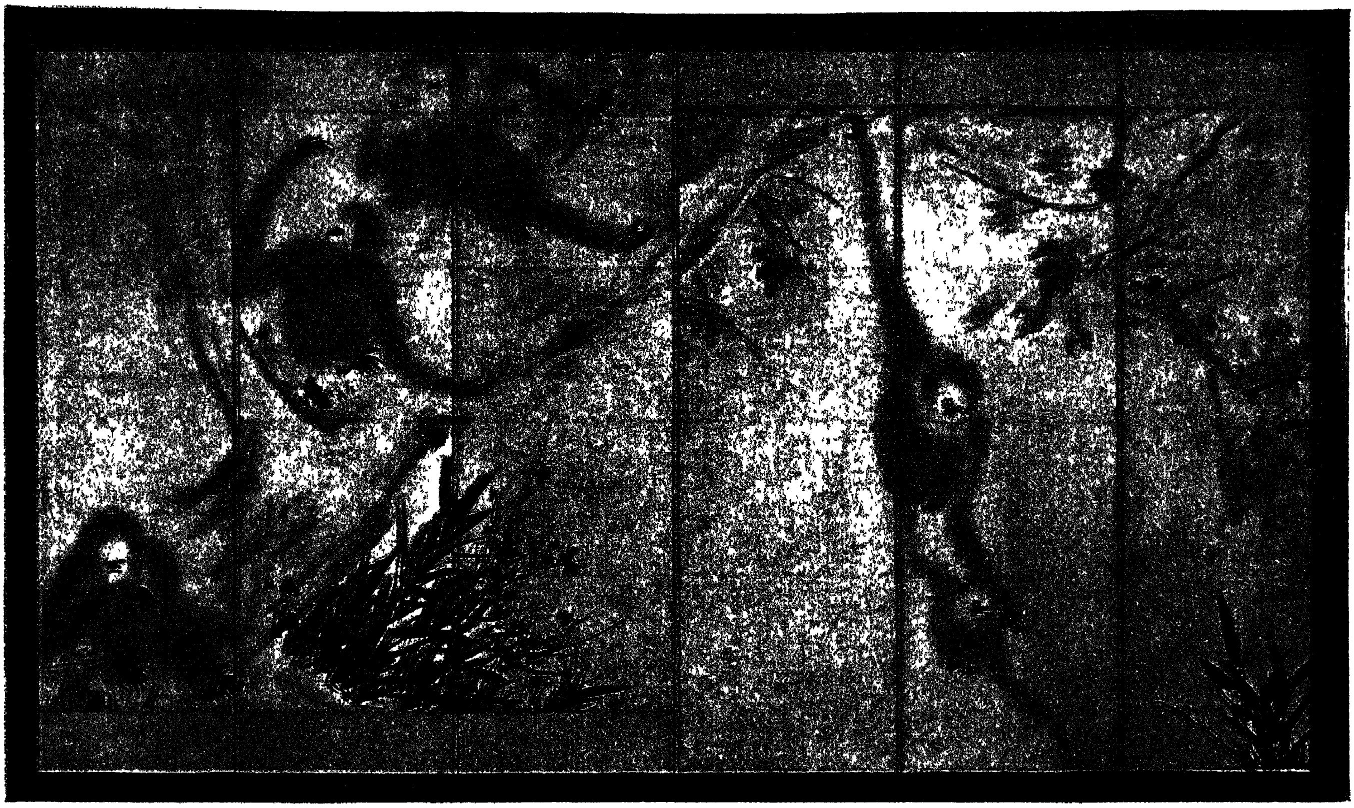
Screw-cutting in all its details is an extensive subject, including the cutting of what are termed odd or unequal pitches, that is, those which involve fractions, the catching of threads for successive traverses of the tool, the cutting of multiple threads and of right- and left-hand threads, which involve much practical detail.

The principle of screw-cutting may be stated briefly thus: the pitch of the guide screw is to that of the screw to be cut as the number of teeth on the mandrel or (headstock) wheel is to the number of teeth on the lead screw wheel. It is therefore simply a question of ratio. Hence for cutting threads finer than those of the lead screw, the guide screw must rotate more slowly than the lathe mandrel; and for cutting threads coarser than those of the guide screw, the lead screw must rotate faster than the lathe mandrel (fig. 2, C and D). When the ratios are ascertained, these facts indicate when the larger or the smaller wheels must be placed as drivers, or be driven. "Simple trains" are those which contain only one pair of change wheels; "compound trains" have two, three, four or more pairs (fig. 2), and are necessary when the ratio between the guide screw and the screw to be cut exceeds about six to one.

A device which has become very popular under the name of Hendey-Norton gears comprises a nest of change wheels, mounted and keyed on the end of the lead screw. A stud wheel is made to engage through an intermediate wheel with any one of the change gears, on the simple movement of a lever, giving different ratios for screw-cutting. These again are doubled or trebled by altering the ratios of other gears connected therewith, so that for each position of engagement of the stud wheel, two, or in some cases three, pitches can be cut. This avoids the waste of time involved in setting up fresh wheels on the swing-plate as often as a screw of different pitch has to be cut.

Another step in the direction of economy depends on the removal of all screw-cutting, except those screws which are of several feet in length, from the ordinary lathe to the special chasing and screwing machines. When there was no other method available except that of common dies operated by hand or carried in a screwing machine, there was good reason why a true cutting





BY COURTESY OF THE MUSEUM OF FINE ARTS, BOSTON

TWO JAPANESE SCREENS

Above: Landscape, by Oguri Sōtan (1398–1464), painted in monochrome, with gold wash, on paper. It is one of a pair of six-fold Japanese screens in the Fenollosa-Weld collection

Below: Spider-monkeys, by Hasegawa Tōhaku (died 1610), painted in monochrome on paper. It is one of a pair of six-fold Japanese screens in the Bigelow collection

tool should be operated in the lathe through change wheels. But the reason no longer exists, since for the single cutting tool of the lathe the two or three cutters of the chasing and screwing machines (figs. 3 and 4) are substituted, and the hollow mandrel embodied in the latter permits of screws being cut and parted from the solid bars of several feet in length.

The second method of cutting screws is that by means of hobs or leaders, and either comb or single-edged tools. That is, a

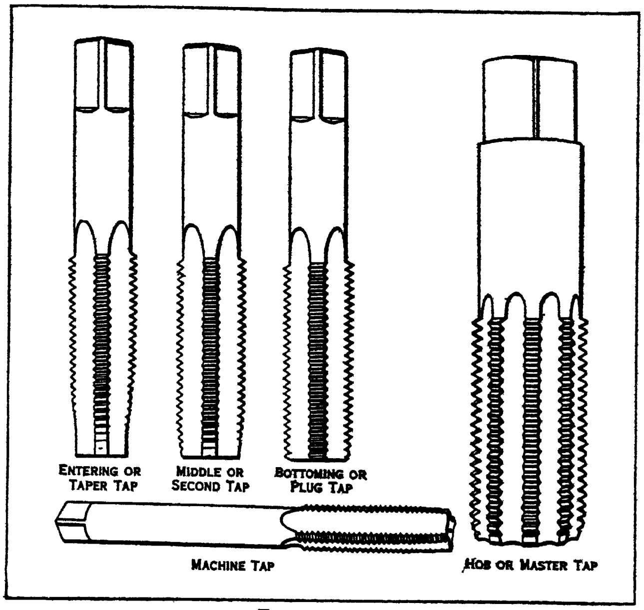


FIG. 3.—TAPS

short standard screw is mounted somewhere on the lathe, at the rear, or in front, and a nut partly embracing this becomes a guide to a bar which is attached to the tool slide directly. These are termed chasing lathes. Their value lies in the cutting of screws of but a few inches in length, of which large numbers are required, a familiar example being the screwed stays for the fire-boxes of steam boilers, hundreds of which are used in a single boiler.

By Taps and Dies.—The third method embodies the use of taps and dies in their numerous designs. The simpler forms used are those operated by hand at the bench, from which all the machine taps and dies have been elaborated. The tap is the solid screwed cylindrical tool which cuts an internal thread (fig. 3); the die is the hollow tool which cuts a thread on the outside of a cylinder (fig. 4).

In all taps and dies the problem is to cut a screw, of which the

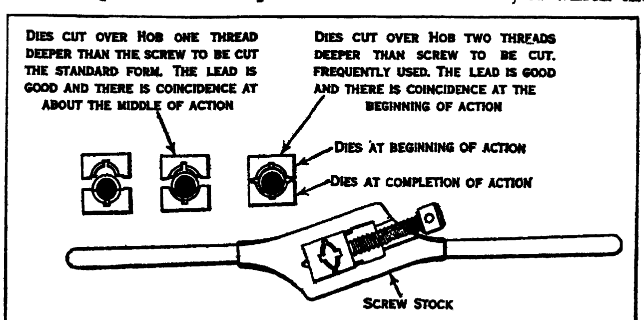

FIG. 4.—DIES

angle of thread changes from point to root, with tools whose angle must remain constant. In taps there is no choice of angle, since they must be the exact counterparts of the tapped threads when finished. But in dies a compromise is made by cutting them with hobs, or master taps, one thread larger than the thread to be cut by the dies. Briefly, the practical effect is that the dies are only counterparts of the thread to be cut at about the middle part of their action.

Dies are held in stocks. In the common die stocks one adjustable die is moved forward with a screw, which forms one of the handles of the stock, or a separate tightening screw is used at right angles with the handles, or the tightening screw is set diagonally in relation to the handle. Sir Joseph Whitworth's well known "guide" screw stock (fig. 5) is a typical example of the embodiment of the principle just stated, the dies being cut over a hob two depths of thread larger than the screw; one, a broad die, is used for guidance only, and two narrow dies do all the cutting.

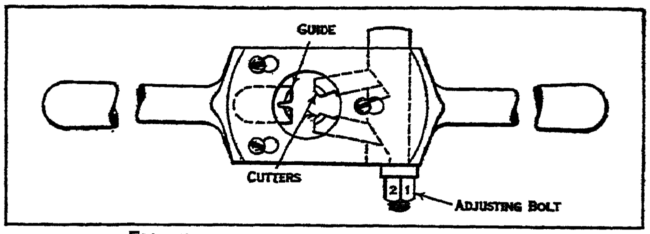

FIG. 5.—WHITWORTH GUIDE-SCREW STOCK

The guide-screw stock derives its name from the fact that it embodies a guide *a* distinct from the cutters *b,b,* the guide doing very little actual cutting; it is one of the best tools for screw-cutting outside the lathe, but some of the American types of dies give very accurate results, especially when they are combined with a guide placed in advance of the dies, to keep them truly parallel on the work.

Machine Work.—Hand tapping and screwing has long been confined to occasional pieces of work done by the fitter at the bench, the erecter and repairer. Screws and tapped holes required in quantities are done on machines which include numerous types, at a rate of production which would seem incredible were it not so common. For cutting common screws of no very great length the lathe has long been superseded by the various screwing machines. The earlier forms were provided with clutch mechanism for running the solid dies back off the thread, in imitation of the action of the hands, and the dies could not cut a complete thread at one traverse, two or three traverses being necessary in the production of a full thread. In the modern screwing machines (fig. 3) the cutters are closed and released by cam mechanism, and all threads except those of large diameter are cut at a single traverse. Common bolts and nuts are cut in machines of this kind, machine taps, which are longer than hand operated taps, being employed in the same machines.

But the smaller screws made in large quantities, and screws which have to be cut on pieces of work on which other operations, as turning, boring, facing, knurling, have to be performed, are made in the numerous capstan or turret lathes, the dies or taps being held in the turrets. In most cases, however, the dies are held in a chuck which is inserted in one of the holes in the turret and which

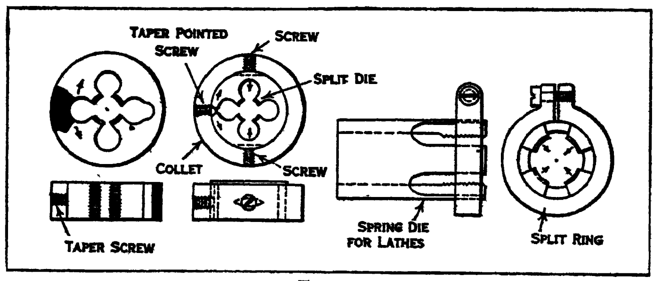

FIG. 6

is better for the cutting of the finer screws. More valuable than any other single improvement is the automatic opening of many dies used in turret lathes, by which the running back of the die over the work is avoided. They are so beautifully contrived that contact with a stop, the position of which can be regulated, arrests the cutting action and causes the dies to fly open away from the screw, so that the turret can be slid away instantly, while the dies close in readiness for the next screw.

Sizing Taps are used for the finishing of threads which are required to be finished so uniformly as to be interchangeable one with the other. These are ordinary plug or second taps, generally short in length, and as they remove but a mere trifle of material

they retain their size for a very long time. The case of sizing taps is more difficult than that of dies, because a die can be readily compressed to an extent sufficient to compensate for wear, but a tap has to be expanded.

Screw Milling and Thread Grinding.—Screw milling, the latest development in screw-cutting, involves the use of a special machine, something like the lathe in outline, the piece of work to be threaded being rotated in the axis of the machine. The cutter is carried in a head, with swivelling arrangements, to provide for variations in screw angles, and is rotated at speeds suitable for the metal or alloy being cut. The necessary traverse is imparted either to the work or to the cutter, according to the design of machine, by lead screw and change gears. This method is employed to a considerable extent, chiefly for cutting coarsely threaded screws and worms. The great advantage which the revolving cutter possesses over the single-edged tool is its rapidity of action, by which threads may be produced more quickly than in the lathe.

Much of the precision finishing of screws is now performed with the aid of grinding wheels, which will operate on hardened screws as well as on unhardened. Some of this work is done in small precision lathes, while there are worm-thread grinders for accurately finishing the flanks of the threads of large screws or worms.

TESTING SCREWS

The screws cut in engineers' shops are sufficiently true for all practical purposes. But the fact remains that no guide screw yet made is true, and no true screw can be made apart from the use of devices which are unknown in the machine shop. The microscope is brought into requisition for testing standard screws, but commercial screws simply have to pass the test of gauges. The microscope class of measuring machine makes use of cross-hairs, adjusted to various portions of the screw, and a micrometer apparatus for fine reading of differences. At the National Physical laboratory, Teddington, England, there are fine machines for testing pitch errors by the system of magnification of the movement of a style brought into contact with the threads of the screw undergoing examination. The magnification is 750 in one case. The results of errors in any screw sent for test are shown on a chart.

An accurate mode of testing effective screw diameters is by means of what is termed the "three-wire" method. Three hard steel wires lapped to a high state of accuracy are laid in the grooves of a screw, two on one side and one on the other, and measurement is taken over the lot with a micrometer calliper, or in a measuring machine.

Screw thread gauges are considered in the article TOOL, but a new kind of testing has arisen, which does not come under the head of a tool, since it depends on optical methods. Briefly, a magnified image of the screw thread, as much as fifty times larger, is thrown on a screen by a lantern. The screw rests in a cradle in front of the lens, and any number of screws can be tried in succession. First a master screw or gauge is put in and its shadow projected on to a tolerance chart on the screen some distance. When the cradle has been adjusted so that this master screw appears correctly on the chart, the screws to be tried will reveal, by their position on the chart, whether they are too large or too small, or of inaccurate pitch. Short framed lines indicate the boundaries of a good thread while a faulty shadow is seen to be undersize. Errors of pitch are revealed by the shadow standing too far to one side.

The problem of producing a true screw has occupied investigators since the days of Henry Maudslay (1771–1831). The great difficulty is that of attaining accurate pitch, so that the distances between all the threads shall be uniform, and consequently that a nut on the screw shall move equably during the rotation. The importance of this point is felt in the dividing engines of various classes employed for ruling, and in measuring machines used for testing standards of length.

There are a number of methods of correcting the errors in screws; the principal one is that of retarding or accelerating the traverse motion of the screw-cutting tool by means of a compensating lever bearing on a compensating bar, which is formed after observations have been made on the degree of accuracy of the leading screw used to propel the tool carriage. The original errors in the leading screw are therefore eliminated as far as possible. The inspection of the screw is done by means of the microscope working in conjunction with a line measure fastened down parallel with the axis of the screw, so that the coincidence or otherwise of the screw pitches with the subdivisions of the measure may be compared. (J. G. Ho.)

SCREWDRIVER, the tool which drives screws, must be made of good steel and suitably tempered so that it will not snap off through being too hard, or twist or bend through being too soft. The chief interest in this connection in manufacturing processes and repairs attaches to the mechanically operated screw-drivers which vastly speed up the rate of removing or inserting screws. Some are driven by a flexible shaft actuated from a cord and pulley, the shaft being manoeuvred about anyhow to suit the situation of the screws. Or a pneumatic or electric drill is fitted with the blade, and held in the hands anywhere required. Some small articles demanding the use of numerous screws are placed under a fixed screw-driving machine, the spindle of which carries the driver blade, pressed down by a lever. In wood working, screw-driving machines are largely used in mass production.

For hand use only the *ratchet* and the spiral types are very convenient. The former enables the grip to be maintained on the handle the whole of the time, while the screw is turned in either direction, leaving one hand free. The latter sends the screw home or runs it out on giving a straight push to the handle. Some drivers combine both actions for selection as desired.

SCREW-PINE, the popular name for plants of the genus *Pandanus,* which are shrubs or trees of peculiar habit, having a main stem and a few branches at the ends of which is a tuft of long, stiff, narrow leaves closely arranged in three strongly twisted lines. The stem forms stout roots some distance above the ground; they grow obliquely downwards to the soil, and owing to the decay of the lower part of the stem the plant is often supported merely by these strong prop-like roots. The ripe fruits are borne in often very large spherical or cylindrical heads, which are often extremely hard. The genus is the principal one of the family Pandanaceae, a small family of monocotyledons, which is widely distributed through the tropics of the Old World, especially in the islands of the Malay archipelago and of the Indian and Pacific oceans.

SCREW-PROPELLER: *see* SHIPBUILDING.

SCRIABIN, ALEXANDER NICHOLAEVICH (1871–1915), Russian composer, was born at Moscow on Christmas Day 1871 (O.S.). His father was a lawyer; his mother, a good pianist and pupil of Leschetizsky, died when he was one year old. His schooling was received in the Moscow Cadet Corps, but he never showed any liking for the military career for which he was intended, and at 18 entered the Moscow Conservatoire of Music where he was a pupil of Safonov and Taneev. On leaving the conservatoire Scriabin was greatly helped by the patriotic music publisher Belaiev, who brought out his earlier works and arranged a European piano recital tour for him. At 20 he returned to Moscow and joined the conservatoire staff. Later he again travelled, this time for six years, visiting the United States amongst other countries. He then settled in Brussels for some time, and in 1910 returned to Moscow. In 1914 Scriabin visited England, giving two piano recitals, playing his own concerto and appearing as pianist in his *Prometheus.* He was then suffering from a tumour of the lip, from which, soon after his return, he died, April 14, 1915.

As a composer, Scriabin represents what may be called the classical-romantic school carried forward to its most advanced point. The form of his sonata and symphony movements he derives from Mozart, through Beethoven; however bewildering these may at first sound, they will be found, on further hearing, to be laid out on essentially the Mozart-Beethoven lines. In his pianistic idiom and general pianistic qualities of style, Scriabin derives largely from Chopin, of whose work he was a great admirer. All this then indicates a conservative side to his com-

position, but he was more radical in his harmonies, and it was, probably, largely the novelty of these that retarded appreciation of his later works. It is said that Scriabin gradually evolved a synthetic scale of upper partials or "mystic" chord of superposed 4ths. (C,D,E,F#,A,B♭, or as a chord, C,F#,B♭,E,A,D). One's actual impression, however, of his harmony is of an almost ceaseless chromaticism and of an almost unbroken use of the dominant chord with the flat 7th, 9th, 13th, sharpened 4th, and most frequent of all, the sharpened 5th (or flattened 6th). It is seldom one recognizes his chord of superposed 4ths as such, excepting at times the characteristic two perfect 4ths at the top. In his later work he makes still further harmonic excursions, notably with sharp 7ths or flat 2nds. The hint of this new harmonic scheme may be seen in the earliest compositions, and its development was fairly regular and consistent, until it came to dominate his later output. In his later works he discards entirely the old key signatures. In his orchestration Scriabin calls for a large force, and uses it very freely: his scores are exceedingly contrapuntal in texture, the various instruments moving very independently and weaving together their respective themes: muted brass plays a large part in his orchestral colour scheme. In the first symphony a chorus is used in the finale; the *Poem of Fire* also uses a chorus, but in an orchestral way, no words being supplied. For the last-named work the composer also wrote an optional part for a "Tastiera per luce," or keyboard of light, the intention being that varying colours should play upon a screen as the work was being performed. The composer was greatly interested in theories as to a correspondence between the musical scale and the scale of colours. In his great *Mystery* (left unfinished at his death) music, dance, speech, perfume and colour were to be combined; this work was to be rather a work of ritual than of art, and was to express its author's idealistic mysticism through the medium of 2,000 participants.

It is usual to look upon Scriabin's musical work as largely the expression of theosophical views, and undoubtedly much of his inspiration was drawn from the works of Blavatsky and others. He was not, however, a close reader or a careful thinker. Seizing the main idea of a book or a creed, he would neglect the details, and then his imagination would quickly develop a huge scheme of thought having little relation to what he had read. The titles of many of his works and of their separate parts, and the marks of expression affixed to particular passages, indicate plainly the existence of a spiritual "programme." The emancipation of the human soul through ceaseless striving, and its achievement of self-expression, may be said, very roughly, to represent the general sense of the spiritual basis of Scriabin's musical works.

The works of Scriabin have been variously classed into periods. A logical classification is into four periods as follows: 1st period, with a strong Chopin influence; the dividing line between this and the 2nd period runs through the first symphony, and the 2nd period shows some Wagner and Liszt influences; the dividing line between this and the 3rd period runs through the fifth sonata, and a 4th period begins with the *Poem of Fire*.

Among Scriabin's principal works are the following. For orchestra: *Reverie*, op. 24; first symphony, op. 26; second symphony, op. 29; third symphony (or *Divine Poem*), op. 43; fourth symphony (or *Poem of Ecstasy*), op. 54; *Prometheus* (or *"Poem of Fire"*), op. 60. For piano: ten sonatas, together with a very large number of preludes, études, impromptus, mazurkas, poems, etc., including the great *Vers la Flamme* poem and the much-discussed last work, the Five Preludes (op. 74). For piano and orchestra: Concerto, op. 20. No songs or chamber music are included in Scriabin's output. (P. A. S.)

SCRIBE, AUGUSTIN EUGÈNE (1791–1861), French dramatist, was born in Paris on Dec. 24, 1791. His first piece, *Le Prétendu sans le savoir,* was produced without his name at the Variétés in 1810, and was a failure. Numerous other plays, written in collaboration with various authors, followed; but Scribe achieved no distinct success till 1815, when *Une Nuit de la garde nationale,* written in collaboration with Delestre-Poirson, made him famous. Thenceforward his fertility was unceasing and its results prodigious. He wrote every kind of drama—vaudevilles, comedies, tragedies, opera-libretti. To the Gymnase theatre alone he is said to have furnished a hundred and fifty pieces before 1830. This extraordinary fecundity is explained by the systematic methods of collaboration which he established. He had a number of co-workers, one of whom supplied the story, another the dialogue, a third the jokes and so on. He is said in some cases to have sent sums of money for "copyright in ideas" to men who were unaware that he had taken suggestions from their work. Among his collaborators were Jean Henri Dupin (1787–1887), Germain Delavigne, Delestre-Poirson, Mélesville (A. H. J. Duveyrier), Marc-Antoine Desaugiers, Xavier Saintine and Gabriel Legouvé. His début in serious comedy was made at the Théâtre Français in 1822 with *Valérie,* the first of many successful pieces of the same kind. His industry was untiring and his knowledge both of the mechanism of the stage and of the tastes of the audience was wonderful. He was for fifty years the best exponent of the ideas of the French middle classes. The best-known of Scribe's pieces after his first successful one are *Une Chaîne* (1842); *Le Verre d'eau* (1842); *Adrienne Lecouvreur* (1849), in conjunction with Legouvé; *Bertrand et Raton, ou l'art de conspirer;* and the libretti of many of the most famous operas of the middle of the century, especially those of Auber and Meyerbeer. The books of *La Muette de Portici, Fra Diavolo, Robert le Diable,* and of *Les Huguenots* are wholly or in part by him. Scribe died in Paris on Feb. 20, 1861.

His *Oeuvres complètes* appeared in seventy-six volumes in 1874–85. *See* Legouvé, *Eugène Scribe* (1874); and N. C. Arvin, *E. Scribe and the French Theatre, 1815–60* (Cambridge, Mass., 1924).

SCRIBES, a famous Jewish group frequently mentioned together with the Pharisees (*q.v.*), in the Gospels. Their rise is connected in the closest possible manner with the study of the *Torah* (Law). This study and understanding of the *Torah* was highly complex in character; it followed, therefore, that the existence of a distinct body of experts on the subject became a necessity. Thus there arose the scribes, with whom *Torah*-study was a matter of professional occupation. Originally this occupation belonged to the priesthood, for the priests were at first, both the guardians and teachers of the Law. Ezra himself was both priest and *Sopher* ("scribe"). But by degrees the study of the law was pursued by others besides the priests—for the *Law* was meant equally for layman and priest, and the one had as much interest in it as the other—so that there arose an independent class of *Torah*-students, who in time supplanted the priests as teachers of the people, and became the recognized official exponents of the law. At the same time, this did not necessarily exclude scribes from being priests for, on the testimony of Philo, we know that in the synagogues priests often undertook the duty of reading the law and expounding it to the people, a duty which belonged specifically to the scribes; so that there is no reason to believe that scribes were never priests. In the first instance, scribes occupied themselves exclusively with study; they were not allowed to pursue any other calling, lest their thoughts should be withdrawn from *Torah*-study; *see* Ecclus. xxxviii. 24: "The wisdom of a learned man cometh by opportunity of leisure: and he that hath little business shall become wise . . ." But in later days it became absolute duty for them to have some other calling besides, in order to earn a livelihood, the reason being that all labour for the law had to be gratuitous. For the most part the scribes belonged to the Pharisaic party; but as the one qualification for being a scribe consisted in being "learned in the Law" there must have been scribes in the Sadducean party as well, indeed this is implied in the New Testament (*see* Mark ii. 16, Luke v. 30, Acts xxiii. 9). As the scribes were occupied with the administration of the law as well as with its study, they were also called "Lawyers" (Matt. xxii. 35, Luke vii. 30, x. 25, xi. 45, 46), or "teachers of the Law" (Luke v. 17, Acts v. 34); "Lawyer" and "Scribe" are synonymous, for which reason they are never mentioned together in the New Testament. But as administrators of the law it followed, in a natural course, that the scribes should also be among those who saw to its being carried out; so that they also had the power of sitting as judges, and therefore also of passing sentence upon those who were guilty of breaking the

law. Hence scribes were among those who composed the great Sanhedrin at Jerusalem, and as they were the ones whose special study of the law made them experts, it cannot be doubted that their influence in this supreme court must have been considerable.

The difference between the scribes and the pharisees was briefly this—the scribes handed down the traditional, *i.e.*, the Oral Law as well as the Written Law, and explained it; the pharisees carried out in actual practice what was prescribed. This, of course, does not mean to say that the scribes did not also strictly observe the legal enactments; but that their special duties constituted them a class distinct from the pharisees is clear from the way in which they are differentiated in the New Testament, for there we read of the "Scribes of the Pharisees" (Mark ii. 16, Acts xxiii. 9), and of "the Pharisees and their scribes" (Luke v. 30), showing clearly that the scribes were distinct from the Pharisees. *See* G. F. Moore, *Judaism.* (G. H. B.)

SCRIPPS, EDWARD WYLLIS (1854–1926), American newspaper publisher, was born at Rushville (Ill.) June 18, 1854. He was brought up on a farm in Winchester county and in 1872 joined the staff of the Detroit *Tribune,* then owned by his brother James. Fire destroyed this paper in 1875 and the same year J. E. Scripps founded the Detroit *Evening News,* with E. W. Scripps as city editor. Three years later the latter founded the Cleveland *Penny Press,* which under his direction achieved immediate success. He gradually acquired other journals in Ohio and elsewhere, which later became known as the Scripps-Howard group.

In 1896 he, in conjunction with Milton A. McRae, formed the Scripps-McRae Press Association for the purpose of providing his papers with cable news. He also, in 1901, organized the Newspaper Enterprise Association, with the object of supplying features to local papers. In 1908 the Scripps-McRae association was merged with the publishers' press association and the Pacific coast press association, under the name of the United Press Association, Mr. Scripps holding a controlling interest. In 1917 his health broke down under the strain of war work and in 1920 he retired from business activity. In this same year he founded and endowed *Science Service,* a news bureau for the dissemination of scientific facts. In 1924 he transferred control of his various interests to his son Robert P. Scripps. He died on board his yacht in Monrovia bay, Liberia, West Africa, on March 12, 1926.

SCROFULA or **STRUMA,** the general names formerly given to the disease now termed tuberculosis (*q.v.*)—"scrofulous," "strumous" and "tuberculous" being nearly interchangeable. The particular characters associated with "scrofula" have, therefore, varied at different periods when the real nature of the disease was misunderstood; but essentially what was meant was tuberculosis of the bones and lymphatic glands, with its attendant symptoms, and it is in this sense that the word survives. The old English popular name was "king's evil," so called from the belief that the sovereign's touch could effect a cure. This superstition can be traced back to the time of Edward the Confessor in England, and to a much earlier period in France. Samuel Johnson was touched by Queen Anne in 1712, and the same prerogative of royalty was exercised by Prince Charles Edward in 1745.

SCROGGS, SIR WILLIAM (*c.* 1623–1683), lord chief justice of England, was the son of a butcher of sufficient means to give his son a university education. Scroggs went to Oriel college, and later to Pembroke college, Oxford. There is some evidence that he fought on the royalist side during the Civil War. He was called to the bar in 1653, was appointed a judge of the common pleas in 1676, and two years later was promoted to be lord chief justice. As lord chief justice Scroggs presided at the trial of the persons denounced by Titus Oates for complicity in the "popish plot," and he treated these prisoners with characteristic violence and brutality, overwhelming them with indecent sarcasm and abuse while on their trial, and taunting them with savage mockery when sentencing them to death. He may at first have been a sincere believer in the existence of a plot; at all events he did nothing to test the credibility of such perjured witnesses as Oates, Bedloe, and Dangerfield. At the trial in Feb. 1679 of the prisoners accused of the murder of Sir Edmund Godfrey he gave a characteristic exhibition of his methods, including a tirade against the Roman Catholic religion. But Oates' next move, accusing the queen's physician, Wakeman, seemed to be going too far, and in the succeeding trials Scroggs impugned the testimony of Bedloe and Oates, thereby incurring great unpopularity in the country. Oates and Bedloe now arraigned him (1680) before the privy council for misconduct of the Wakeman case, but he was acquitted. The same year he discharged the grand jury to save the duke of York from trial as a popish recusant. In Jan. 1681 he was impeached; dissolution saved him, but he was removed from the bench. He died on Oct. 25, 1683.

Scroggs was perhaps the worst of the judges who disgraced the English bench at a period when it had sunk to the lowest degradation; and although his infamy is less notorious than that of Jeffreys, his character exhibited fewer redeeming features. Scroggs was the author of a work on the *Practice of Courts-Leet and Courts-Baron* (London, 1701), and he edited reports of the State trials over which he presided. He was the subject of many contemporary satires.

F. Stephen, *History of the Criminal Law of England* (3 vols., London, 1883); Henry B. Irving, *Life of Judge Jeffreys* (London, 1898).

SCROPE (skrōōp), an old English family of Norman origin. Sir William le Scrope, of Bolton, in Wensleydale, Yorkshire, had two sons, HENRY (d. 1336) and GEOFFREY (d. 1340), both of whom were in succession chief justice of the king's bench and prominent supporters of the court in the reign of Edward II. Henry was father of RICHARD LE SCROPE, 1st Baron Scrope of Bolton (*c.* 1327–1403), chancellor of England, an active adherent of John of Gaunt. Having been knight of the shire of Yorkshire in the parliament of 1364, he was summoned to the upper house as a baron by writ in 1371, when he was made treasurer and keeper of the great seal. In 1378 Lord Scrope became chancellor; he attempted to curb the extravagance of Richard II., and was dismissed in 1382.

His eldest son WILLIAM (*c.* 1350–1399) was created earl of Wiltshire in 1397 by Richard II., and he bought the sovereignty of the Isle of Man from the earl of Salisbury. In 1398 he became treasurer of England. His execution at Bristol was one of the first acts of Henry IV., and the irregular sentence of an improvised court was confirmed by that monarch's first parliament. Wiltshire's father, Lord Scrope, and his other sons were not included in the attainder, but received full pardon from Henry. Scrope, who was the builder of Bolton Castle, his principal residence, died in 1403. He was succeeded in the barony by his second son, Roger, whose descendants held it till 1630. On the death of EMMANUEL SCROPE, 11th baron (1584–1630), who was created earl of Sunderland in 1627, the earldom became extinct.

SIR GEOFFREY LE SCROPE (d. 1340), chief justice of the king's bench as mentioned above, uncle of the first Baron Scrope of Bolton, had a son Henry (1315–1391), who in 1350 was summoned to parliament by writ as Baron Scrope, the designation "of Masham" being added in the time of his grandson to distinguish the title from that held by the elder branch. HENRY LE SCROPE, 3rd Baron Scrope of Masham (*c.* 1376–1415), was a favourite of Henry V., by whom he was made treasurer in 1410 and employed on diplomatic missions abroad. But in 1415 he was concerned in a conspiracy to dethrone Henry and was executed at Southampton, when his title was forfeited. It was, however, restored to his brother John in 1455; and it fell into abeyance on the death, in 1517, of Geoffrey, 11th Baron Scrope of Masham, without male heirs.

See Sir N. H. Nicolas, *The Scrope and Grosvenor Controversy* (2 vols., London, 1832), containing much detailed information about the various branches of the Scrope family; J. H. Wylie, *History of England*

under Henry IV. (4 vols., London, 1884–98); Edward Foss, *The Judges of England* (9 vols., London, 1848–64); G. P. Scrope, *History of the Manor and Ancient Barony of Castle Combe, Wilts* (London, 1852); G. E. C., *Complete Peerage,* vol. vii. (London, 1896).

SCROPHULARIACEAE, in botany, a family of seed plants belonging to the sympetalous section of Dicotyledons and a member of the series Tubiflorae. It is a cosmopolitan order containing about 200 genera with about 2,600 species; the majority occur in temperate regions, the numbers diminishing rapidly towards the tropics and colder regions. About 30% of the species are annual herbs, such as eyebright (*Euphrasia officinalis*), cow-wheat (*Melampyrum*), and species of *Veronica;* more than 60% are biennial or generally perennial herbs and undershrubs, such as species of *Veronica,* mullein (*Verbascum*), foxglove (*Digitalis purpurea*), etc., while shrubs and trees are rare; *Paulownia,* a native of the mountains of Japan, a tree with large leaves and handsome panicles of violet flowers, is grown in European gardens.

The stem is sometimes prostrate and creeping, as in ivy-leaved toad-flax (*Linaria Cymbalaria*) and some of the native British Veronicas, but generally erect as in foxglove, figwort, mullein, etc.; a few are climbers as *Rhodochiton* and *Maurandia.* The South African genera *Hyobanche* and *Harveya* are parasites almost devoid of chlorophyll with scale-like leaves; and many genera are semiparasitic, having green leaves, but attaching themselves by root-suckers to roots of grass, etc., from which they derive part of their nourishment; such are *Euphrasia, Rhinanthus, Pedicularis,* etc. A few genera are aquatic, e.g., *Ambulia* (Old World Tropics), and have much divided submerged leaves and entire aerial leaves. The flowers are solitary in the leaf-axils, as in *Mimulus,* species of *Linaria,* etc., or form spikes or racemes which are terminal as in foxglove, species of *Veronica,* etc., or axillary, as in *Veronica* (*Chamaedrys* section). The flowers are hermaphrodite, hypogynous and zygomorphic in the median plane, being often more or less two-lipped, and having five sepals joined below and persisting in the fruiting stage, five petals uniting to form a corolla of various shape, generally four stamens, the fifth (posterior) being suppressed or represented by a rudiment, while the anterior pair are longer than the posterior, and two generally equal carpels in the median plane forming a two-celled ovary containing numerous anatropous ovules on a thick axile placenta, and bearing a simple or bilobed style.

When a terminal flower is present it becomes regular as in toad-flax, where radial symmetry is produced by development of a spur to each petal—such flowers are termed peloric; all the flowers in a spike are sometimes peloric. In *Euphrasia* and many species of *Veronica* the posterior sepal is suppressed. The form of the corolla shows great variety, depending on the length and breadth of the tube—which in *Veronica* is almost obsolete, while in foxglove it is large and almost bell-shaped—and the development of the limbs, which are spreading in *Veronica,* small and almost erect in figwort, or form a pair of closed lips as in *Linaria* and *Antirrhinum.* In *Verbascum* the five segments are almost equal, forming a nearly regular corolla; the approach to regularity in the corolla in *Verbascum* is associated with the presence of five fertile stamens, but the three posterior are generally larger than the two anterior. In *Veronica, Calceolaria* and other genera only two stamens are present. Honey is secreted by a disk surrounding the base of the ovary or by special nectaries below it. *Verbascum* and *Veronica* with a short-tubed corolla represent an open type of flower with more exposed nectar; in foxglove the honey is at the base of the long tube, and a bee crawling to reach it will rub with its back the anthers or stigmas which are placed on the upper side of the bell. The closed flowers of *Linaria* and *Antirrhinum* can be visited only by insects strong enough to separate the lips.

The fruit is generally a capsule surrounded at the base, or sometimes as in yellow-rattle (*Rhinanthus*) enveloped in the persistent calyx; it opens by two or four valves, or, as in *Antirrhinum,* by pores. Occasionally it is a berry. In *Linaria Cymbalaria* the fruit becomes buried by the stalks bending downwards when ripe.

The family is divided into tribes by characters derived from the number of fertile stamens present and the form of the corolla. It is well represented in Britain by 13 genera, viz., *Verbascum* (mullein), *Linaria* (toad-flax), *Antirrhinum* (snapdragon), *Scrophularia* (figwort), *Limosella, Sibthorpia, Digitalis* (foxglove), *Veronica* (speedwell), *Bartsia, Euphrasia* (eyebright), *Rhinanthus* (yellow-rattle), *Pedicularis* (louse-wort) and *Melampyrum* (cow-wheat). The best known representatives in North America are *Verbascum* (mullein), *Pentstemon* (beard-tongue), *Mimulus* (monkey-flower), *Veronica* (speedwell), *Gerardia, Castilleja* (painted cup), and *Pedicularis* (louse-wort). Common in cultivation are European species of *Antirrhinum* (snapdragon), *Digitalis* (foxglove), and *Linaria* (toad-flax). Several genera are well known in gardens; such are *Calceolaria, Collinsia, Pentstemon* and *Mimulus* (musk).

SCRUB-BIRD, the name applied to species of an Australian genus of birds and especially to *Atrichornis clamosa.* This bird is brown above, each feather barred with a darker shade; the throat and belly are reddish-white and there is a black patch on the throat; the flanks are brown. It inhabits the thickest "scrub" and the males are noisy and imitative. A second species, *A. rufescens,* from New South Wales, is brown all over. They form the family *Atrichornithidae* of the perching birds (Passeres).

SCRUTIN DE LISTE, a system of election of national representatives by which the electors of a department vote for all the deputies to be elected in that department, comparable to the "general ticket" in the United States (Fr. *scrutin,* voting by ballot, and *liste,* a list). It is distinguished from the *scrutin d'arrondissement,* under which the electors in each arrondissement vote only for the deputy to be elected in it. *See* REPRESENTATION.

SCRUTINY, careful examination or enquiry. The word is specifically applied in the early Church to the examination of the catechumens or those under instruction in the faith. They were taught the creed and the Lord's Prayer, examined therein and exorcized prior to baptism. Scrutiny also indicates a method of electing a pope in the Roman Catholic Church, in contradistinction to two other methods, acclamation and accession. (*See* CONCLAVE.) In the law of elections, scrutiny is the careful examination of votes cast after the unsuccessful candidate has lodged a petition claiming the seat, and alleging that he has the majority of legal votes.

SCUDÉRY, GEORGES DE (1601–1667), French writer, was born at Havre, on Aug. 22, 1601. He first served in the army but conceived a fancy for literature before he was thirty, and during the whole of the middle of the century he was one of the most characteristic figures of Paris. He gained the favour of Richelieu by his opposition to Corneille. He wrote a letter to the Academy criticizing the *Cid,* and his play, *L'Amour tyrannique* (1640), was patronized by the cardinal in opposition to Corneille. He was appointed governor of the fortress of Notre-Dame de la Garde, near Marseilles in 1643, and in 1650 he was elected to the Academy. During the troubles of the Fronde he was exiled to Normandy, where he made his fortune by a rich marriage. He was an industrious dramatist, but *L'Amour tyrannique* is practically the only piece among his numerous tragicomedies and pastorals that has escaped oblivion. His other most famous work was the epic of *Alaric* (1655). He lent his name to his sister's first romances, but did little beyond correcting the proofs. He died at Paris on May 14, 1667. Scudéry's swash-buckler affectations have been rather exaggerated by literary gossip and tradition. Although possibly not quite sane, he had some poetical power, a fervent love of literature, a high sense of honour and of friendship.

SCUDÉRY, MADELEINE DE (1607–1701), French novelist, sister of Georges de Scudéry (*q.v.*), established herself in Paris with her brother. She was at once admitted to the Rambouillet coterie, afterwards established a *salon* of her own under the title of the *Société du samedi,* and for the last half of the 17th century, under the pseudonym of "Sapho" or her own name, was acknowledged as the first blue-stocking of France and of the world. She formed with Pellisson a close friendship only terminated by his death in 1693. Her lengthy novels, such as *Artamène, ou le Grand Cyrus* (10 vols. 1648–1653), *Clélie* (10 vols. 1654–1661), *Ibrahim, ou l'illustre Bassa* (4 vols. 1661), *Almahide, ou l'esclave reine* (8 vols. 1661–1663) were the delight of all Europe,

including persons of the wit and sense of Madame de Sévigné. With classical or Oriental personages for nominal heroes and heroines, the whole language and action are taken from the fashionable ideas of the time, and the personages can be identified either really or colourably with Mademoiselle de Scudéry's contemporaries. In *Clélie,* Herminius represents Paul Pellisson; Scaurus and Lyriane were Paul Scarron and his wife (afterwards Mme. de Maintenon); and in the description of Sapho in vol. x. of *Le Grand Cyrus* the author paints herself. It is in *Clélie* that the famous Carte de Tendre appeared, a description of an Arcadia, where the river of Inclination waters the villages of Billet Doux, Petits Soins and so forth. The interminable length of the stories is made out by endless conversations and, as far as incidents go, chiefly by successive abductions of the heroines, conceived and related in the most decorous spirit, for Mademoiselle de Scudéry is nothing if not decorous.

In that early day of the novel prolixity did not repel. "Sapho" had really studied mankind in her contemporaries and knew how to analyse and describe their characters with fidelity and point. Moreover her novels had the interest always attaching to the *roman à clef.* She was a real mistress of dialogue. She had a distinct vocation as a pedagogue, and is compared by Sainte-Beuve to Mme. de Genlis. She could moralize—a favourite employment of the time—with sense and propriety. Though she was incapable of the exquisite prose of Mme. de Sévigné and some others of her contemporaries, her purely literary merits were considerable. Madeleine survived her brother more than thirty years, and in her later days published numerous volumes of conversations, to a great extent extracted from her novels, thus forming a kind of anthology of her work. She outlived her vogue to some extent, but retained a circle of friends to whom she was always the "incomparable Sapho." She died on June 2, 1701.

Her *Life and Correspondence* were published at Paris by MM. Rathery and Boutron in 1873. An amusing sketch of her is to be found in vol. iv. of Sainte-Beuve's *Causeries du lundi.* Georges de Scudéry is sketched by Théophile Gautier in his *Grotesques. See* also V. Cousin, *La Société française au XVIIe siècle,* vol. ii.

SCULL, a light oar with blade more concave than the ordinary racing oar and with shorter helm, thus allowing the user to hold one in each hand. *See* ROWING; BOAT.

SCULPTURE, the art of representing observed or imagined objects in solid materials and in three dimensions. The field of sculpture is so vast that it cannot be conveniently covered in a single article. It has therefore been divided into a number of parts incorporated under various subjects.

For the technique of sculpture, *see* SCULPTURE TECHNIQUE: *Modelling; Casting and Finishing; Terra-Cotta; Stone Carving; Wood Carving; Plaster Casting. See* also GEM; NUMISMATICS; IVORY CARVING; WOOD CARVING; STONE CARVING; SILVERSMITHS' AND GOLDSMITHS' WORK. For additional history of Sculpture, *see* EGYPT: *Art and Archaeology;* GREEK ART; ROMAN ART; BYZANTINE ART; RENAISSANCE ART; GOTHIC ART. There are also independent articles, such as CHINESE SCULPTURE and JAPANESE SCULPTURE, as well as sections under INDIAN AND SINHALESE ART AND ARCHAEOLOGY; TIBETAN ART; MEXICO; NEGRO, etc. Following this general treatise, the various uses of sculpture are given in special articles under SCULPTURE: *Monumental; Garden; Portrait; Architectural; Decorative.*

For the work of individual sculptors the following names may be referred to: PHEIDIAS, PRAXITELES, DONATELLO, MICHELANGELO, BERNINI, GOUJON, CANOVA, RODIN.

HISTORY

Undoubtedly the beginnings of sculpture may be explained by that spontaneous delight which all men find in the imitation of natural objects. Sculpture would seem to be almost inevitably conceived as a realistic art, since it offers us, not appearances, like painting, but actual forms reproduced from nature and placed, like nature's forms, in space. Yet the power of sculpture to embody also an abstract beauty, like music or architecture, seems to have been felt at a very early date. The use of sculpture for the decoration of objects, such as the bone handles of weapons, in which imitated natural forms had to be fitted to the contours of geometric forms, may have led to the discovery of that arranged beauty that arises from a rhythmic disposition of line and mass. Purely representative sculpture, cut into the wall of a cave or carved from a tree-trunk, assumed immediately a corresponding tendency towards the creation of abstract harmonies. Composition, which implies a conscious selection and arrangement of observed objects and demands an adjustment of nature to fit an assigned space, became a necessary part of artistic effort. That idealization of nature, which selects from her seeming chaos laws which are in harmony with his own needs and desires, prompted the artist to insist upon those laws in his descriptive art, which was thus diverted from its original intent—the literal rendering of natural form. Throughout its history, sculpture has thus offered two kinds of beauty: the sensuous beauty of imitated natural forms and the imagined or religious beauty of natural forms made harmonious with man's spiritual needs.

EGYPT

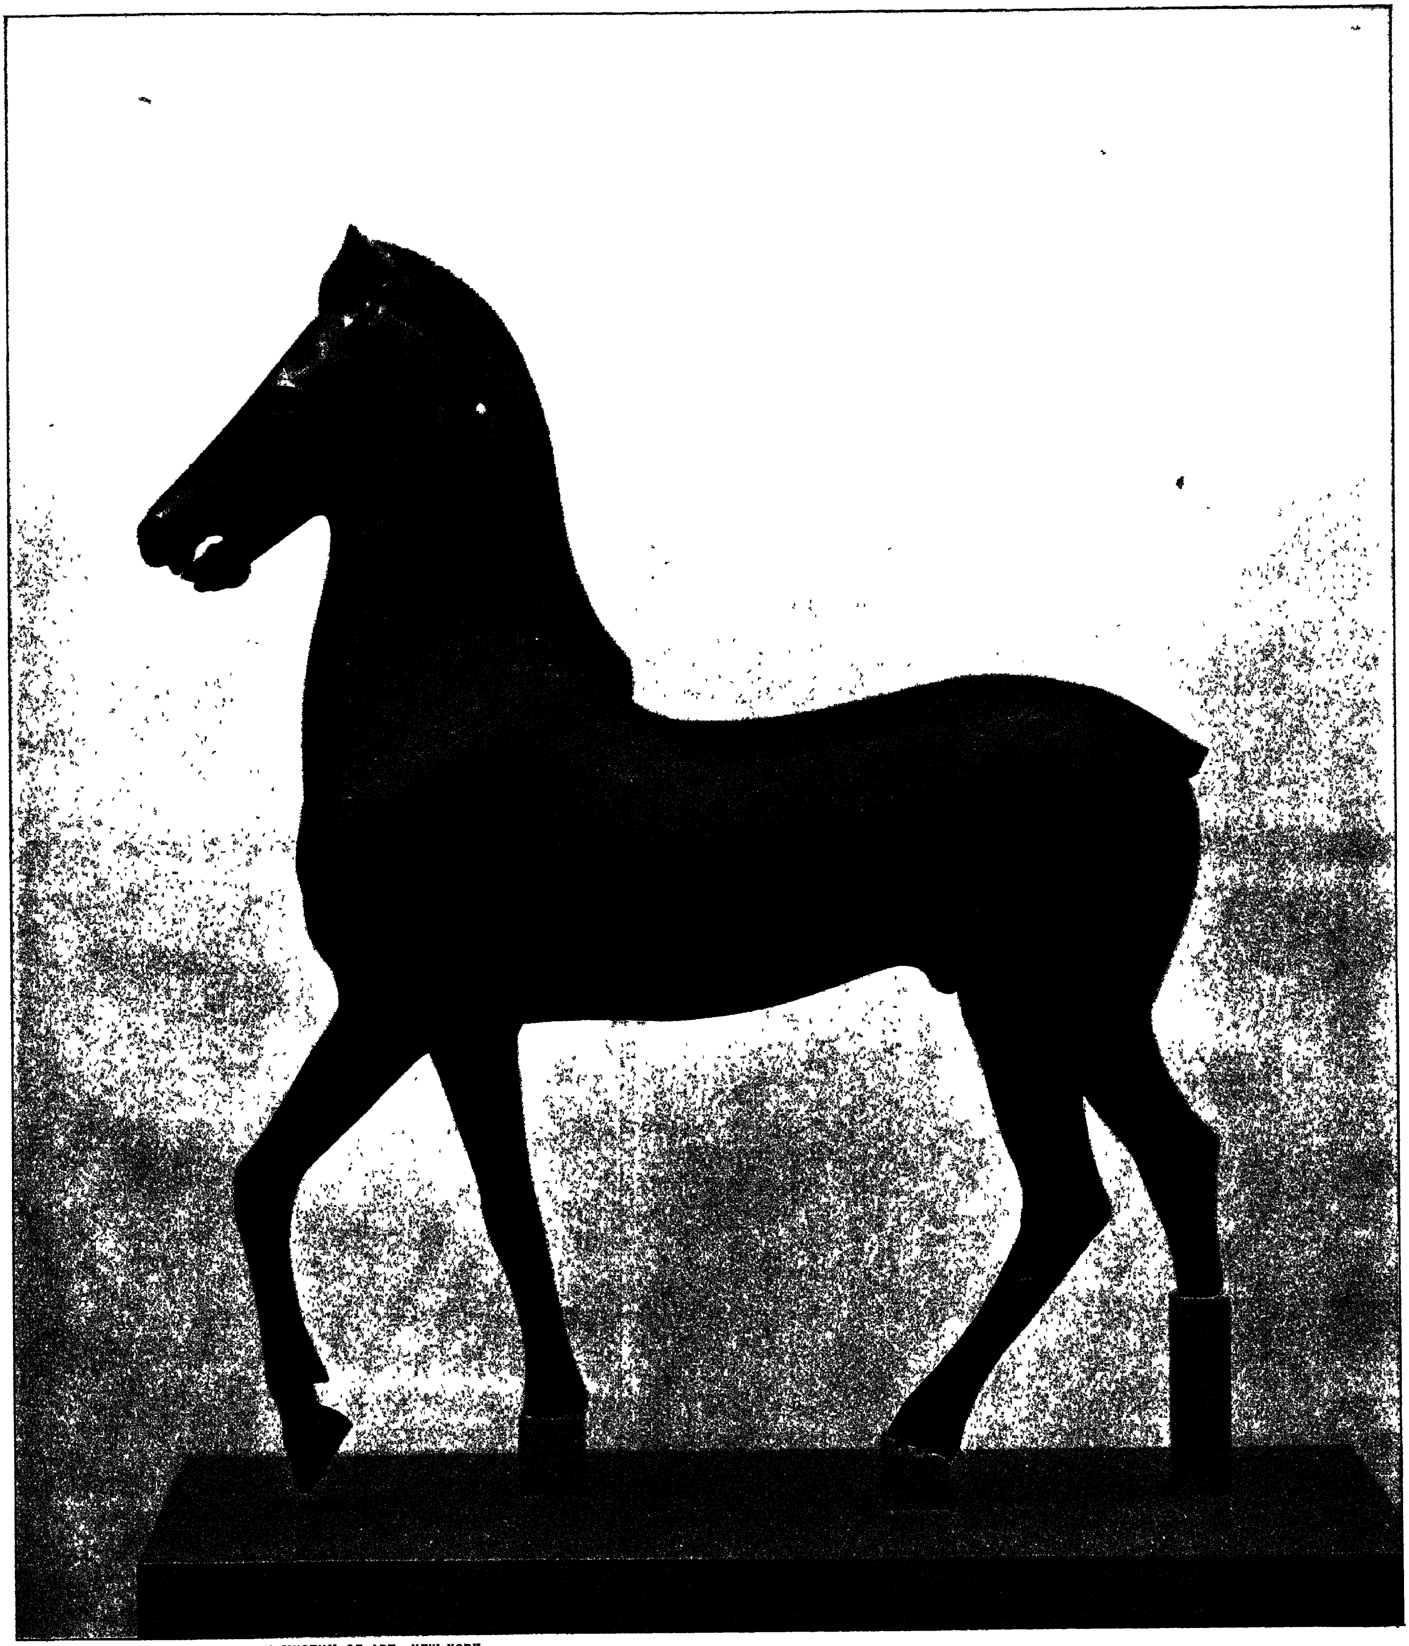
This dual rôle of sculpture is illustrated in the art of Egypt. In the decorative sculpture of Egypt, natural forms, or forms derived from nature, are oftentimes perfectly adjusted, through elimination or arrangement of parts, to the shape and material, the structure and function of furniture, weapons, fabrics, and architecture. The world of chiselled forms which peoples the tombs of the Nile valley, although ritualistic and useful in its purpose and hidden for ever from the eyes of men, shows a persistent search for harmony in arrangement and for the idealization of nature. The power of these abstractions is most evident in the great seated statues of the Pharaohs, which are neither decorations nor illustrations, but monuments. The compact and definite forms, the economy of detail, the great scale and the emphasis upon the inner structure of the body, endow these heroic figures with the architectonic grandeur of abstract forms; and the characterization of the figure, ignoring physical peculiarities to insist upon spiritual realities—upon the dignity, reserve, and power of sovereignty—informs them with the majesty they were intended to celebrate.

Egyptian sculpture illustrates also the way in which the reproduction of nature is limited, in sculpture, by artistic or social conventions. Sculpture, in spite of its objectivity is necessarily a conventional art, limited in range by the need for equilibrium and by the nature of its materials. Conventions, arising in primitive times from inadequacy of technique, or invented by some artist as an expedient for the realization in stone of that pattern which he perceives in nature, are continually being crystallized into precedents or even into social or religious laws. From the repetition of conventions there arise traditions which interpose themselves between the individual artist and nature. The monotony of the sculpture of Egypt, which for forty centuries observes the same iron convention, is perhaps its most amazing characteristic; yet there is no sculptor, except the first sculptor, who has not felt to some extent the generalizing influence of tradition. Of all the arts, sculpture is, excepting only architecture, the most traditional.

GREECE

The idealization of nature and of man, which was an essential part of the Hellenic religion, encouraged the Greek sculptor to escape from the conventions of Egypt, and to discover, in nature, a nobler pattern for the human body. In Greece, religion, far from despising nature, gave her sanction to that passion for nature, to that persistent and penetrating search for the secrets of nature's beauty, which the greatest Hellenic sculpture expresses. From the investigation of appearances the Greek sculptor proceeded to the investigation of the laws of structure and of form, to the architecture of the human body. A simplification of planes, a lucid relationship among the masses and contours, a harmonious direction of line and shadow, are the result of this analysis. The serene beauty of the 5th century gods arises directly from the imposition of these qualities upon forms that are also sensuously beautiful.

In the 4th century, when an interest in individual beauty sup-



BY COURTESY OF THE METROPOLITAN MUSEUM OF ART, NEW YORK

GREEK BRONZE, BELIEVED TO BE OF ATTIC OR SOUTH ITALIAN ORIGIN

The statuette, 15 13/16 inches in height and 14¼ in length, is believed to have been made about 470 B.C. Although there is uncertainty about the identity of the artist, the beauty and grace of the conception of the design point to the possible workmanship of Calamis, a well-known Athenian sculptor. Indeed, there is considerable basis for the conjecture that this statuette is a part of a miniature model of the charioteer group which Calamis was commissioned to execute by the Syracusan tyrant Deimonides. The tail, parts of the legs and one ear, and the eyes, which may have been inlaid, are missing. It is cast solid, weighing 25½ pounds

planted the religious exaltation of the Age of Pericles, these metaphysical qualities are less evident in sculpture. The gods lose their heroic detachment, their moral calm, as the artist develops a more descriptive technique. The planes which bound their bodies become less rigid and less definite as the artist searches out the nuances of light and shadow that pass over them. The action of inward forces becomes hidden under a clothing of soft and tremulous flesh.

After Alexander Greek sculpture departs still farther from the rigorous "architecture" of the 5th century gods. Life is reproduced with greater and greater actuality. Detail is elaborated; movement, expressed in the effort of muscles or the sweep of draperies, and emotion, often violent and exaggerated, is insisted upon. Allegory and narrative rather than form become the preoccupations of the sculptor. The Greek artist, who had discovered in the human body a pattern of divinity, ends as a story-teller in whose art this pattern persists only as a system of elegant eliminations, a canon of correct proportions.

THE ROMAN EMPIRE

Rome, after the 1st century B.C., became the chief patron of the realistic sculpture of Greece. The production of copies and imitations for the Roman market amounted almost to an industry in Antioch, Alexandria, and in certain cities in Asia Minor. Precedent and convention necessarily take the place of nature and architecture under these conditions as the determining element in the art of sculpture. The spirit of the Orient was increasingly felt, dissolving the Greek forms under an opulence of ornamental motives; and when, in the 2nd and 3rd centuries, Christianity and monasticism robbed the sculptor of the patronage of the temples, the human body gradually ceased to play its ennobling part in his art. The Hellenic types remained. The narratives of the Old and New Testament, the martyrdoms of the Saints, are illustrated by a rearrangement of Alexandrine groups. Hermes, the Ram-bearer, becomes the Good Shepherd; the *genre* fisherman becomes Christ, the Fisher of Men. But these are reduced in scale, oftentimes little more than the decorative detail of wall-panel or sarcophagus, and charged with a ritualistic meaning which obscures nature and renders her unnecessary.

In Rome itself a parallel transformation took place, although the Greek tradition found there a more virile continuation than in the East. The imagination of Rome, like that of the East, was captured by the realism of the art of the Age of Alexander rather than by the architectonic beauty of Athenian art, but in her commemorative monuments, such as the Arch of Titus and the Column of Trajan, the episodic style of Alexandria is given a wider range and a more vigorous technique than is found elsewhere. Sculpture, on these structures, is a purely pictorial art. Intent on an illusionist treatment of nature and of events the sculptor seldom permits the monumental harmonies to invade his work. In Rome, the rendering of foliated ornament attained a perfect balance between nature and convention not excelled except in the Renaissance decoration of the 15th century; the art of realistic portraiture reached a technical perfection; and at times, as in the Ara Pacis Augustae, the Hellenistic precedents of dignity and grace in the rendering of draperies and of flesh are exquisitely revived. But in Rome, as in the East, the form-giving rôle of sculpture is gradually forgotten.

ROMANESQUE SCULPTURE

It was not until the 11th century that sculpture became once more a monumental art. In the Romanesque monasteries, which covered Western Europe, sculpture, being made once more subordinate to architecture in the decoration of cloister and abbey doorway, began a fresh development which carried it from archaic beginnings to a superb culmination in the sculptural ensembles of the 13th century cathedrals.

The basis for this new sculpture was the Christian iconography of the East and of Rome, derived as we have seen from a somewhat distant Hellenic tradition. The Romanesque sculptor had to learn anew the technique of his craft but he had for his model the forms of an art already sophisticated and even decadent. The theocratic spirit of the age turned him from the observation of natural or human beauty. Preoccupied with spirit and not with form, he could not evolve his Christ, like the Hellenic Apollo, from a naked athlete. The Christian sculptor began with symbols —symbols made sacrosanct by authority and usage. His reliefs, cut in the tympana of abbey portals or moulded on the panels of bronze doors, repeat the types, the proportions, even the stylistic treatment—the low relief, the concentric folds and clinging drapery, the colour and gold—of a Byzantine miniature or ivory-carving.

But ivory carvings and miniatures cannot be fitted, without some modifications, into an architectural scheme. To do that a rearrangement of their figures, a redistribution of shadow and emphasis, and an enlargement of scale are necessary. Figures placed in the semi-circular tympanum of a doorway demand a balanced composition in which a central figure is made dominant and all the lines and shadows made to bend in harmony with the wide arch over them. Figures chiselled on a lintel demand a regular and rectilinear arrangement, free from deep shadow and bent line; figures placed on the splays of doorways must stand rigidly upright and be free of gesture or a too marked individuality; and figures cut into a capital must follow, in a symmetrical, flower-like arrangement, the warped surfaces which are transitional between shaft and arch. In this way the Byzantine forms, already abstract, suffered in the hands of the monastic builders a further abstraction; they are transformed into architecture.

GOTHIC SCULPTURE

The monastic carvings formed the basis from which the communes of northern France developed the superb sculptural art of the 13th, 14th, and 15th centuries. The great cathedrals demanded sculpture in order that the abstract and mechanical rhythms of their architecture might be informed with some measure of life and of sensual beauty. No doubt some of this sculpture, like that of the monasteries, was doctrinal, or even didactic in origin. Symbolism, an "algebra of art," was certainly an important source of inspiration wherever the Church controlled the design. But these were not the primary impulses from which Gothic art sprung. Those impulses lay very deep in the emotional life of the time. Gothic sculpture, like Gothic architecture, is the concrete expression of that great wave of joyousness and health, of spiritual unity and heroic exaltation that was born with the rise of the great communes. It is an art, not of dogma, but of a natural and human society. It expresses, in its great period, the collective soul of a Europe that for a moment found in an exalted faith an escape from tyranny and despair.

13th Century.—The remarkable characteristic of 13th century sculpture is its recovery of the plastic sense. Romanesque sculpture, essentially an art of relief and of ornament, remained, in the monasteries, almost wholly decorative and symbolic in character; but the patronage that created Gothic art—that of the communes of northern France—desired almost from the beginning a sculpture of three dimensions. At Chartres, at Bourges, and at the Abbey of St. Denis we find as early as the third quarter of the 12th century, figures cut in the round, true statues, which announce unmistakably their character as stone monuments. Rigid in contour and with the forms revealed by definite clear planes, surrounded by light and space, the Gothic figures of the 13th century possess in a remarkable degree a quality of beauty that is unmistakably glyptic.

Even more remarkable is the humanization of this sculpture. When the solid architecture of the first cathedrals had imposed simplicity and breadth, concreteness and balance, upon the Romanesque forms, the free spirit of the communes re-endowed them with natural beauty. In the great portals of the 13th century cathedrals, a stone population, imprisoned still in vast architectural frames, takes on gradually the aspect of reality, as the sculptor turns from symbolic pictures to nature. The bodily semblances of men and women emerge from the shaft-like forms that stand along the doorways; they assume attitudes of life, turning the head, raising an arm, planting the feet firmly upon the ground. Their angular planes soften into effects of warmth and

energy; their draperies lose their geometric stiffness to hang in graceful folds that reveal the action of the bodies beneath; and their faces, still ideal and generalized, assume a physiognomy and expressiveness that interpret character and mind. An equilibrium between architecture and nature is once more established. As in the pediments of the Parthenon and the Temple of the Olympian Zeus, an enframement of noble architecture imposes order and a mystic beauty upon an ensemble of forms which are at once symbolic and human.

This new art had to be developed step by step from experimental beginnings. It grows from archaism to scientific mastery, in a manner which curiously parallels the development of Greek sculpture. The earliest statues, like those from Corbeil (now at St. Denis) or in the Porte Royale of Chartres, seem to have been cut from columns—as though the sculptor had merely revealed, by the removal of an outside covering, the living forms imprisoned within the shaft. Rigid and compact in form, these statues have the "frontality" of primitive Greece. Their angular immobile bodies are wrapped in thin draperies whose parallel folds are delicately incised. The gestures are stiff and awkward. The faces, with prominent eyes, have the curious ironic smile of archaic art. Like the draped figures erected on the Acropolis in the 6th century, the "kings and queens" of Chartres charm us with a naïve and natural technique, quite free from the austere conventionality of Romanesque carvings. Ranged in their architectural enframement, they possess also a tense and mystic dignity—like apparitions, existing in a world of dreams.

Less than one hundred years separate these archaic beginnings from the superb culmination of Gothic sculpture in the portals of Reims and Amiens. The rapid construction of the great cathedrals was paralleled by the development of a sculpture that was amazingly profuse and vigorous. The Greek miracle was repeated; the French sculptor in two generations reconquered all that Rome and Byzantium had lost. The innumerable figures of saints and prophets that fill the doorways of the cathedrals are studied from nature and not from Byzantine iconography. Endowed with humanity and with life, these figures are nevertheless treated with a breadth and simplicity altogether consonant with the nobility of their architectural enframement. The draperies, modelled in such a way as to reveal the form and action of the body, are at once gracious and solemn; the gestures and attitudes, while wholly unconstrained and expressive, are yet free from any violence or agitation that might disturb the repose of the geometric design; and the faces, although living and individual, have almost invariably that grave passivity that is most suitable to an architectural environment. The solemn company of saints or prophets stand, as they might stand in Heaven, on either side of the figure of Christ, or of His Mother, who is surrounded by a choir of angelic figures, ranged in the orders of the vault. In the tympanum a rich embroidery of reliefs explains in pictorial imagery some story—the Redemption, the Resurrection—full of symbolic meaning. The whole is a transcendent vision, half history, half prophecy, revealing the completeness and order and grandeur of that universe which the mediaeval theologian, himself an artist, had envisaged.

The notable qualities of these great ensembles are the perfect union of sculpture and architecture—of nature and mathematics—and the dependence of each part upon the character of the whole. The beauty of nature enters here only to be subdued to the spiritual harmonies which control the design.

The figures of the martyrs in the south transept portal of Chartres (*c.* 1220) are excellent examples of early 13th century figure sculptures. The bodies, enveloped in compact masses of drapery which prevent the slightest articulation of leg or torso, are cut from cylinders of stone. The feet are planted firmly on corbels sculptured with a symbol of martyrdom; the arms cling closely to the bodies; the erect heads bend only in the slightest degree to the right or left. The draperies are thinly incised and hang in studied parallel folds. What gives these figures beauty and spiritual power is the idealization of their faces and the part which they take in the vast ensemble about them. One feels in the transept portals of Chartres the unmistakable presence of a spiritual authority.

The figures of St. Theodore and St. George (*c.* 1240), also in the south portal of Chartres, illustrate the rapid technical advance that took place in the second quarter of the 13th century. These figures have little of the rigidity of the martyr figures standing beside them. The weight of the body, which bends a little to one side, is thrown upon one foot, and the forms of the legs and shoulders are indicated beneath the draperies which fall in more natural and much deeper folds. The elegance and dignity of these figures is paralleled in those of the right portal of the west façade of Amiens: *La Porte Mère-Dieu,* the first great doorway that is wholly Gothic in character. The natural ease of the postures and the grace of the draperies, especially in the figures of the women, endow these figures with charm without robbing them of their hieratic dignity. The central and left doorways at Notre-Dame, Paris, and the portals of Laon Cathedral, although much restored, are also fine examples of Gothic sculpture of the first half of the XIII. century; but undoubtedly the greatest achievement of this period is the central doorway of Amiens. This majestic portal, which has for its central figure the radiant *Beau Dieu* flanked by the ranged forms of the Disciples, most perfectly achieves the Gothic ideal: a celestial vision that brings within the compass of a single architectural design one of the noblest ensembles of form ever conceived by man.

The great portals of Reims contain many examples of early 13th century sculptures—the *Abraham,* for example, and the *St. John the Baptist* on the right doorway of the western façade; but the greater number of the figures, as well as the sumptuous character of the whole, are more characteristic of the last half of the century. After 1260, the architecture of the doorways holds the statues which people them less firmly in its embrace. The curves of the bodies increase; their contours and planes become less regular and less definite; the draperies, shot with deep shadows, assume a picturesqueness that tends to destroy their plastic unity. The faces are less generalized. A sweet humanity softens the religious austerity of saints and angels. Sometimes, as in the central doorway of the west façade, they turn towards each other to enact some simple drama, and sometimes—as in the *St. Elizabeth*—we discover a modelling that seems obviously imitated from some Hellenic example. Greece is never far distant from these 13th century figures. The Greek spirit, or a spirit akin to the Greek, pervades them even when there is no suggestion of Greek technique. Standing at the threshold of the 14th century, when realism is beginning her successful conquest of architecture, the figures of Reims have that tense and somewhat nervous beauty that seems to foretell the profound change that is taking place in Christian thought.

14th Century.—The perfect balance between mathematics and nature lasted only a moment. By the first quarter of the 14th century, when the cathedral-building impulse was dying, when the making of shrines, of tombs, of ecclesiastic furniture drew the sculptor from his work in the great portals, the architectural quality had already lost its dominance in his modelled forms. The figures in the jambs of the doorways begin to sway, to bend, to make gestures no longer confined within the architectural frame. No longer generalized in type, they become individuals, rendered oftentimes with an actuality of detail and of expression that approaches portraiture. Their draperies, falling in naturalistic folds, are arranged ingeniously for effects of chiaroscuro and of pattern in which the structural line is progressively ignored. The groups in the tympani, the seriated figures in the orders of the arches and along the lintels abandon their simplicity for a luxury of detail and for pictorial truthfulness. Their number is multiplied; accessories, details, settings are elaborated; and the narrative, rather than the symbolic meaning, is insisted upon. The foliated forms of flower and leaf spring from the cathedral stones; birds, animals, landscapes appear; contemporary costume and contemporary personalities are depicted. From the observed universe about him the sculptor creates a new iconography in which types of living people replace the types which tradition had established and in which there are substituted, for the doctrinal scenes of monastic art, scenes such as the Coronation, the Entombment, the

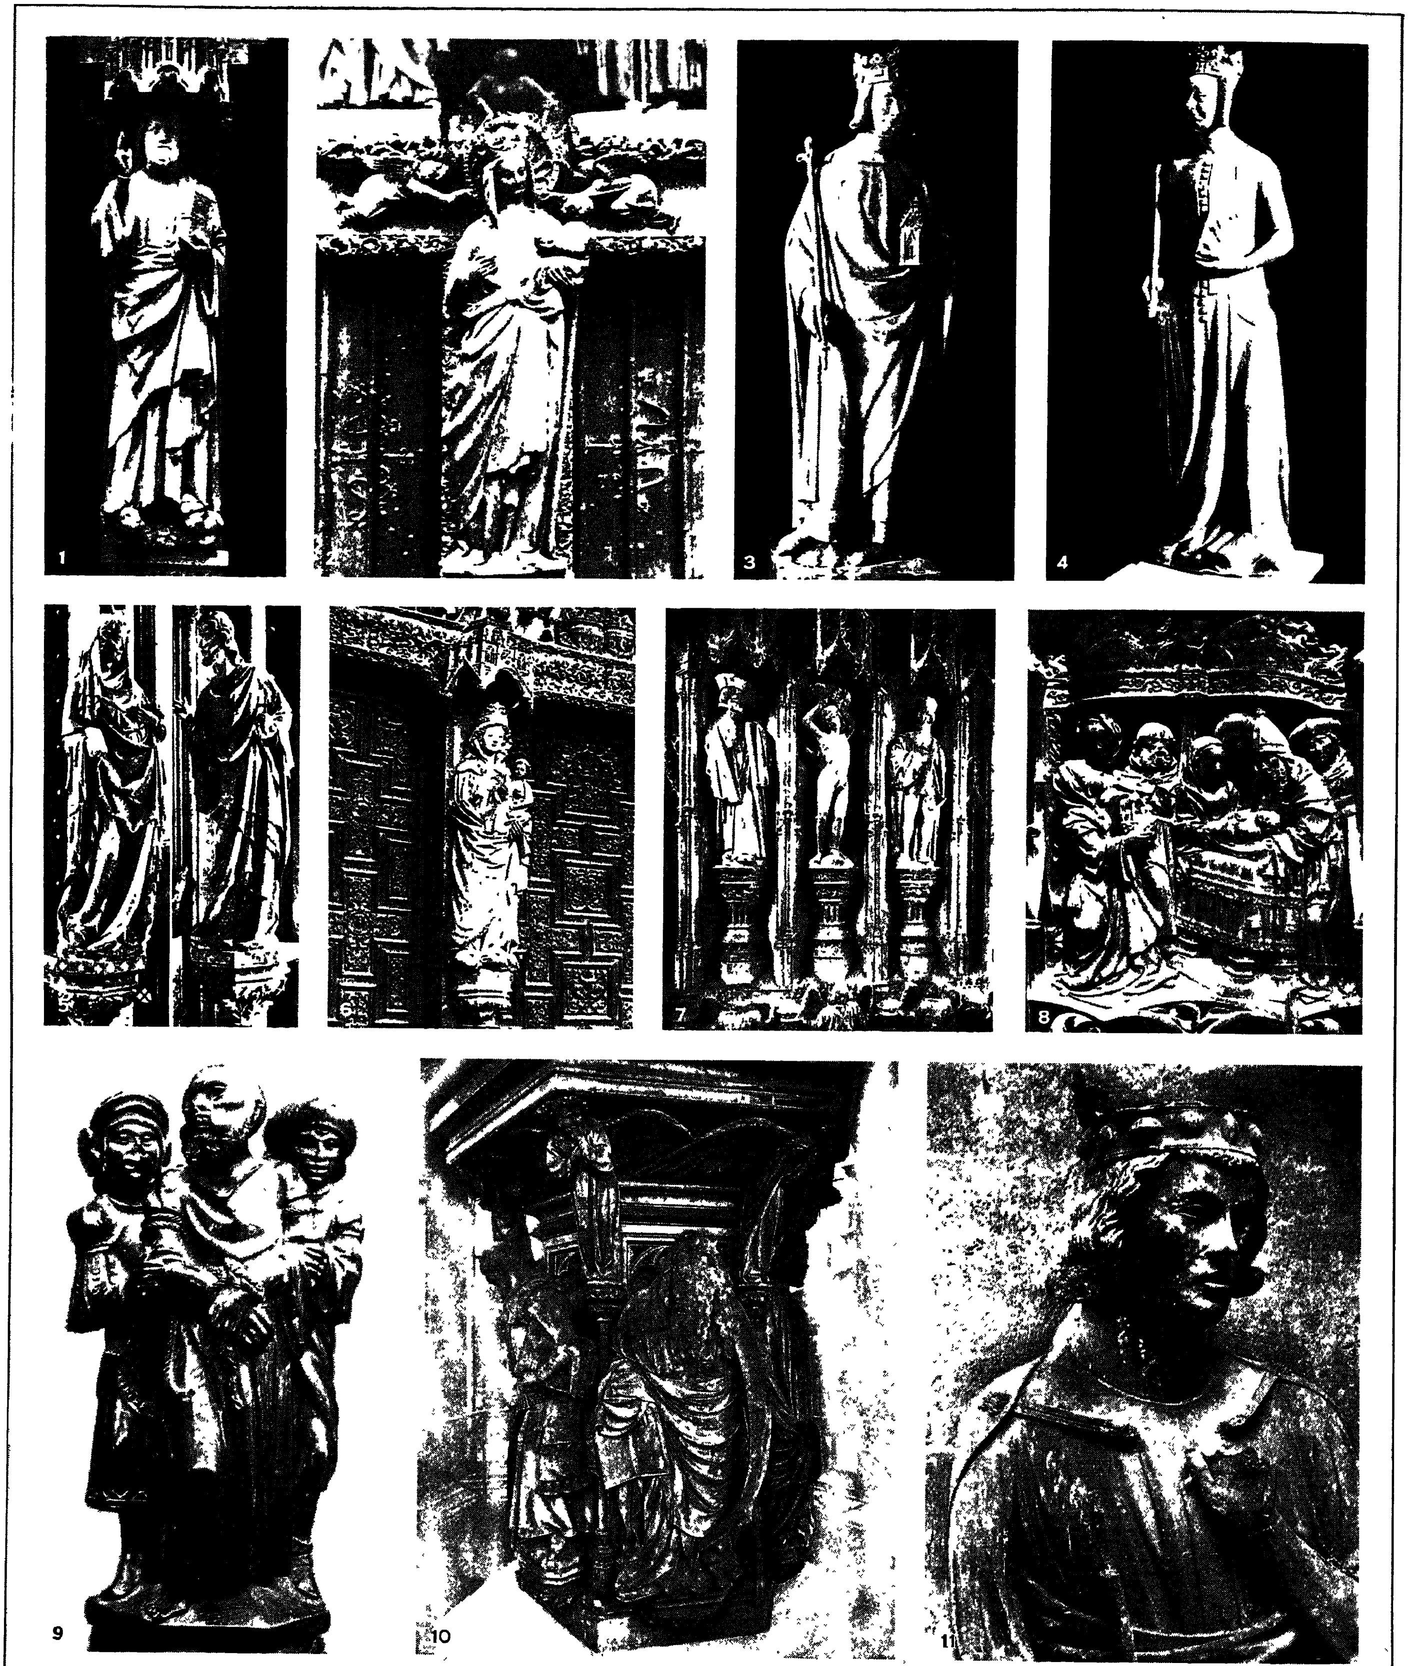
GOTHIC ARCHITECTURAL SCULPTURE

1. Tympanum above the left portal of the façade of Notre Dame, representing the entombment of Christ and coronation of the Virgin, 13th century
2. Bas relief from the Château de la Ferté-Milon, 14th century
3. Right side of the central door, North Porch, Chartres cathedral, France. The figures, admirable examples of 13th century northern France Gothic, represent Isaiah, Jeremiah, Simeon with the Child Jesus in his arms, John the Baptist, and Peter
4. Statue of King Solomon and the Queen of Sheba, formerly at Corbeil, now at St. Denis
5. Statues of Edwy (Eadwig) and Edward the Martyr, kings of England, on the front of Wells Cathedral, part of a group of ten kings and princes in an exterior decoration scheme of statuary comprising 180 figures, many life size, executed in polychromed stone. First half of the 13th century

SCULPTURE



GOTHIC SCULPTURE

1. Statue of Christ (*Beau Dieu*) on central portal of Amiens cathedral, 13th century. 2. *La Vièrge Dorée* on south transept portal of Amiens cathedral. 3. Charles V. of France, 14th century, portrait statue. In the Louvre. 4. Jeanne de Bourbon (d. 1378) at St. Denis. 5. Mary and Christ. German. 6. *Nuestra Señora la Blanca* on the portal of the south transept of Leon cathedral, 14th century. 7. St. Sebastian, in the Chapel of Henry VII. (built 1502–20) in Westminster Abbey. 8. One of 400 carvings on the choir stalls of Amiens cathedral, 1508–19. 9. Wood carving, Amiens cathedral. 10. "Moses' Well," pedestal by Claus Sluter and Claus de Werver, 15th century. 11. St. Louis, Reims cathedral

Scenes of the Passion, which are expressive of human suffering and of human aspirations.

The sculpture of the 13th century was international in character, all Europe having turned to France for inspiration and guidance. The fine sculptures of the cathedrals at Bamberg and of Strasbourg, for example, are the work of men who must have been intimately familiar with the sculptures of Reims and Chartres. The famous tympanum of the Hospital of St. John, in Bruges, is a direct imitation of French work. The figures on the towers of Wells (*c.* 1230) although displaying a tenderness that is unmistakably English in character were at least in part inspired by the Porte Royale of Chartres. At Burgos, the superb transept portals are probably the actual work of French artists, and the beautiful portal of the south transept of Leon Cathedral, although having many details that are Spanish—such as the *Neustra Senora la Blanca*—is essentially a reproduction of the north portal of Chartres.

In the 14th century, when the vitality of France was lessened by the Hundred Years' War, and when the growth of realism had led to a more studied observation of contemporaneous life, local schools became gradually more independent. Of these, the schools of Germany appear to have been the most vigorous. The architectural line disappears at an early period in Germany. Free and even sinuous attitudes, lively and expressive faces, and draperies which are richly and even extravagantly modelled are characteristic of her 14th century sculptures, produced in great abundance and charged oftentimes with a compelling vitality. The pillar-statues in the choir of Cologne Cathedral (1322–1330) are good examples of this art, too strongly individualized for architectural effectiveness but with an intensity of life that is analogous in feeling to the Baroque. The ornate west portal of the Minster of Thann and the corresponding portal of the historic church of St. Lorenz in Nuremberg (both about 1350) show the mastery of the German sculptor in the use of realistic anecdote to produce a sumptuous ornamentation.

Flanders and, towards the end of the century, Burgundy were centres of realistic art scarcely less important than Germany. The naturalism common to all Europe at this time was especially suited to the temper of Flanders. A national art developed rapidly there from the French base and before the end of the century the making of sculptures had become almost an industry in Tournai, in Bruges, and in Courtrai. A colloquial art, deriving its subject-matter from the life of the court, the merchant-class, and the mystery play, Flemish sculptures, soon attained a vast popularity throughout northern Europe. No longer associated with architecture and no longer intent on the expression of spiritual or even intellectual concepts the sculptor rapidly abandoned the simple and monumental harmonies of the 13th century. These qualities no doubt appeared to him as limitations in technique. His own skill was oftentimes amazing, a representational virtuosity which delights us with its sympathetic rendering of contemporary life. The mediaeval world, like ancient Egypt, lives before us in his innumerable carvings in which the scenes of sacred history take place in the familiar settings of a Flemish market-place or church and are enacted by bourgeois figures that embody the physiognomy, the costume, the manners and the postures of their day.

Effigies and the ornamentation of tombs, the vast retablos that fill the spaces behind the altars, the sanctuary enclosures and chapel screens, and the choir stalls, with canopy, arm-rests and misericordia, are the objects most congenial to this pictorial art. These furnished inexhaustible fields for the incomparable skill of the 14th century carver, who filled the cathedrals with sumptuous furniture in which his storied art is mingled with a vast intricacy of ornamental forms—of carved canopy and interlaced tracery, of cusped panel and flowered pinnacle. For this work, stone soon ceased to be the desirable medium. Bronze, for sepulchral images and for fonts, was used extensively in Flanders, especially in the *Ateliers* of Dinant. Terra-cotta was also extensively used, but wood was by far the most popular material. Easily worked into the narrative panels and groups—greatly reduced in scale from the monumental work of the earlier century—and easily transported, wood lent itself also to the elaborate enframements, the gilded and coloured ornament, which had now become the fashion.

In the middle of the 14th century this Flemish art invaded France whose taste already shared the tendency of Flanders towards realism and decorative elaboration. The serene radiance of the 13th century had disappeared, to be replaced by a gracious and ingenious beauty that is less exalted and less self-contained. An elegance of line, especially in the flowing draperies, a gentle sentiment in the expression of the features, and an amusing dexterity in the rendering of accessories distinguish these French figures which by the middle of the 14th century had renounced altogether their architectural stiffness. The devotional statues of the Virgin and Child, made in large numbers at this time, illustrate most clearly this transformed art. These elegant and tender figures, whose bending forms are clothed with graceful simple draperies, are often informed with a sweet and appealing humanity. The many portrait statues of the period, such as those of Charles V. and Jeanne de Bourbon, in the Louvre, share these winning qualities. But in the numerous anecdotal scenes, which embellish the sepulchres, the choir stalls and the retablos we see more obviously the influence of Flanders.

A colony of Flemish sculptors had settled in Paris towards the end of the 13th century. Their numbers and influence increased rapidly. The vast population of little carved figures, of *genre* scenes and narrative panels, the wealth of intricate ornament, the sumptuous colour and gilding that were created with increasing opulence of form in the French cathedrals were due, in part at least, to this Flemish influence which continued into the 15th century.

This Franco-Flemish art found its way into England. The thirty angels in the Angel Choir of Lincoln Cathedral are touched with French coquetry and Flemish pictorialism; and the apostles in the upper tiers of the Exeter façade are clearly of Flemish descent. In wood carving England rivalled every continental school; her choir-stalls, such as those at Chester, Ely and Gloucester are not equalled for technical excellence and realistic animation except perhaps in the stalls of Amiens and Toledo. Realism, and an extraordinary delight in technical virtuosity, were common to all of northern Europe, and although Flanders was the centre of this art, the schools of England, France and Germany maintained always an independent tradition. Spain, which also yielded to the taste for episode and decorative embroidery formed a wide field for Flemish and French craftsmen, who carved the vast screens around the cathedral *coro* with a luxury of reliefs that are at once homely and sumptuous.

15th Century.—In the first part of the 15th century, except in Burgundy, every trace of monumental form disappeared before the universal triumph of Flemish realism. Carved landscape and architecture and even perspective are introduced into the wealth of episodic scenes that fill the retablos, the tombs and the choir stalls and appear in increasing quantity on the panels of secular furniture as well. A pure pictorialism overcomes everywhere what was left of the plastic sense. The groups of figures, accurately reproduced from life, are arranged in pictorial compositions which are pervaded by an emotionalism, a violence of gesture, a distortion of features wholly inconsistent with plastic beauty. The postures and types of everyday life are untouched by idealism or even by sentiment in this commercial art which achieves at its best only an illustrative interest and decorative beauty. Wood is the almost universal material. A finish of high colour and gold gave to its intricate surfaces a sumptuousness that is sometimes oriental in quality.

In Burgundy this excessive realism was tempered by a certain dignity, a breadth of handling and at times distinction of treatment. The pomp and wealth of the court of Dijon, which after the Hundred Years' War eclipsed momentarily that of Paris, demanded an art less bourgeois than that of the commercial towns to the north. Burgundian art, essentially a continuation of the nobler French tradition, yields in many ways to the objectivity of Flanders and still more to the boldness and weight of Germany. In this art realistic attitudes, realistic physiognomies and draperies, are given an emotional power, lacking in most

realistic sculptures, by reason of their solid proportions, the vigorous handling of mass, the scale of and weight of their materials, and by breadth of treatment. A great amplitude of drapery, simple in mass and outline, with broad and deep folds oftentimes gives to the Burgundian figures an almost monumental dignity. The *Pedestal* built in the Carthusian monastery of Champmol, near Dijon, by Claus Sluter and Claus de Werve is a characteristic example of this solid art.

In France, where much good work was produced in spite of the military calamities, the Flemish style continued to be tempered by a Gallic restraint and charm. French draperies are more fluid and graceful, French groupings less agitated, faces more tender and serene. The relief over the door of the chapel at Amboise, for example, although having all the Flemish accessories of landscape and picture, is yet ennobled by a tender sentiment and a certain dignity of posture and of composition. The *Coronation of the Virgin*, at the chateau of Ferté-Milon, is another lovely example of late French sculpture, more simple and more sincerely felt than its contemporaries in Antwerp.

The Loire valley, a region most secure from the ravages of the English war, was the region in which the French spirit was most persistent. Towards the end of the century this spirit reasserts itself in other parts of France. For a moment, in that period known as the Détente, it is exhibited in sculptures that have a breadth and simplicity not realized in sculpture since the beginning of the 14th century. At this time the realistic figures of tombs and ecclesiastical furniture, although still in contemporary costume, assume a tranquillity of pose and treatment that lends great dignity to their sensuous and pictorial beauty. The Détente did not at any time approach the 13th century, for its forms are at no time truly sculptural or truly monumental, but it did create many appealing and poetic figures. Of these the *Vierge d'Olivet* by Michele Colombe (in the Louvre) and the statues from the *Tomb of Francis II. of Brittany* in Nantes Cathedral are superb examples.

Germany was prolific in sculpture during the 15th century. Grace and tenderness are less frequent in her art, in which an exaggeration of movement and of emotion becomes more and more pronounced. The love of pictorialism, of agitated complex draperies, and of dramatic attitudes that distinguishes the late Gothic of Germany have often led to a comparison with the Baroque to which it is certainly akin. An intensity of spiritual experience oftentimes underlies the nervous and formless panels, filled with tumultuous draperies and agonized faces.

Germany developed a great variety of local schools. Of these, the School of Nuremberg is the more dramatic and robust in style, that of Würzburg more lyric, and that of Swabia more infused with thought. In Bavaria, where stone was used as often as wood, a greater restraint tempers the realism of the time.

German sculptors found their way into Spain in the 15th century and worked there side by side with their Flemish colleagues. The huge wooden retablos of the Spanish cathedrals, covered with sculptural relief and rich polychrome carvings, offered splendid fields for their art, which was not, of course, unmodified by the Spanish taste for sumptuous ornament or the Moorish tradition of intricate patterning and perfect finish. The great retable at Toledo Cathedral is an example, as are also the choir-stalls of León; these are perhaps the most splendid ensembles of carved ornament in Europe.

Under this magnificent embroidery architecture was forgotten. Sculpture no longer existed as a monumental art. Gothic sculpture had completed the cycle that Hellenic sculpture had followed; her sculptors end, like those of Greece, as story-tellers and ornamentalists.

RENAISSANCE SCULPTURE

In Italy in the 15th century the growth of the scientific spirit, expressing itself in research and experiment, led to a renewed interest in classic sculpture. This sculpture, which was that of Latium rather than of Greece, revealed itself at first as little more than a new and more perfect realism than had been achieved by the Gothic carver. It offered besides a system of chiselled ornaments which comprised new and exquisite motives for the embellishment of architecture. Especially in the modelling of the nude figure and in the design and rendering of draperies the ancient statues embody a technique which seemed to the Italian sculptor the perfection of representational art. The Pisan sculptors, Nicolo d'Apulia and Giovanni Pisano, were among the first to restore to the figures of Christ and His Mother, and to scenes from the Bible, the proportions, attitudes, and accessories of the figures on Roman sarcophagi, and their example was widely imitated throughout Italy.

As men turned with growing enthusiasm to the study of the ancient civilizations a broader appreciation of antique sculpture followed. Beyond its exquisite imitation of nature, artists perceived the idealization, or interpretation, of nature. The Italian sculptor awoke to the breadth and dignity, the monumental beauty, which his own decorative and narrative art had lost. Antique art, which had revealed to him the beauty of the human body, revealed also the beauty of structural law, of the geometry of mass and shadow, and taught him to seize those subtle relationships in the world of form which architecture abstractly expresses.

The concise monumental style of Giotto—a painter with a sculptor's mind—first exhibited this broader aspect of classic art. Lorenzo Ghiberti (1378–1455) expresses in his nudes, in his gracious draperies, in the restraint and dignity of his pictorial reliefs, some understanding of the new ideal. Donatello (1385–1466) illustrates to us all the stages by which the antique revealed itself. The uncompromising realism of his first work, his delight in *genre* types, in the rendering of muscles, harsh features, and textures, is gradually penetrated by the ennobling influence of the antique. Roman motives such as dancing children and the nude, enter his art together with that ideal and generalized beauty and the monumental harmonies that Rome teaches him. Human beauty and human dignity become the themes of this art. Thought, rather than sentiment, is the quality that shines through it. His bronze *David*, in the Bargello, Florence; his *Judith*, also in Florence; and his *Gattamalata*, in Verona, are superb examples of that balance which he achieved between actual and abstract harmonies.

Antonio Pollaiuolo (1432–1498) and Andrea del Verrochio (1435–1488) were realists whose energetic work shows much less the influence of the classics. The *Herakles and Antaeus*, in the Bargello, Florence, by Pollaiuolo, shows this artist's interest in movement and in anatomy, and the fine *Colleoni Monument*, in Venice, by Verrochio is a superb embodiment of energy and power. Luca della Robbia (1399–1482) and Andrea della Robbia (1435–1525) were decorators whose lovely ornament and devotional sentiment are often touched with antique serenity. Mina da Fiesole (1431–1484) and Desiderio da Settignano (1428–1464) were also decorators to whose gracious styles the classic motives were most congenial.

All of these were Florentines, but the new movement in sculpture was not confined to Florence. The Venetian sculptor Antonio Rizzo (died 1499), although essentially mediaeval, exemplifies in his nudes and his draperies a growing understanding of the classic spirit. In Venice also the Lombardi (Pietro and his sons Antonio and Tullio) developed an exquisite style of Renaissance ornament, which was, in technique at least, equalled by the work of Giovanni Antonio Amadeo (1447–1522) and his assistants at the Certosa of Pavia. The greatest sculptor, outside of Florence, was Jacopo della Quercia (1373–1438), a master of the nude, whose fine reliefs, set about the portals of San Petronio, in Bologna, anticipate in their energy the later figures of Michelangelo.

Michelangelo was without doubt the greatest sculptor of the Renaissance. His work, which was traditional and yet individual, derives its form and its technique from the classic and yet is full of an intensity of feeling that belong only to himself and to his own day. His heroic nudes express profoundly the pathos and futility of man's life; yet, while they speak a philosophic language, they embody also a physical beauty that is even more eloquent. The *Captive*, in the Louvre, most perfectly realizes these qualities, but they are present also in the marvellous figures

SCULPTURE IN ITALY AND FRANCE FROM THE 13TH TO THE 14TH CENTURY

1. "Madonna and Child," the earliest known work of Giovanni Pisano (1250–1320), a forerunner of the Gothic in Italy. In the Campo Santo, Pisa
2. "Creation of Eve" by Jacopo della Quercia (1371–1438), Italian; on the door of the Baptistry, Bologna
3. "David" by Donatello, Italian sculptor (1386–1466); the first nude statue of the Renaissance, executed in bronze about 1430 during the artist's classic period
4. "Herakles and Antaeus," a bronze statuette by Antonia Pollaiuolo (1432–98), Italian realist. In the Bargello, Florence
5. "Seated Moses" by Michelangelo (1475–1564); designed between 1513 and 1516 for the mausoleum of Pope Julius; now in the church of S. Pietro in Vincoli, Rome
6. "David" modeled in bronze in 1476 by Andrea del Verrocchio (1435–88), Italian realist
7. "Meeting of Saints Francis and Dominic," an enamelled terra cotta lunette by Andrea della Robbia, nephew and pupil of Luca della Robbia, the first artist in Italy to apply the art of glazing terra cotta to monumental sculpture. Executed between 1490 and 1495 in the loggia of the Hospital of S. Paolo, Florence
8. "Apollo," one of four statues by Jacobo Sansovino (1486–1570) surmounting the arches of the Loggetta dei Cavalieri, Venice
9. "Diana and the Stag," a fountain designed by Jean Goujon (*c.* 1520–*c.* 1566) for the château d'Anet. Now in the Louvre

RENAISSANCE AND MODERN SCULPTURE IN EUROPE AND AMERICA

1. "Rape of the Sabines" by Giambologna (1529–1608), Italian. In the Loggia dei Lanzi, Florence. 2. "Milo" by Pierre Puget (1622–94), French. In the Louvre. 3. "Mercury" (putting on his sandals) by Jean Baptiste Pigalle (1714–85), French. In the Louvre. 4. "Clytie" by William Henry Rinehart (1825–74), American. 5. "Night with her children Sleep and Death," a bas-relief in marble by Bertel Thorwaldsen (1770–1844), Danish. 6. "California" by Hiram Powers (1805–73), American. 7. "Perseus with the head of Medusa" by Antonio Canova (1757–1822), Italian. In the Vatican. 8. "Nymph and Satyr" by Clodion (1736–1814), French. 9. "Jeanne d'Arc" by François Rude (1784–1855), French. In the Louvre

of the *Medici Tombs,* Florence, and in the *Seated Moses,* which was to have been a part of a colossal mausoleum for Julius II. His *David,* Florence, is sensationally realistic and his *Pietà,* in St. Peter's, Rome, anticipates in its superb pictorialism, its amazing and dramatic technique, and its tender sentiment the greatest characteristics of the baroque sculpture of the following century.

Among the later renaissance sculptors Jacobo Sansovino (1486–1570) is notable for the technical excellence and classic grace of his figure sculpture in the Loggetta of Venice; Benvenuto Cellini (1500–1571) for his excellent decorative work and especially for the *Perseus,* in the Loggia dei Lanzi, Florence; and Giovanni Bologna (1524–1608) for his colossal fountains and the amazing dexterity which he often shows in the presentment of the human figure.

Outside of Italy, the Renaissance was most at home in France. Not only the subject-matter of classic sculpture, but also that Hellenic feeling for grace which informs also the best work of the Italian school, became thoroughly a part of the French tradition. In France the Renaissance is not, as in England, an alien mode. Jean Goujon (1510?–1566?) was a master of draperies and of the decorative rendering of the feminine form, not surpassed in the world. In his *decorations* for Pierre Lescot, Louvre, Paris, he has combined the most exquisite sensuous loveliness with classic restraint and dignity. Germain Pilon (1535–1590) though more realistic than Goujon attains at times a greater monumentality.

In Germany, where the religious wars prevented the extensive growth of sculpture, the new spirit met with more resistance. Renaissance ideas are fused with the Gothic in the decorative work of Peter Vischer of Nuremberg (1460–1529) and of his son Peter Vischer the Younger (1487–1528). England employed a few Italian artists; the Tomb of Henry VII. in the Chapel of Henry VII., Westminster Abbey, by Pietro Torrigiano (1472–1528), is one of numerous examples which were to prove a mine of ornamental motives to later decorators. Spain developed a more vigorous Renaissance tradition, sending her artists to Italy to study under the greatest masters. Of these Bartolomé Ordónez and Alonso Berruguete, both pupils of Michelangelo, are the most celebrated.

THE BAROQUE

A return to naturalism and to a dramatic pictorialism are the characteristics of the Baroque art that, after the 16th century, supplanted the classicism of the High Renaissance. The proportions which the classic canon had established for the human body retain their authority in the Baroque, but the calm and generalized features, the rigid, statue-like poses, give way to a physiognomy that is individualized and emotionally expressive, to attitudes that embody dramatic and often passionate movement. The draperies that clothe these classic forms no longer hang in graceful quiet lines, but, with deep and voluptuous folds, with broken profiles and abrupt shadows, they share, in a tumultuous movement, the agitation of the bodies they cover. These human forms are arranged in pictorial groups which enact some drama of ecstasy or cruel suffering among the modelled forms of trees and rocks, of architecture and curtained canopy, of floating billowy clouds and golden rays of sculptured light. Movement, not repose, and emotion, fervid and unrestrained, like that of the *Laocoön,* are the ideals of this somewhat theatrical art in which light and shade and colour, rather than form and proportion, are the principal actors.

Michelangelo was the first Renaissance sculptor to inform the classic types with superhuman energy and emotional intensity, and in the later work of Giovanni Bologna—such as the *Rape of the Sabine Woman* in the Loggia dei Lanzi, Florence—we find that delight in the contortion of form, and that astonishing virtuosity of modelling, which are to be among the striking characteristics of Baroque sculpture. But the great figure of the Baroque was Giovanni Lorenzo Bernini (1598–1680). A technician unexcelled in the history of sculpture, with an imaginative power second only to that of Donatello and Michelangelo, he, almost single-handed, created that grandiose and dramatic form which sculpture was to retain almost to the time of Napoleon. He is at his best in his great altars and magnificent tombs, but not less characteristic are his portrait busts—such as the *Louis XIV.,* at Versailles—in which an accurate and sympathetic characterization of features is combined with a theatrical opulence of costume and periwig. His youthful *Apollo and Daphne,* in the Villa Borghese, Rome, shows his power as an illustrator; the *David,* also in the Villa Borghese, is an example of his ability to infuse his figures with an intense and concentrated energy; and his *Ecstasy of St. Theresa,* in S. Maria della Vittoria, Rome, is among the most poignant picturizations of that "passionate mysticism" which characterized the Catholicism of his day.

Algardi, Cavallini, Borromini and Andrea Pozzo are among the successful Baroque sculptors who followed Bernini in Italy, finding in the facility of stucco a congenial medium for the exploitation of his style. But the political and economic weakness of Italy in the 18th century greatly limited the opportunities of her artists, and it is chiefly in the courts of Versailles and of Vienna that Baroque art, so consonant to the imperial spirit and to that of the Catholic reaction, received its greatest patronage. The Italian excesses in pictorialism and in emotional expression were tempered in France by the persistence of the classic tradition, while in Germany, where the late Gothic opulence of natural form had never felt the frigid touch of classicism, and in Vienna, where the Turkish invader had brought the fantasy of the Orient to the gates of Vienna, the baroque assumed a gaiety and exuberance beyond that of its native Italy. In Spain, a profound and active piety endowed many baroque sculptures with an intensity of devotional feeling which, although realistically rendered, recalls the ecstatic paintings of El Greco.

Guillaume Coustou I. (1677–1746) is a characteristic exponent of the Baroque in France. His *Louis XIV. Crossing the Rhine,* at Versailles (begun by his brother Nicholas Coustou) bestows on the Italian love of picture and allegory a graciousness that is wholly French. Pierre Puget (1620–1694), a pupil of Bernini, renders the effort of muscles and the whirl of draperies with a technical skill nearly equal to his master; his *Milo of Croton* in the Louvre is characteristic. Jean Baptiste Pigalle (1714–1785), in his *Mercury* in the Kaiser Friedrich Museum, Berlin, and in other works, illustrates that politeness of theme and that grace of treatment with which France endows the Baroque. Claude Michel, called Clodion (1738–1814), carries these tendencies to an extreme, combining them with a natural and sensual technique of rendering; his *Nymph and Satyr* in the Metropolitan Museum, New York, displays to great advantage the animation and charm of his best work. Jean Antoine Houdon (1741–1828) presages in his *Diana,* in the Hermitage at Leningrad, the return to the classic which is to mark the end of the 18th century. His portraits—of which the *Washington,* in the Capitol at Richmond and the *Voltaire* in the Comédie Français, Paris, are good examples—are unexcelled in their noble and sympathetic realism.

Andreas Schlüter (1664–1714), in his numerous tombs and in the *Expiring Warriors* of the Arsenal of Berlin, displays the vigorous and realistic Baroque of Germany, and Johann Bernhard Fischer von Erlach (1656–1723), in his *Trinity Column* in the Grabenstrasse, Vienna, illustrates its exuberance and joyousness. George Raphael Donner (1693–1741), the greatest Germanic sculptor of the 18th century, anticipates in his *Fountain of the New Market,* Vienna, the reaction towards classicism that brings the century to a close.

In England, the *Tomb of the Elder Pitt,* Westminster Abbey, by John Bacon (1740–1799); in Holland the opulent *Pulpit* in Brussels Cathedral, by Hendrik Verbruggen (1655–1724); and in Spain the *Virgin of the Immaculate Conception* by Juan Martinez Montañes (1570–1649) are characteristic examples of the national Baroque schools.

THE 19TH CENTURY

About the end of the 18th century an antiquarian enthusiasm, common to all European countries, created a reaction towards the classic in architecture, painting and sculpture. A widespread interest in aesthetic theory—a phase of that social and intellectual

ferment that preceded the Revolution—prompted the wide acceptance of an aesthetic system in which the ancient masterpieces, revealed anew by the discoveries and writings of archaeologists, are held up as the perfect models for modern imitation. When, at the beginning of the 19th century, the triumph of Napoleon, putting an end to the monarchial order which had sustained the Baroque tradition, gave the arts a patronage whose taste had been formed, not in court or in church, but in the pages of theorists and the galleries of museums, literary and academic influences became dominant in art. The static and generalized Greek statues, as revealed in a world of Latin copies, once more appear in the arts of painting and sculpture: life and movement, picture and emotion, portraiture and costume disappear before the Roman conqueror whose austere taste tolerates neither sentiment or story, neither religion or nature.

The new art, to which the name Neo-Classicism is given, differs from that of the Renaissance in its more complete and intransigent imitation of classic statues. The Renaissance artists, excepting a few of the minor masters of the 16th century, never created statues which directly reproduce in subject, pose, proportion, and surface treatment the models of antiquity. To them the antique was an inexhaustible source of inspiration, a mine of technical precedents, not a mould into which their own free and individual life was to be compressed. The antique was a language in whose musical cadences they expressed their own thoughts. To the Neo-Classic artist the antique was a system, a discipline, an inflexible and impersonal canon imposed upon him by authority.

Antonio Canova (1757–1822), an Italian, was the great master of the Neo-Classic. His *Perseus*, in the Vatican, reproduces directly the Apollo Belvedere; his *Venus Italica*, in the Pitti Gallery, Florence, is the Venus di Medicis of the Uffizi. In his portraits—such as the *Pauline Buonaparte* of the Villa Borghese, Rome—he gives to his contemporaries the simplified forms, the tranquil poses, the generalized features of Roman statues, and stripping them of their clothing, he gives to their bodies the sensuous charm of Praxitelian muscles. But he does not always escape the Baroque influence as his famous *Cupid and Psyche*, in the Louvre, shows; and there are many of his works, such as the *Hebe*, in the National Gallery of Berlin, in which nature and an almost Gallic feeling for elegance and warmth put to rout his academic principles. He was a greater man than his theories; to his fine taste and generous character, no less than to the temper of his time, he owed his immense popularity.

Bertel Thorwaldsen (1770–1844), a Dane who lived in Rome, whose coldly archaeological work had a tremendous vogue throughout the 19th century; Johann Heinrich Danneker (1758–1841), born in Stuttgart, who sometimes softened his correct style with touches of Baroque tenderness; and Johann Gottfried Schadow (1764–1850), who returns more than once to nature for inspiration, are the important figures among the Neo-Classicists. The *Adonis*, by Thorwaldsen, in the Glyptothek in Munich; the *Ariadne*, by Danneker, in Frankfort; and the *Princesses Louise and Friederike*, by Schadow, in the Royal Palace of Berlin, are examples of their work. The Neo-Classic is represented in England by such sculptures as the *Earl of Mansfield Monument*, by John Flaxman, in Westminster Abbey, and in America by the *California* of Hiram Powers (1805–1873) in the Metropolitan Museum, and by the *Clytie* of William H. Rinehart (1825–1874) in the Peabody Institute, Baltimore.

The history of sculpture after the first quarter of the 19th century is a record of the effort of sculptors to escape the arid tyranny of Neo-Classicism. The romantic spirit, which took possession of literature, painting, and architecture, did not prevail in sculpture until, near the end of the century, Rodin led a final and successful assault against the academic entrenchments. The definite inherited subject-matter of sculpture proved less tractable to the excessive individualism, itself a facet of romanticism, which invaded the other arts. In the meantime, sculptors tried, not without success, to widen the range of classic sculpture by endowing it with movement, subjectivity, decorative charm, costume, and, at times, with truth. The era is one of experiment and research; we are no doubt too near to it to appraise it judiciously or to interpret adequately its deeper significance.

François Rude (1784–1855), in his thrilling *Marseillaise*, on the Arc de Triomphe, Paris, illustrates the way in which romance sometimes took possession of the classic figures, compelling them to attitudes of passionate movement. His *Neapolitan Fisher Boy* in the Louvre, a *genre* subject, and his *Marshal Ney*, who waves his drawn sword above the flowers of the Place de l'Observatoire, Paris, are other examples in which classic beauty, clothed in modern costume, assumes a modern posture. David d'Angers (1788–1856), whose skill and mastery of classic form is well exemplified by the fine *Philopoemen*, in the Louvre, brought "local color" into classic art in his costumed figures of his contemporaries. Antoine Louis Barye (1796–1875), the most original and virile sculptor of his time, escaped altogether the classic forms by devoting himself to animal sculpture, giving to the forms of tigers, elephants and bears an intensity of life and a conciseness and breadth that recalls Egyptian examples. Jean Baptiste Carpeaux (1827–1875) attempted to develop the Neo-Classic in the direction of the Baroque; he re-established in his *Dance*, on the façade of the Opera House, Paris, a sensitive, gracious and rhythmic pictorialism that resembles the work of Clodion.

In Germany, Daniel Christian Rauch (1777–1857), a pupil of Schadow, carried on, with touches of naturalism, the Neo-Classic tradition; his *Joseph Maximilien*, in Vienna, is a characteristic work. Reinhold Begas (1831–1911), a master of the feminine nude, found, like Carpeaux, inspiration in the Baroque; and the Baroque, in its lighter and joyous mood, was also exquisitely interpreted by Viktor Tilgner (1844–1896), whose *Monument to Mozart*, Vienna, has caught delightfully the spirit of the master that it commemorates. Adolf Hildebrandt (1847–), who is one of the great masters of our time, returns to the classic nude, freeing it both from movement and from subjectivity. In his *Masculine Nude*, in the National Gallery of Berlin, he has recaptured admirably the simplicity and repose of the Greeks without enslaving himself to their conventions.

In Italy Neo-Classicism had but a feeble life after Canova, giving way after a brief period to that literal and sugary style from which Italy has been only recently redeemed by the impressionism of Medardo Rosso and his school. In England, Alfred Stevens (1817–1875) escaped almost altogether the Neo-Classic influence; his *Caryatides* are the work of a virile and original artist whose genius, unhappily, found but few opportunities for its expression. Hamo Thornycroft (1850–) ennobles his classic nudes with lovely and natural sentiment.

In the United States, John Quincy Adams Ward (1830–1910) was the first important sculptor to temper the classic tradition with some effort towards national feeling. His style is dry and sometimes uninspired, but always robust and unaffected. Augustus Saint-Gaudens (1848–1907) attained in his best work a charming equilibrium between poetic grace and an austere idealism. His *Monument to the Wife of Henry Adams*, in Washington and his *Lincoln*, in Lincoln Park, Chicago, nobly continue the classic tradition of France. Daniel Chester French (1850–) is a superb technician who endows American themes with nobility and power. His *Death Staying the Hand of the Sculptor*, in Forest Hills Cemetery, Boston, is one of the loveliest pictorial reliefs of our time.

CONTEMPORARY SCULPTURE

Auguste Rodin (1840–1917) was the first sculptor to challenge successfully the classic authority. Taking nature, not tradition, for his guide he created a purely naturalistic sculpture, almost wholly free from architectonic form. Not structure, nor abstract harmonies of mass, are emphasized in his work, but rather the natural loveliness of flesh, in the rendering of which he recalls Praxiteles and the Hellenistic masters. This realism he used as a medium for narrative and for the expression of sentiment. His sculptures are a series of pictures in which characterization and action, ideas and romance, not form, are the things insisted upon. To attain these, he eventually sacrificed even his realism, developing an impressionistic style which permits a distortion of nature

SCULPTURE OF THE 19TH AND 20TH CENTURIES

1. "Ugolino and his Sons" by Jean Baptiste Carpeaux (1827–75). Formerly in the Jardin des Tuileries, now in the Louvre
2. "The Kiss," a marble group by Auguste Rodin (1840–1917) representing Paolo Malatesta and Francesca da Rimini. First exhibited 1898
3. "The Hewer" by George Grey Barnard (1863–)
4. "Lion and Snake" by Antoine Louis Barye (1796–1875). Now in the Metropolitan Museum of Art
5. "Madonna of Alsace" by Emile Antoine Bourdelle (1861–)
6. "The Millmore Memorial," also known as "Death and the Sculptor," by Daniel Chester French (1850–)
7. Portrait of Mme. Warroquier by Charles Despiau (1874–)
8. "Baigneuse Acoudée" by Aristide Maillol (1861–)
9. Puritan Statue by Augustus St. Gaudens (1840–1907) representing Deacon Samuel Chapin, one of the founders of Springfield, Massachusetts

RENAISSANCE GARDEN SCULPTURE AT VERSAILLES AND FLORENCE

1. Fountain of the Pyramids executed in lead by François Girardon (1630–1715) from drawings by Claude Perrault (1613–88). In the Parterre du Nord, Gardens of Versailles
2. Springtime by Simon Mazière (1649– ?). In the Gardens of Versailles
3. The river Achelous by Simon Mazière. In the Gardens of Versailles
4. Ceres by J. B. Poultier (1653–1719), one of a row of marble statues near the entrance to the Lawn in the Gardens of Versailles
5. One of the 22 leaden vases forming part of the Fountain of Neptune, a great semi-circular fountain in the Gardens at Versailles, begun by André Le Notre (1613–1700), and Jules Hardouin Mansart (1645–1708), architects of the park, and completed in 1740
6. The River Dordogne by Charles Antoine Coysevox (1640–1720), cast in bronze by the Keller brothers (1635–1700 and 1638–1702), one of eight statues representing the principal rivers of France. In the Gardens of Versailles
7. Fountain by Alfredo Paragi in the Boboli Garden, Florence, a park laid out by Tribolo in 1550 for Cosimo I.
8. The Garonne river by Charles Antoine Coysevox, cast in bronze by the Keller brothers. In the Gardens of Versailles
9. The Lyric Poem, marble statue by Jean Baptiste Tubi (1635 or 1630–1700) (with C. A. Coysevox). In the Gardens of Versailles
10. Fountain of Venus by Giovanni Bologna (1524–1608) in the Royal villa of Petraja, Florence
11. The Heroic Poem, marble statue by Jean Drouilly (1641–98). In the Parterre du Nord of the Gardens of Versailles

and an elimination for the sake of emphasis far in excess of that permitted by the classic canon.

The Kiss, in the Musée Rodin, Paris, is a characteristic work, illustrating not only the natural proportions and treatment of the body which Rodin substituted for the classic canon, but also the sensuality and formlessness, the romantic and subjective quality, of Rodin's art. The *Victor Hugo* in the garden of the Palais Royal, the *Thinker,* in the front of the Pantheon, Paris, are also among his best works.

The influence of Rodin was paramount in the art of sculpture until after the period of the World War and remains perhaps the most important element in contemporary work. Everywhere it has sanctioned a popular realism, encouraged a subjective and individualistic development, and tended to destroy not only the authority of tradition but to prevent the growth of any new continuity in sculptural development.

Max Klinger (1857–1890) is an example of the extreme individualist in sculpture. A literary and even mystic interpretation is required by his pictorial and formless works, among which the *Beethoven* of the Leipzig Museum is perhaps the best known. Constantin Meunier (1831–1905), a Belgian sculptor, is more directly influenced by the pictorial romanticism of Millet; his realism, his admirable technique, his impressionism, are informed with democratic sentiment. Medardo Rosso (b. 1866) an Italian, and Paul Troubetskoi, a Russian (b. 1866), are among other important members of the pictorial and emotional school of Rodin. George Grey Barnard (b. 1863) belongs also to this school. An artist of great originality and force, he is like Rodin in his realism, in his love of symbolic and moral values in form, and in his impressionistic technique. He is, like Rodin, not untouched by Baroque tendencies. His *Great God Pan,* on the campus of Columbia University and his *Hewer* in the Brooklyn Art Institute, are among the fine achievements of American sculpture. Other American artists who deserve a more extended notice than is here possible are: Paul Bartlett (b. 1865), Gutzon Borglum (b. 1867), Charles Grafly (b. 1862), Paul Manship (b. 1885), James E. Fraser (b. 1876), Edward McCartan (b. 1878), Mahonri Young (b. 1877), Leo Lentelli (b. 1879), and Malvina Hoffman.

Before the death of Rodin a reaction against his art had commenced. The realistic and interpretive art of the great romanticist had ignored those architectonic qualities that had ennobled sculpture in its greatest periods. To recapture these qualities without again subjecting sculpture to the deadening influence of formulae —to free sculpture from symbol and picture and restore it as a form-giving art—has become, in our time, the aim of an increasing number of artists.

Among these, Aristide Maillol (b. 1861), Antoine Bourdelle (b. 1861), Joseph Bernard (b. 1870), and Charles Despiau (b. 1874), are most prominent. All were pupils of Rodin, and retain in their work much of Rodin's worship of nature and vigour of technique; but, unlike Rodin, they do not use natural forms as a medium for emotion or thought. Nature, rather, is the basis from which they build up a design of plastic and harmonious forms. Bourdelle has the greatest range of imagination and achieves in his best work a superb vitality combined with an impressive solidity and breadth of treatment: his *Herakles,* in the Luxembourg, is as charged with arrested energy as the bow he bends and yet is designed with the most studied care for balance of masses and for plastic rhythm. Maillol, who has had the greatest influence of any sculptor since Rodin, arranges figures of great natural loveliness into compositions that attain the serenity of Hellenic art: in his *Monument to Cézanne,* for example, which contrasts strangely with Bourdelle's *Herakles,* being wholly without strain or effort, nature and design reach an almost perfect equilibrium. Despiau excels in portraiture, producing busts that have an arranged and exquisite naturalism. Bernard, whose work embodies most directly the essential characteristics of modern art, is at his best in such decorative works as the *Femme et Enfant Dansant,* in the Luxembourg, in which forms derived from life are simplified and woven into a rhythmic pattern.

Frank Dobson, Gaudier-Brzeska, and Eric Gill are the most notable exponents of modern sculpture in England. Dobson's work, like Maillol's, is usually severely architectural and most satisfying in the formal values it achieves. Gaudier, who was killed in the World War, was a sensitive and original artist of the highest endowments. Gill is less brilliant, but a splendid technician. In Germany, George Kolbe's work exhibits a most interesting and promising synthesis of movement and formal harmonies; and in Spain, Mateo Hernandez (b. 1897) creates from the carefully-observed forms of animals, translated into diorite, living designs that attain a simple and elegant formalism. The Balkan sculptor, Ivan Mestrovic (b. 1883) is perhaps the most virile and original sculptor outside of France and is one of the few contemporary artists wholly free from French influence; his sculptures, full of racial rather than personal significance, have a feeling for materials and for architecture like that revealed in archaic Greek sculpture.

In recent years the reaction from Rodin's representational art has gone so far as to create a sculpture in which descriptive modelling is almost entirely eliminated. In order to attain an intense aesthetic expressiveness, the simplification of mass and the elimination of detail are carried so far that sculpture tends to become almost wholly an art of abstractions. Conceived forms and arrangements, which have always been the chief pre-occupation of sculptors, are held to be independent of observed forms and arrangements. That emotional energy that is inherent in sculptured masses is, it is thought, obscured and often defeated by symbolic or descriptive attributes or by an emphasis upon reproduced organic forms. Alexander Archipenko, Constantin Brancusi, Ernst Barlach, Moïse Kegan, Ossip Zadkine, Wilhelm Lehnbruck, Henri Laurens, Modigliani, Joseph Czaki, and John Mowbray-Clarke are among the many sculptors whose experiments in this new field have resulted in works of great interest and charm. Jacob Epstein (b. 1880), one of the most talented and vigorous sculptors of our day, has, apparently, abandoned his experiments in abstract design for a romantic and realistic art more akin to that of Rodin.

GARDEN SCULPTURE

Strictly speaking garden sculpture is not in a class by itself. Very often we may find in a garden a figure taken from the ruins of some old Gothic cathedral which makes a perfect piece of garden sculpture, or again we may see a fragment of a Greek statue or even an old Chinese idol which when given just the right setting seems to be a necessary part of the garden in which they are placed. Not all sculpture, however, is suitable for a garden decoration even though it be very fine sculpture from the point of view of composition or modelling or the expression of an idea or an emotion. Therefore, it would be well to consider here the things which make a piece of sculpture take its proper place in a garden or park.

One of the first requisites of a successful garden decoration is that it be something that will make a pleasing spot and be part

of the ensemble. It may be an old well-head or a great stone or terra-cotta vase which will serve the purpose best; it may be a great jet of water shooting straight up from a pool or simple basin; it may be a statue in stone, lead or bronze. Regardless of what it is, in order to take its proper place in a garden it must have just the right scale and colour.

This question of colour is a very important one. Quite often a fine statue in bronze placed against a background of thick dark foliage is completely lost and counts for nothing as a decoration, whereas a statue in stone on just the right scale, though it may be crudely executed, will be much more successful as a decoration because it counts as a spot of colour where the dark bronze was lost as a silhouette against the trees or shrubbery. Where bronze is used it should be shown silhouetted against the sky or against a garden wall or terrace where the dark bronze will be in contrast to the lighter background, for even though the bronze be light in colour when first placed out of doors it will soon lose its original patina, and gradually grow darker in colour. It is practically impossible to give to bronze an artificial patina which will not change colour when exposed to the elements. (*See* BRONZE: *Corrosion and Restoration.*) Marble or stone, on the other hand, when placed out of doors will most often take on a beautiful mellow tone which is in perfect harmony with the landscape and at the same time make a perfect silhouette against the green. (*See* STONE CARVING.)

When placed in the open, lead will also take on a very pleasing colour, a soft warm grey which always makes an agreeable spot. Lead is especially suited to fountain figures, and very often when seen in the moonlight it takes on a beautiful silvery tint, an effect which can be obtained by the use of no other material.

There are, of course, various forms of landscape gardening, each requiring a different treatment with regard to its sculptural decoration, but they divide themselves into two general classifications. First, there is the large formal garden or park with its long straight paths, its carefully planned vistas and beautifully kept lawns; then, there is the small informal garden with its nicely arranged flower-beds and its small intimate nooks. One thinks of the park in Versailles or of some of the beautiful old gardens of Italy which were designed as settings for the villas of aristocracy in the time of the Renaissance as fine examples of the large formal garden. At Versailles there is a profusion of sculpture all taking its proper place in the surrounding landscape and though the work was done by several different men there is no lack of harmony in design or execution and each figure is simply a part of a beautifully planned ensemble. Where they placed rows of statues against a heavy mass of foliage bordering some broad grassy avenue they always used stone; when they placed statues out in the open where they were silhouetted against the sky or against the water of some great pool they used bronze or lead, with the result that the sculpture always counts as a spot of colour and adds greatly to the beauty of the ensemble. One may feel that a piece of sculpture which is to be placed in the open should be rugged in treatment and massive in design. This may be true in regard to sculpture to be placed in a large open square or plaza of some big city, or of a monument or a group for some great building, but a single figure or group for a garden must have a certain refinement of detail and elegance of design such as nature has given to the flowers and trees, and all the things with which to make the garden a thing of beauty.

One may again feel that a piece of sculpture should be more or less of a solid mass free from holes which pierce the composition. This may be true of certain kinds of sculpture, but in garden sculpture where the single figure or group in stone is silhouetted against the dark green of the trees it is sometimes well to have carefully designed holes which will give to the group a certain lightness and freedom which is in keeping with the design of the trees where the branches sometimes part and allow a glimpse of the sky beyond.

While the small informal garden requires a different type of sculpture from that of the large formal garden the same principles of scale and colour should be applied here as in the larger gardens. If the setting calls for a statue, say, 3 ft. high, it does not necessarily mean that any statue 3 ft. high, however charming, will suit the place. A statuette which may look well indoors is clearly lost when placed outdoors because its mass and details are out of scale with the things of nature which surround it.

While the subject matter of garden sculpture is not perhaps of first importance one nevertheless feels that there are certain subjects more suited to the garden than others. One is inclined to think of the mythical woodland creatures and of subjects that are joyous and which have to do with life in the open. However, whether the statue be a small chubby child or a goddess done in a fine architectural style it must first of all be a thing which takes its place in the garden and is in harmony with the trees and flowers which are its neighbours.

Thus it is that many garden decorations though crudely executed make pleasing spots when seen from a distance and are therefore in a way successful, but the really successful garden decoration is the one which makes a good spot when seen from a distance and which at the same time is designed and executed in such a manner as will repay anyone who comes near enough to inspect it as a work of art. (*See* also LANDSCAPE ARCHITECTURE; SCULPTURE TECHNIQUE.) (E. McC.)

PORTRAIT SCULPTURE

Good portrait sculpture has remained essentially the same throughout the ages. Only its trappings and its ornamentation have undergone changes, just as conventions of dress have changed periodically, characterizing a particular epoch. Thus we may recognize an Egyptian portrait bust by the indication of its wearing apparel or its mode of arranging the hair, while excessive attention to personal adornment indulged in the late 18th and in the 19th centuries leaves its stamp also upon the portraiture of that period.

In essentials, however,—in the fundamental construction of the human head,—the fine portraiture of these remotely associated periods remains the same. You see on the city streets to-day types that coincide exactly, except for the non-essentials of dress, with the types richly revealed in the best portraiture of the Egyptians and of the Romans. This fact leads back to the very foundations of portrait sculpture and of human construction. Everyone knows, for example, that the nose is in the centre of the face and that, accepted as the centre, it can give the alignment of the other features. Yet many portrait busts neglect this simple first principle, and, in consequence, destroy the normal perfect balance of the head.

GEOMETRIC BASIS

The fundamental law of head construction is, in consequence, as much a truism as a law in geometry and must be accepted without reservation by the portraitist. If it were actually reduced to mathematical principles it could be indicated by a line drawn down through the centre of the head from the apex of the skull to a point marking the centre of the mass attaching the neck to the body. This imaginary line might be described as the "flow" of the mass (*A–B*, fig. 1).

In order to complete the geometry of portrait bust construction a straight line may be drawn at right angles to the general line of the "flow" running from the eye to the back of the skull and centring eyes and nose (*D–C*, fig. 1).

Structure and Likeness.—Once this framework of fundamental construction has been produced the matter of obtaining a likeness is comparatively simple, and the features with their individualizing characteristics are at once seen to be ornaments on the general flow of the head construction just as buttons or embroidery are ornaments on the coat or dress.

The sculptor who has spent years studying the human head knows well that good portraiture is concerned with the individuality of the simple head construction as indicated by the "flow" of the mass rather than by the meticulous copying of the features. He knows from studying the work of his fellows that there are two types of portrait sculpture, one type preoccupied with features, and the other with the fundamentals of construction. There is a unity in the bone structure which he perceives is not built brick

EXAMPLES OF GARDEN SCULPTURE

1. Torso by Elie Nadelman, on the estate of Ralph Pulitzer at Manhasset, Long Island
2. "Diana" by Edward McCartan, in the garden of the H. W. Crofts' estate in Greenwich, Connecticut
3. A marble figure by John Gregory, in an inner court of the home of S. R. Guggenheim, Pt. Washington, Long Island. The base is decorated with acanthus leaves
4. "Woman With a Child" by Paul Manship, on the estate of C. M. Schwab at Loretto, Pennsylvania
5. "Sonata" by Mario Korbel, in the garden of George G. Booth at Detroit, Michigan
6. A fountain by Paul Manship

on brick as is a man-made work of architecture and which if grasped in its entirety lends a semblance of life; a quality of convincing sureness which cannot otherwise be obtained.

It is quite possible to achieve a likeness without adhering to fundamentals, but as the years pass and the subject dies the portrait bust must rest on its merits as a work of art and not as a likeness. The Romans who posed for some of the finest examples of ancient portraiture have long since passed from the land of the living. No one living to-day has an interest, sentimental or otherwise, in the tilt of the ancient's nose or the dear and familiar lifting of the ancient's eyebrow. The personal element in portraiture is stripped from consideration by the impersonal passage of time, and the work is left to stand or fall on its value as a piece of head construction. It is not at all improbable that some of the ancient portraits preserved to-day as the finest relics of antiquity in the museums of the world won less acclaim in their own era than other works more effective as likenesses than as art.

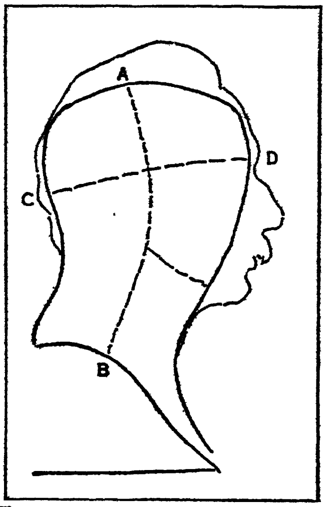

FIG. 1.—DIAGRAM SHOWING FROM A TO B THE PLANE OF THE STRUCTURAL MASS OF THE HEAD; FROM D TO C A SECOND LINE PASSING AT RIGHT ANGLES, CENTRING EYES AND NOSE WITH BACK OF SKULL

GOOD PORTRAITURE UNIVERSAL, NOT RACIAL

Granting the fundamental principle upon which the human head is built it follows naturally that good portraiture is universal and not racial. Because a portrait is primitive African or Egyptian or Chinese does not mean that it is any better as a portrait than a bust produced in Rome, Paris or New York. Racial differences occur from the frontal bone to the chin (Pl. I., figs. 3 and 8) and do not affect the real mass structure of the head.

By the same reasoning it would be a thankless task to establish the superiority of any one period of portrait sculpture over another. The factor of time is unimportant. A portrait that was good in the days before Christ is good to-day and takes its place with the best portraiture produced by the succeeding ages down to the present time.

The fundamental construction of a head, while of paramount importance in its valuation, is less striking to the layman than external characteristics. It is difficult, for example, to appreciate the structural kinship between a highly conventionalized portrait bust of an Egyptian king and a work emphasizing the individuality of a less exalted personage. Yet the difference between the highly individualized and the highly conventionalized portrait may lie solely in the treatment of externals.

Externals Establish the Period.—It is the outer convention rather than the inner structure that brands a portrait bust as the work of some particular period. The mode of life, the customs and manners and environment of the age invariably affect the outer appearance of the individual. Sometimes the mode of dress or the coiffure establishes what might be considered a symbol of the time, and this symbol or convention finds echo in the work of the portrait sculptor (Pl. I., figs. 1 and 7).

A study of Cambodian heads (Pl. I., fig. 7) or those produced in Egypt (Pl. I., fig. 2) and in Rome (Pl. I., fig. 4) shows the influence of the current mode on the work of art. The Cambodian portraitist in particular followed a definite symbolism in the rendering of the hair, while the popular coif of other lands is repeated with more or less conventional emphasis in the fashioning of the portrait bust.

Thus, although the individual was an individual in ancient lands quite as much as in the Europe and America of to-day, certain characteristics of dress stamp him with the life of a definite period.

Conventionalization and Realism in Portraiture.—It is interesting to note that many periods of art production showed equal interest in conventionalization and in realism. The modern tendency to reduce all forms to their simplest essentials is no new thing. It merely serves to emphasize and accept the principle of fundamental construction, and to publish to the world that details are merely details and have very little to do with the basic character of a work of art. Conventionalization of human forms (Pl. X., fig. 3) and simplification with the resultant absence of personal characterizing details (Pl. I., fig. 5) may be found in portrait sculpture from earliest times to the present era.

In Egypt, as well as in China, India and Cambodia, the conventionalization of forms was particularly favoured. Many of the fine renderings of kings and queens (Pl. I., fig. 1) are so highly conventionalized that the personal characteristics are lost or obscured. If one may judge by the mass of portraiture that has come down to us the high dignitaries of the religious and governmental life were placed on a plane above human characterization and were considered more as symbols of the church and State than as individuals. Yet, paralleling the conventional in portraiture there was a wealth of individual representations indulged usually in subjects of lesser rank, but presenting a definite individual character with all the eccentricities, all the imperfections of the ordinary man (Pl. I., figs. 2, 3 and 9).

Realism in the development of the portrait bust began almost with the first known portrait and marched triumphantly through the centuries, cropping out in unexpected places even in the great cathedrals of the middle ages where, carved on choir stools or as incidental architectural decoration, there are hundreds of little portrait busts characterizing the artisan or the ecclesiast or even the aristocrat of the time. Occurring as they did in an epoch devoted not to portrait sculpture but to architecture they serve to demonstrate the tremendous urge of the human race toward the perpetuation of the individual.

There is a slight shade of difference in viewpoint between conventionalizing and idealizing the human head. In conventionalizing the sculptor chooses the characteristics of subject and period and reduces them to decorative forms and symbols. Thus we find the hair of the African or the coiffure of the Cambodian expressed not realistically but by means of conventionalized decoration (Pl. I., figs. 7 and 8).

It remained for Rome, however, to lay final stress upon the individual as an individual. The long succession of portraits that issued from that city in the centuries of its world dominion show clearly the swing of the art pendulum from idealization and conventionalization to the frank acceptance of human imperfections. Sculptors delighted in these imperfections, these marks of personality, and expressed them with a realistic force that is as powerful to-day as it was in the long ago. Realism so held the portraitist in its grip that he often forgot the dress of a man and centred his attention upon the fundamental characterization of his subject as a timeless individual. The finest of these heads are, in consequence, forever modern as they reveal the human being stripped of period identification (Pl. I., fig. 4).

The Decline of Portrait Sculpture.—For many years after the Roman era portrait sculpture declined with the other arts, appearing only incidentally through the middle ages, and not returning to prominence much before the 18th century when, as in the past, it mirrored in its externals the modes of the elaborate elegance, following through almost two centuries an over-ornate career, yet, under its outer trappings, producing some fine examples of sculptural portraiture.

The 20th century is witnessing a return to the general simplicity found in the portraiture of the ancients.

DIFFERENCES IN VIEWPOINT AND MODELLING

A study of portrait heads produced throughout the ages reveals a rich variety of viewpoints and of modelling. Everyone is familiar with the unanimated face. You see it sitting opposite you in the public conveyance. Its expression has settled to that of hopeless, inactive monotony. For purposes of characterization it might be termed a "street-car face." This aspect of portraiture may have

a variety of underlying causes. The sculptor may be frankly bored with the subject. He may lack understanding of the subject and be unwilling to exert himself sufficiently to establish mutual sympathy. He may be faced with a personality that refuses to give that sympathy. Or, through lack of experience and inability to handle his medium, he may neglect the life-giving structural essentials.

In his effort to achieve simplicity a sculptor often gives the big essentials of head construction but so covers them with a general modelling that the richness of surface is lost. This type of portraiture reminds one of a figure neatly enveloped in a veil, or generalized by the use of tights. It is the antithesis of rich form sculpture in which detail is held in perfect scale to and is supported by the mass (Pl. XII., fig. 2).

At the other pole is the portrait head that achieves likeness and individuality by thinness of form, as if the artist were working with a drawn line upon the clay, emphasizing detail rather than construction, a type of work implying a pen and ink mental approach and readily defined as "pen and ink sculpture" (Pl. I., fig. 6).

The exaggeration of individual characteristics with extreme emphasis upon striking details supplies another classification under the head of caricature (*q.v.*).

PRODUCING A LIVING PORTRAIT

To produce a portrait bust that gives the impression of life the sculptor must have behind him a wealth of experience. He must know that a man does not laugh with his mouth or his eyes alone but with his entire head, and that when he smiles there is a concerted movement of all the features (Pl. XII., fig. 1).

Every subject has a definite life flavour that reveals itself in some individual characteristic or series of characteristics. The successful portrait head discovers these characteristics. Needless to say, the sculptor who has personal knowledge of his subject can produce a more living bust. But he is seldom called upon to execute a portrait of an intimate friend. The portrait commission concerns itself almost exclusively with the perfect stranger, and when faced with such a sitter the sculptor must draw largely upon his knowledge of human nature and his ability to read facial characteristics in the light of the subject's environment and profession. What he does and is contributes largely to the basis for character analysis.

When the sculptor gropes unsuccessfully for this revelatory contact he produces the unanimated street-car face, visualizing the man on the model stand as impersonally and monotonously as he would the man beside him in a tram. The features are there; the likeness may be there also, but the personality, the life-giving quality of understanding between subject and artist, is absent.

Sculptor and Sitter.—In many respects a portrait head created from memory may have more life than one executed after many sittings. Sitters vary greatly in what they give of themselves. Some are sympathetic and establish at once a bond of sympathy with the sculptor, thus enhancing his creative power. Others sit through hours without a spark of understanding. It is often true that more can be gained by talking to a subject during rest periods and by studying the reaction of the man when he is unconscious of a pose than when he sits through the long hours on the stand. After a time the expression of any face sets, and there is danger of reproducing a deadened countenance.

One of the most difficult tasks that a portrait sculptor is called upon to face is the commission to make the head of someone no longer living. Many busts of historical personages are created solely from contemporary prints, photographs or portraits, the character of the data varying according to the period in which the individual lived. Seldom is there adequate material from which to work. If the portrait desired is that of some notable who lived many years ago the artist may wield a freer hand and use his own knowledge of the human head and his conception of the man's character without being forced to meet the criticisms and suggestions of relatives or friends whose impressions of the individual may be vivid but conflicting (Pl. X., fig. 1). The one hope of success lies in the sculptor's knowledge of construction and in the wealth of his experience as a portraitist, and with this knowledge and experience he must portray that intangible quality known as character. It is no task for the novice.

Studying Colour in Portraiture.—The experienced portraitist understands many subtleties of construction that are missed altogether by the literal copyist. He appreciates, for example, the structural differences between the blonde and the brunette. He knows that dark hair and light hair fall in different masses and that even when dark hair whitens with age it still preserves the mass quality of its original colour (Pl. XII., fig. 3). Thus hair of different colours is essentially different in form.

Black hair falls in heavier masses and gives a solid effect. Where it separates and one lock appears distinct from another the separation is sharp and produces a strong shadow. Blonde hair, on the other hand, has very few solid masses. It is fluffy and light in effect and does not possess either the solidity or the sheen of dark hair (Pl. XI., fig. 4). The difference between blonde and brunette indicates at once the need for a corresponding difference in the modelling of each type. Forms that are definite and that produce definite shadows give a brunette colouring while blonde colouring is obtained through a negation of the shadows and by the modelling of subtle, less well defined forms.

How Colour Impression Is Produced.—The portrait bust of the past few centuries has relied for colour quality almost entirely upon gradation of shadow produced by modelled form. Dark skin, light skin; dark eyes, light eyes; dark hair, light hair,—such colour differences are translated in terms of light and shade.

This sculptural interpretation of pigments was aided by the ancients through actual colour application as seen in many a portrait discovered on Egyptian soil (Pl. I., fig. 2). Chinese portrait heads were also coloured, while a similar tradition reappeared in the ecclesiastical heads of the middle ages. It was possible for the Egyptian portraitist to paint on the bust the elaborate necklaces and jewel arrangements that give a clue to the mode of dress and of life. Crowns and head-dresses, first expressed in terms of form, were then painted in designs and colours characteristic of the period (Pl. I., fig. 1).

When the actual application of colour fell into disuse it became necessary for the portraitist to indicate pigments and design solely through the modelling of form. Folds of the toga might appear in Roman portraiture, while the coiffure of the lady of antiquity, changing with the style of each succeeding era, writes its chapter in the conventions of the portrait head.

The Influence of Externals on Portraiture.—The elaborate over-decoration of the 18th century and the heavier decorative trend of the 19th found echo in the accessories of dress used by the portrait sculptor in his effort to establish the individual in point of time as well as in point of character (Pl. X., fig. 1).

Externals thus leave their stamp upon the portrait bust as it marches through the ages, but externals have never made the portrait a finer work of art. It stands or falls by virtue of its construction, its modelling and the artist's own knowledge of human nature.

THE CHOICE OF MATERIAL

The modelling of a portrait head and the choice of size, whether life-size or over, is largely conditioned by choice of the material in which the head is to be cut or cast.

Wood, stone, metal and terra cotta provide a range of choice for the portrait sculptor, and each of these materials has its own technique. In Egypt stone was a favourite material, and the great simplicity of many an Egyptian portrait head may be due to the fact that the sculptor chose porphyry as his material for expression. Porphyry presents its own problems in the matter of carving. It is very hard, and necessitates the simplifying of surface treatment and the reduction of forms to their basic essentials. In Greece and Rome, on the other hand, where marble was so largely used, the sculptor had more opportunity to display his skill in the handling of intricate surfaces with greater attention to detail.

The control of the material over the modelling and even over the general conception of the work undertaken may be readily understood if a porphyry head of the Egyptians, with its simple

REALISM AND CONVENTIONALIZATION IN RECENT PORTRAITURE

1. Portrait of Lafayette by Jean Antoine Houdon (1741–1828)
2. Portrait of Admiral Farragut by Charles Grafly (1862–1929)
3. Portrait of Madam Pogany by Constantin Brancusi (1876–   )

forms, is placed side by side with a Gothic group of the middle ages, carved from Caen stone or from some other soft stone material. No such flowering of detail and intricate design in sculpture would have been possible had the carvers of the middle ages and the Renaissance been confined to the use of a hard, unyielding stone.

The hard stone thus lends itself to conventionalization, urging the sculptor on to express form more or less symbolically, while the soft stone allows him to indulge his fancy for absolute realism and for intricate ornamentation.

The Effect of Material on Size.—The sculptor who wishes his portrait bust to assume life-size proportions must, again, understand the material in which the head is to appear. If the portrait is to be cast in bronze it must be modelled slightly larger than life. Bronze shrinks $\frac{3}{16}$ in. equally in length, breadth and thickness, to the foot, and the heavier the bronze employed the greater the shrinkage.

Terra cotta, or dried clay, shrinks 1 in. to the foot, and does not shrink equally unless the model is so constructed that the shrinkage shall be equal. When the sculptor does not understand the terra cotta material the parts shrink unequally and the original model is either distorted, cracked, or both. Distortion of terra cotta pieces that have come down to us from antiquity may often be attributed to this cause.

In dealing with the portrait head carved in wood the sculptor must appreciate that a solid block of wood checks or cracks. Many African and Chinese portrait carvings show serious cracks. This tendency, however, can be controlled if the wood is built up by dove-tailing or glueing together smaller blocks to produce the required volume, or by boring and excavating the interior of the large solid block.

The Material May Aid Characterization.—It is not impossible that, in studying the character of the individual the sculptor discovers forms or traits that may be best expressed in some one particular material, thus utilizing the material as a direct agent in the characterization.

The artist who feels for his material understands that it requires a technique in keeping with its nature, and does not attempt to force upon it some alien treatment. For example, the beauty of wood lies in the fact that it is wood, and the sculptor who uses it as a carving basis should treat it as wood and not give it a surface peculiar to the nature of marble. If, on the other hand, he desires for characterization the surface of wood as a base, he should not choose marble.

PORTRAYING STATURE IN THE PORTRAIT HEAD

The portrait sculptor must indicate in the head alone the characteristics of his sitter. He is, therefore, faced with another interesting and difficult problem. How can he impart through the head the movement and form of the body? How can size, weight and stature be indicated in the bust?

Incidental decoration can do little to achieve this goal. The stature of an individual is a very basic thing and conditions all parts of the body from the head to the feet. In fashioning a portrait statue it is a simple matter to indicate size and weight. In the portrait head, however, such characteristics can be suggested in the setting or base. A portrait head, for example, must end somewhere and when ended must be mounted upon a block or base.

The Treatment of the Base.—The sculptor who studies the stature of his subject completes his portrait bust with a general form indicating the bulk of the sitter. If he happens to be a tall, thin person, the artist creates a tall, thin base (Pl. XII., fig. 1). If he be a short, heavy-set man, the base is wide and broad (Pl. XII., fig. 3). Any such setting goes back to a fundamental appreciation for form sensed by the ancients, and almost entirely forgotten in the over-ornate art of the 18th and 19th centuries.

GOOD PORTRAITURE TIMELESS

To-day, therefore, the sculptor stands as he stood thousands of years ago, face to face with the same problems of natural form that conditioned the portraiture of Egypt and of Rome. He has passed through centuries of experimentation during which his art became incrusted with extraneous and often meaningless details. Busts of this nature belong so exclusively to a certain period in the world's development that they give the impression of being out of date. They provide a gauge for the study of their own contemporary modes of dress, and because they are so localized they appear less modern than portraits executed thousands of years before by the sculptors of antiquity.

Many a fine portrait head created in Egypt or in Rome and produced purely as a study in structural forms and resulting life is ageless and periodless in its adherence to the universal principles of the sculptor's art. Conventions of dress, conventions of execution have come and gone, but the art of the portrait bust, in its fundamental aspect, has changed not one whit from the first efforts of a master hand to reproduce its kind.

MONUMENTAL SCULPTURE

By monumental sculpture is meant that sculpture which is intended to perpetuate the memory of a person or an event. Included in this definition are all types of memorials in which sculpture is the important part, even though architecture or mosaic or some other art may play an important part in the composition; but it is not intended to include that sculpture which forms merely a decorative accessory in a building such as the sculptures in temple pediments, in the portals of a cathedral, or on the piers of a triumphal arch even though these adorn a memorial structure. Sculpture of that type will be defined as architectural sculpture or as decorative sculpture. (*See* other sections of this article.) In the definition of monumental sculpture we include all public memorials that are sculptural in quality and intended to commemorate historic, literary or scientific events such as military victories, the signing of treaties, the discovery of new lands, or a mechanical invention; all memorials to persons—to statesmen, soldiers, poets, martyrs; all sculptural monuments intended to decorate a city; and all funerary sculptures, whether built within the walls of a cathedral or in the open air.

Monumental sculpture, to serve its purpose as memorial, must be permanent, and must clearly express the character of the person or event that it is meant to honour. Enduring materials, such as bronze or granite, so arranged as to be in perfect equilibrium and so modelled as to minimize the possibility of fractures would seem to be essential to this art; and it would seem obvious that these modelled forms should be those of men and women and should recall, either by direct representation, by association or by the more subtle emotions which may be evoked by arrangements of mass and line, the qualities or the significance of the thing commemorated. Heroic scale and simplicity, because they lend both dignity and permanence, are the most frequent attributes of monumental sculpture, and that idealization of forms and of attitudes which leads to the elimination of all that is ephemeral or mean is an almost universal characteristic. More than any other form of plastic art, monumental sculpture strives to express those qualities of structural truth, of harmony in mass and movement, which good architecture also embodies. A realistic or pictorial treatment, although often used for the decoration of memorials, is apt to be less effective for monuments which are intended to illustrate, not accidental or trivial aspects of nature but rather those heroic qualities of the human spirit that attest its enduring greatness. A romantic or symbolic treatment which depends upon knowledge or upon understanding for its appreciation and a purely decorative style which offers only sensual delight, are also unsatis-

fying in a memorial. That monumental sculpture is best that imposes upon natural human forms the architectural logic of mass and structure.

The desire to leave some record of his sojourn on earth seems to have been instinctive with man from the beginning, and no doubt this instinct is closely associated with his desire to represent the human form in stone or wood. From the earliest ages man seized upon the hardest and most enduring materials in which to carve representations of his own form. With the development of the first civilization, in Egypt, Chaldea, Mexico, these instincts found expression in a wide range of monumental sculptures.

Ancient Civilizations.—We shall omit a detailed description of the monumental sculpture of Egypt, Mesopotamia, Greece and Rome, since this is described elsewhere. (*See* EGYPT: *Archaeology and Art;* GREEK ART; ROMAN ART.) Both the Egyptians and the archaic Greek peoples set up in the precincts of their temples sculptured memorials which are concise and solid in character. After the end of the 6th century these monuments shared the growing naturalism of all Hellenic art: the memorial set up in Athens to "Harmodius and Aristogiton" (514 B.C.—copy in Naples) is an example. An equilibrium between naturalism and idealism is characteristic of the finest Greek memorials, such as the "Victory of Samothrace," set up in 306 B.C. to celebrate a naval victory. In the later phases of Greek sculpture, realism, to which are added dramatic and narrative qualities, becomes dominant, as the "Dedication of Attales I." (241–179 B.C.) at Pergamum, commemorating a victory over the Gauls, attests.

In Rome, memorial sculpture is almost always an accessory of architecture; but it is, nevertheless, almost wholly pictorial in character. The vigorous and realistic frieze which envelops in a superb spiral the column of Trajan (a war memorial set up in A.D. 113) is an example, as are also the fine reliefs of the arch of Titus (A.D. 71), set up to celebrate the capture of Jerusalem. The sculpture of the "Ara Pacis Augustae" (13 B.C.), one of the few monuments set up to commemorate a peace, are more idealized, as is also the contemporary "Augustus of the Prima Porta," one of the finest achievements of Roman monumental art.

The Middle Ages.—No sculptors understood more profoundly the principles and technique of monumental sculpture than the sculptors of the middle ages, particularly those of the 13th century in France, but since their greatest achievements were the sculptural ensembles of the cathedral portals, it will be more convenient to discuss their work at another place. (*See* section on *Architectural Sculpture;* also GOTHIC: *Art.*) We shall speak here only of a phase of their art less dependent on architecture: the execution of sepulchral effigies and tombs.

From the beginning the Christian Church marked the graves of her apostles and her martyrs with a stone or bronze memorial. The character of these did not at first differ from other contemporary memorials except by the occasional use of Christian symbols. The vast number of sarcophagi in Rome, executed for the most part after the reign of Constantine, illustrate the development of this Hellenistic art, in which classic forms and drapery, not without dignity and grace, are united intricately with the conventional decorative motives of orientalized Antioch or the *genre* detail of Alexandria. After the 5th century they share the technical decadence of Rome.

The revival of the arts under Justinian—and later under Charlemagne—found a wide expression in intimate sculpture such as ivory carvings and architectural ornament, but left few examples of monumental art. The bronze Easter column, set up it is said by St. Bernard, in the cathedral at Hildesheim is little more than a piece of constructed ornament. It was not until the 10th and 11th centuries, when the sculptor was called upon to decorate the new monastic buildings, that the monumental spirit was once more revived. Developed in the abbey doorways, where the sculptor had to learn anew the technique of stone carving and of rendering the human figure, this spirit gradually entered once more the sepulchral art of Germany and France. It is felt first perhaps in that form of tomb in which a sculptured figure of the deceased is cut or moulded on top of a sarcophagus or on the sepulchral slab let into the floor of abbey or cloister. Although these figures continued for a long time to be only flat reliefs scratched into the flat surface of the stone they are idealized and simple forms. When, after the 11th century, they begin to be carved in bolder relief and finally in the round, the figure is still conceived, as in the incised reliefs, in a standing posture, but laid on his back. The form is rigid, the head erect, and the draperies, unaffected by the change in position, drop in stiff, thinly cut folds from shoulder to feet. Germany was the centre for the production of these grave reliefs, which show a progressive development in technique. The relief grows higher and higher, the figure and the features gain steadily in idealism and in dignity, and the draperies show an increasing beauty of pattern and line. The series of effigies at Ovedlinburg, representing the abbesses of that monastery, illustrate this evolution.

The sepulchral effigies of the 13th century share those ideal and simple qualities which are manifest in the cathedral doorways, but the preoccupation of the sculptor with architecture prevented a wide or sustained development in this field. That development had to await the 14th century when the decoration of the architectural structure of the cathedrals seemed gradually less important than their embellishment with furniture, with retables and chapel screens, and with tombs wherein an individual patron, rather than a community, might be commemorated. This new patronage, which removed the sculpture from the geometric lines of the building, accelerated the growth of naturalism which can be traced more continuously in the tomb figures than in any other field. The body, laid at full length on the stone slab, begins to lose its rigidity. Its forms are clearly defined below the drapery which flows over it in an increasing complexity of fold. The features attain first a realism that approaches portraiture and then, as the influence of St. Francis permeates religion, they take on an emotional or sentimental quality. Accessories, symbols, details of costume and heraldry are rendered with greater and greater elaboration.

The tombs in the Abbey of St. Denis, near Paris (1264) built by St. Louis for his ancestors and his sons are characteristic examples of 13th century tombs. In these the figure is modelled not in relief but in the round. Each figure, represented as in early manhood, and rendered as a standing figure laid upon the ground, is graciously idealized. Each has a simple architectural framework, low in relief, and each is placed on a base embellished with pictorial reliefs. The expression is calm and benign and the draperies straight and simple with long clearly incised lines. The tombs for Rollo and William Longue-Epée, in the cathedral of Rouen (*c.* 1270), the bronze figures of Geoffrey d'Eu, in the cathedral at Amiens, are other interesting examples of these austere effigies.

Characteristic of the 14th century is the tomb of Charles V., at St. Denis by André Beauneveu; where the advancing realism of the century expresses itself in accurate portraiture and in more flowing and natural draperies. The figure is portrayed in the stiffness of death, and about him are grouped representations of his relatives in the costumes and attitudes of mourners. The fine tombs of the popes at Avignon—one of which is elaborated with a canopy—and the effigy of Robert d'Artois at St. Denis, clad in full armour with a lance in his hand, are other examples which illustrate the growing interest in actuality. In the 15th century, when this principle reached its widest acceptance, Flanders and Germany became the most important centres for sepulchral art. At Tournai there was developed the type of tomb in which the figure of the deceased, no longer dead and recumbent, kneels before the Virgin or some religious object; and these tombs, the production of which amounted to an industry, were exported to all parts of England, France and Germany, and widely imitated. The "Monument to Isabella de Bourbon" in the cathedral at Antwerp (*c.* 1465) and the "Tomb of Louis de Male, at Lille" (1455), both of which are of bronze, are characteristic examples of this Flemish art in which the elaboration of detail and the representation of action and of personality are clearly the preoccupation of the sculptor. Burgundy, which after the beginning of the Hundred Years' War became the sculptural centre of Europe, produced a funerary art not less realistic than that of Flanders. The famous Tomb of Philip the Bold (completed 1411) is an elaborate example of this art, in which the recumbent figure of the king is placed on a

SCULPTURE ON TOMBS

1. Tomb of Robert d'Artois in St. Denis Cathedral, France
2. Tomb of Cristoforo Felici, in the church of S. Francesco, Siena
3. Tomb of Philippe Pot now in the Louvre
4. Tomb of the Doge, Pietro Mocenigo, in the church of SS. Giovanni e Paolo, Venice
5. Tomb of Ferdinand and Isabella at Granada, Spain
6. Tomb of Cardinal d'Amboise in Rouen Cathedral
7. Tomb of Comte d'Harcourt in the Cathedral of Notre Dame, Paris
8. Tomb of Richelieu by Bouchardon in the Sorbonne, Paris

high pedestal elaborately decorated with traceries and with the modelled forms of draped mourners. The effigy is clothed in ample and flowing robes and at his head are the kneeling forms of two angels. German tombs, after the 13th century, are notable for their profusion of accessory and for the occasional introduction of narrative and action into the sculptured figures. Escutcheons are developed in Germany into elaborate decorations and early in the 15th century the baldachino or canopy makes its appearance here as in Italy. Ornate canopies are also common in 15th century England as are also the multiplication of angels, heraldry and symbolic ornament, and the realistic trend is so far developed as to lead to examples wherein the base of the tomb is left open to reveal the corpse within.

The custom of placing the tomb in a niche in the wall received wide acceptance in Spain and in Italy in the 15th century. In Spain these niches, framed in wide arches, received a lavish embellishment in which Moorish ornament frequently appears: the "Tomb of the Two Knights" in the church of S. Esteban at Cuellar and the "Monument to Archbishop Lope de Fontecha" in the cathedral at Burgos are examples. In the elaborate "Tomb of Juan de Padilla," by Gil de Siloé, now in the museum at Burgos, the effigy kneels before a relief of the Pietá against a background of delicate tracery. In Italy the influence of the antique and the example of Nicola d'Apulia is shown in the substitution of a sarcophagus, covered with figure carvings, for the northern tomb-base. The effigy, lying on this sarcophagus, is revealed by angels who pull aside sculptured curtains. In the more sumptuous examples a great baldachino, or marble canopy, supported by four piers, surmounts the tomb and is covered with a wealth of Gothic ornament. The three "Tombs of the Scaliger Family" (1350–74), in Verona, where the canopy is surmounted by a bronze equestrian statue, and the "Tomb of Mary of Hungary" (1325), in Naples, are examples of these canopied monuments.

The Renaissance.—The tombs of 15th century Italy are among the most perfect examples of that exquisite fusion of decorative architecture and classic sculpture which characterized this century. Although oftentimes greatly increased in size as compared to their Gothic prototypes, and most profuse in detail, they seldom attain a truly monumental character; they are, rather, accumulations of ornament, schematically arranged in a great niche set in the wall of a church. The vast Gothic churches of the Franciscans and Dominicans—S. Annunziata in Verona, S. Croce in Florence, SS. Giovanni e Paolo in Venice, for example—are lined with these tombs—the work of the Lombard ornamentalist—that contrast strangely with their laconic architecture.

A characteristic design for these tombs is that of an enframement of marble architectural forms—of arabesqued pilasters delicately wrought, with moulded and carved archivolts, entablatures and bases—enriched with statues placed in niches or in a pediment, and surrounding a sarcophagus upon which rests the effigy of the deceased. All parts of this enframement are exquisitely carved.

The "Tomb of Pietro Mocenigo" (*c.* 1462), by Pietro Lombardi in the church of SS. Giovanni e Paolo, Venice, is a superb example of this sepulchral art. The doge, in his robes of State, stands upright upon the sarcophagus, which is borne on the shoulders of three soldiers clad in classic armour. The "Tomb of Christolphe Felici" (1486) by Ambrose Lorenzetti, in Siena; the "Tomb of Leonardo Bruni" (1444) by Bernardo Rossellino, in S. Croce, Florence; the "Tomb of Carlo Marsuppini" (1455) by Desiderio da Settignano, also in S. Croce are other examples of this art that attains at its best a perfection of technique never surpassed.

In the 16th century, the Italian tombs lose this exquisite ornament. A more sober and studied style, in which scale, dignity and classic correctness are the ideals sought for, appears. The new feeling is foreshadowed in the almost perfect "Tomb of Ilaria del Carretto" (1405) by Jacopo della Quercia, in the cathedral at Lucca. The 16th century master of tomb design is Andrea Sansovino, whose "Tomb of Ascanio Maria Sforza," in the church of S. Maria del Popolo, Rome, takes the form and dignity of a Roman triumphal arch. The "Tombs of the Medici" (1523–34), in San Lorenzo, Florence, and the "Design for the Tomb of Julius II.," only partly executed, both of which are by Michelangelo, are the greatest examples of the mature and powerful art of this century. (*See* MICHELANGELO.)

The monumental sculpture of renaissance Italy was not, however, confined to tombs. Donatello revived the equestrian statue in his "Statue of Gattamalata" (1443–53) in Padua, bringing monumental sculpture into the open air and giving it once more a civic, rather than a religious significance. The "Statue of Colleoni" (1465) by Verrocchio, in Venice and the "Designs for a Statue to Francesco Sforza" (1506–10) by Leonardo da Vinci, followed. Michelangelo set his heroic figure of the nude David (1501) in front of the Palazzo Vecchio of Florence, while Niccolo Tribolo, also a Florentine, created the precedents in fountain design which were to be developed into the monumental fountains of the next century.

In France the renaissance created many decorated tombs of the greatest beauty among which the "Tomb of Cardinal Amboise" (1525) in Rouen cathedral, the "Tomb of Francis II. of Brittany" (1507) by Michel Colombe, in the cathedral of Nantes, and the "Tomb of Francis I." (1525) at St. Denis, by Pierre Bontemps, are perhaps the most celebrated. Jean Goujon, the greatest of French sculptors, has given us an example of his vital and gracious style in the "Fountain of the Nymphs," Paris; and Germain Pilon, whose work exemplifies the noblest classic tradition, achieves in his "Effigy of René Birague," in the Louvre, a most perfect balance between a sympathetic naturalism and monumental restraint.

The splendid "Tombs at Brou" (1505–26) near Bourg, built for Margaret of Austria, by Konrad Meit of Worms, are characteristic of the somewhat ornate renaissance of Germany, where the Thirty Years' War greatly limited the production of monuments. In Spain an army of Flemish and Italian ornamentalists, attracted by the prosperity which followed the discovery of America, embellished with sumptuous tombs the newly-built Gothic cathedrals, and founded with their Spanish pupils a school of decorative art which lasted well into the 16th century. "The Tombs of the Catholic Kings, Isabella and Ferdinand" (1517) by Dominico Fancelli of Florence, and "Doña Juana la Loca y Don Felipe el Hermoso" (1520) by Bartolomé Ordóñez, both of which are in the splendid Capilla Real of Granada cathedral, are two of the finest sepulchres of Europe. Other examples are the "Tomb of the Infante Don Juan" (1512) in the church of Santo Tomas, Avila; "The Tomb of Bishop Gonzalo de Terma" (*c.* 1525) by Diego de Silve, in Burgos cathedral; and recessed "Tomb of Enrique II. and Catherine of Lancaster" (1534) by Alanso de Covarrubias, in Toledo cathedral.

The Baroque.—No field was more congenial to the spirit of baroque art than sculpture carried out on a conspicuous scale. The baroque was a large style, delighting in impressiveness of heroic mass and deep shadow even when, in its effort to achieve a dramatic effect, it ignored not only structure and the laws of equilibrium but also that repose and dignity which in most ages have been considered the first essentials in monumental art.

The tombs of Bernini are magnificent dramas in which symbolic figures, clothed in sweeping draperies, with rhetorical gesture and expressive features, share in some emotional experience, theatrically depicted. An example of this virile art is the "Tomb of Alexander VII.," in St. Peter's, Rome. The pontiff, set in a great apse, kneels on a high pedestal about which Charity, Truth, Justice and Wisdom weep disconsolately while Death, a skeleton, raises the great draperies of polychrome and gold that veil a darkened doorway. The "Fountain of the Triton," in the Piazza Barberini, Rome, from which all clarity of profile or of shadow, all definiteness of plane, are removed, is also characteristic of Bernini's style, widely imitated throughout Italy.

The baroque monuments of France, less agitated and more gracious than those of Italy, are illustrated by the "Tomb of Richelieu," by François Girardon, in the Church of the Sorbonne, Paris. The dying cardinal, lying on his sarcophagus, is upheld by Religion and mourned by Science. The three figures, united by the lines of skilfully arranged draperies, are informed by a solemn and touching sentiment. The famous "Tomb of the Comte de Saxe," by Jean Baptiste Pigalle, equally allegorical, embodies in a

more theatrical composition, less sentiment and more symbolism. About the erect, dignified figure of the general, Death, France, Hercules, Eros and the Lion of England enact a spirited drama that overflows the architectural boundaries assigned to it.

The "Monument to the Great Elector," by Andreas Schlüter, a realistic and robust equestrian statue, is representative of the German baroque, as is also the periwigged "Apotheosis of Prince Eugene," by Balthasar Permoser in the Barok museum of Vienna. The baroque in Germany attained at times astonishing vitality and elaboration of form; the Trinity column, in Vienna, is an example. In England the baroque spirit is less understood. Of the many baroque monuments in Westminster Abbey, the best one, the "Tomb of Lady Nightingale" is by the Anglicized Frenchman, François Roubillac. Characteristic of the more fervid devotional sentiment of Spain is the "Pietà," by Gregorio Hernandez.

The 19th Century.—The 19th century witnessed an almost feverish activity in the building of sculptured monuments. A new type of memorial, that of a statue placed in a public place, replaces the intramural sepulchre, as the devotional and intellectual spirit of the baroque centuries gives way to the more national and sentimental feeling of the Victorian age. The neo-classic purity and coldness which dominates the first phases of 19th century art is slowly modified by realism and romance. France remains to the end of the century the centre of sculptural art.

"The Tomb of Clement XIV.," by Canova, in the church of SS. Apostoli, Rome, is a good illustration of early 19th century classicism. The composition is that of Bernini—the draped figure of the pontiff seated on his sarcophagus and mourned by Charity and Peace—but the dramatic action is replaced by a dreamy mournfulness, which is made impersonal by the generalized features, by classic draperies, and by the definite geometry of the architectural forms. The "Tomb of Nelson," by John Flaxman, in St. Paul's, London, while remotely derived from Pigalle, shares the dignity and classic restraint of Canova, which now become characteristic of all sepulchral art. The "Tomb of Queen Louise," in Charlottenburg, by Christian Rauch, is one of the loveliest of these neo-classic tombs.

The equestrian statue of Joseph II., in Vienna, by Franz Zanner, depicting the Austrian kaiser in the armour of a Roman general, illustrated the return to classic prototypes in street memorials. The "Cities of France," seated around the Place de la Concorde, in Paris; the graceful "Victories" which guard the tomb of Napoleon at the Invalides; the "Wounded Lion," at Lucerne, by Thorwaldsen; and the "Statue of General Washington," by Greenough, at Washington, in which the father of his country, half-naked, takes the pose and expression of Zeus, are other examples of neo-classic taste in monuments.

The nationalization of classic types, which was attempted by Thorwaldsen in his later works, illustrates that desire for national expression which the patriotism of the 19th century demanded. David d'Angers, called upon to create in the streets of French cities many representations of famous Frenchmen, not only gave these a contemporary costume but also gestures and expressions in harmony with their characters and activities. His "Corneille" at Rouen, "General Drouot," at Nancy, and "Thomas Jefferson," at Washington, are examples. François Rude shared this effort to nationalize French sculpture, as his "Marshal Ney," in Paris, demonstrates. Rauch, in his famous equestrian "Frederick the Great," in Berlin, not only renders realistically the costume and features of the king, but surrounds the pedestal with the portraits of his contemporaries. In America, John Quincy Adams Ward, in such monuments as the "Washington," in front of the sub-treasury in New York, succeeds admirably in adding a touch of national feeling to figures essentially classic.

The search for nationalism led inevitably to the revival of national styles. Carpeaux, in his spirited "Fountain of the Four Races," in the Luxembourg gardens, recaptures the pictorial warmth of French baroque masters; Jules Dalou, in his "Triumph of the Republic" and his "Silenus Monument" carries these tendencies still farther. Henri Chapu recalls in his "Tomb of Regnault," École des Beaux-Arts, Paris, the exquisite grace of Goujon, and the "Tomb of General Lamoricière," in Nantes, by Paul Dubois, illustrates also this tendency to turn to the national renaissance—a tendency equally noticeable in Germany and in Italy. In America this movement found expression in such admirable monuments as General Sherman in New York, by Augustus Saint-Gaudens.

Contemporary Monuments.—The period since 1875 has been prolific in commemorative art. This has been due, in part at least, to the development of realism and to the romantic and pictorial, and therefore popular, character which sculpture assumed towards the end of the 19th century. The growing tendency towards naturalism in monumental art, exemplified by the work of Rude, Carpeaux and Bayre, culminated in Rodin, whose "Monument to the Burghers of Calais" is the negation of classic form. The realism of this monument, which recalls that of the 15th century Gothic and its narrative and emotional power, have made it the prototype of a world of memorials both in Europe and in America. "The Monument to Victor Hugo" is less literal and achieves something of the strength of Michelangelo. The impressionistic technique and the "popular mysticism" which this monument exemplifies have also been widely imitated. Bartholomé in his fine "Monument to the Dead," in the Cemetery of Père Lachaise, Paris, embodies not only his freedom from the Hellenic rule, but also the realism, and the mysticism, the pictorial treatment, which Rodin had made popular. The monuments which continue the tradition are innumerable: the "Fountain of Time," in Chicago, by Lorado Taft; the "Burden of Life," in Harrisburg, Penn., by George Grey Barnard; and the lovely "Bacchanale," by Malvina Hoffman, are American examples. ARCHITECTURAL SCULPTURE

Architectural sculpture originated not only from the fact that something ornate was desired, but because practically all sculpture in the beginning had a symbolic meaning. Images of gods were wrought with their symbols, or the story of some great man's life was done in pictorial fashion, in bas-relief; and, as temples were built to enshrine these great deities, lesser symbols were gradually introduced to surround and protect the focal point. Man, with his instinct to invent and design, used these sculptures to enhance architecture with beautiful shapes and spacing.

Egyptian.—An interesting example of symbolic sculpture, known from the earliest periods to the present time, although its meaning seems to be lost, is the Gryphon, representing the elements. The wings, fins, blazing eyes, feet and body of the lion symbolize air, water, fire and earth. This was very often placed on the corners of the temples. Some of the finest pieces of Egyptian sculpture representing the deities were Ra, Isis, Osiris and, of course, the Sphinx. This is sculpture, architecture and symbolism knit together in a highly artistic and decorative manner. All these Egyptian works were powerful, massive and beautifully fitted to architecture, and to the great scheme laid out by the architects of that period. Their scale plan was enormous. Scale is one of the most important elements that an artist has to deal with, and this does not mean only the scale of proportion of one thing to another; the immensity of scale gives the onlooker a feeling of awe as well as beauty, whereas the small scale may simply appeal to his sense of beauty. The Egyptians felt how important it was to make their works of art in enormous scale. The Pyramids and the Sphinx carry what the designer wished to convey even after thousands of years. The Egyptian artists left probably the most impressive and awe-inspiring monuments yet erected in the world. The shape of the Pyramid at a small scale,

ARCHITECTURAL SCULPTURE OF EUROPE AND THE ORIENT

1. The Porte Royale, or central doorway of the Cathedral of Chartres, adorned with statues of royal saints, 12th century. 2. Kings of Judah, a group of 16 figures on the gallery above the Porte Royale, Cathedral of Chartres. 3. Middle portal of the façade of Notre Dame Cathedral, Paris. With the exception of the modern figure of Christ on the central pillar, the sculpturing (partly restored by Viollet-le-Duc) is early Gothic. 4. Detail of the façade of the Basilica of St. Mark, Venice, showing the famous bronze horses modelled by a Greek artist of the 3rd century. The façade, which is divided into two tiers of 5 arches each is pillared with marble and inlaid with scenes in mosaic. 5. The "Marseillaise" by Jean François Rude (1784–1855), on the east façade of the Arc de Triomphe de L'Etoile, Paris. 6. The Arc de Triomphe du Carrousel, Paris, erected (1806–07) by Pierre F. Fontaine (1762–1853) and Charles Percier (1764–1838) in commemoration of Napoleon's victories of 1805. Forty-eight feet in height, it is a reduced copy of the arch of Severus at Rome. 7. Panel by Jean Goujon (*c.* 1520–*c.* 1566) from the Fountain of Innocents, erected by Pierre Lescot (*d.* 1578) in 1550. In the Louvre. 8. View of the Huang Ssu (Yellow Temple), Buddhist monastery in Peking, China, showing the Pan Ch'an Lama Memorial built by Chien Lung in the 18th century. Designed on Thibetan lines, its marble sides are elaborately sculptured and it is surmounted by a cupola of gilded bronze. 9. Lion by Antoine L. Barye (1796–1875) in the Tuileries gardens. 10. Equestrian statue of the four princes in the great temple of Sri Rangam (built 11th–16th century A.D.) near Trichinopoly, South India

EXAMPLES OF ARCHITECTURAL SCULPTURE

1. Group in glazed terra cotta by Carl Paul Jennewein (1890–) for the pediment of The Philadelphia Museum of Art. This is part of an unusual exterior decoration scheme in polychrome in the manner of the ancient Greeks, conforming with the classic design of the building
2. Model of pediment by Adolph Alexander Weinman (1870–) for senate wing of Wisconsin State capital, 1912
3. Statue in front of the Custom House of New York city. Executed by Daniel Chester French (1850–)
4. Memorial to the Dead in the American Cathedral at Paris, France, Mahonri Mackintosh Young (1872–), sculptor. Bertram Grosvenor Goodhue (1869–1924), architect
5. Ornamental clock for the Grand Central building in New York city. By Edward McCartan (1878–)
6. Statue of George Washington by Alexander Sterling Calder (1870–) on Washington's Arch at Washington Square, New York city
7. "Music" by Emile Antoine Bourdelle (1861–) for the Théâtre des Champs Elysées, Paris, France
8. Central group representing Farel, Calvin, Bèze and Knox, designed by Henri Bouchard (1875–) and Paul Maximillian Landowsky (1875–), for the Reformation Monument at Geneva, Switzerland. Laverrière, Monod and Taillens, architects
9. "The Burden of Life and Labour" by George Gray Barnard (1863–). On the capitol at Harrisburg, Pennsylvania

say, 4 or 5 ft. high, has no element to make it impressive or particularly beautiful, but executed in the size of the Cheops, it is wonderful. Another example of the importance of scale is the Washington Monument, very striking in its present proportion, but which at small scale would not be impressive or particularly beautiful. The same thing may be said of a small hill that is the exact shape of a mountain; the mountain is impressive but the hill is insignificant.

The Egyptians made small sandstone models with the idea of carving the full size in granite, and these models were studied with that point in mind. Thoughts of carving were controlled by materials, and it is not usually realized what an important part material and tools play in the making of a national art. All primitive peoples have had very poor facilities for the making of things artistic, and this has left a decided stamp, usually of strength, simplicity and beauty, not alone in sculpture and architecture, but in rugs, vases and utensils. Egypt's great carvings are, as a rule, in granite or porphyry, the hardest of materials, which made it next to impossible to cut depths or to model suavely with the tools at their command; the result was the solid mass and beautiful architectural form that the stone more or less held after being roughly shaped. The difference is readily noted between the Egyptian and Greek carvings of capitals over the columns, the simplicity of the Egyptian and the growing complicated Greek orders from the Doric to the Corinthian. The natural idea in the beginning was to follow the known order of Egypt, but the material, being easy to manage, led to new forms of less simplicity and a corresponding elegance, which, however, lost in power and fundamental beauty.

An advantage that the Greeks and Egyptians had over the northern sculptors was in the fact that they could work constantly outdoors in loggias and patios. Michelangelo made the Medici tombs in the Loggia dei Lanzi, an ideal place to study the effect of light and shade, with the direct outdoor light falling on the figures. The light in that particular spot can best be studied where there is now placed the group called "The Rape of the Sabine Women."

Archaic Greek.—The Archaic Greek period was most fascinating and delightful; it had a certain wonderful grace, primitive and grotesque. It was playful, light in vein, and beautifully adapted to architecture; it seemed to fill a required space with a flowing richness of design incomparable, as in the Olympian pediments, for instance, although the modelling in itself does not approach that of the Parthenon groups, 500 years later. In the Olympian pediment, the massing of the volume of sculpture was placed beautifully over the capitals, allowing the darks to follow the shadows between the columns. The figures were interwoven in such a manner that there was a constant flow of light from one mass to the other, not a perfectly flat light, but a gradual tapering effect of light and shadow making a wonderful play of colour through the design. This moving effect followed from the end of the pediment straight up to the centre from both sides where figures standing erect stopped the movement, and gave a perpendicular feeling from the centre of the pediment through the centre of the façade. This same effect was carried out in the Parthenon, according to the drawings of Carrey, with a like result.

Greek.—From the Archaic there was a gradual development into the period which we know as the greatest in Greek art; at Athens, with its Parthenon and Erechtheum, many other wonderful works were being built. The Erechtheum is one of the choice bits of architecture of the world, with its superb caryatids, figures possibly the most closely allied to architecture of all the Greek period. Another superb decoration used on Greek buildings, which is now a criterion, is the acroteria (*q.v.*), which gradually developed into a most beautiful form. It is founded on a plant basis, with the use of a growing character which has a beautiful sense of proportion, subtracting all realism and creating a motif that is one of the greatest inventions of all sculptural decorations.

Three of the most wonderful pieces of sculpture used in connection with architecture that have ever been produced are the so-called "Ilissos," "The Fates" and "Theseus." The "Ilissos" is undoubtedly the greatest piece of modelling that has ever been produced by man. It may not have carried architecturally as well from a distance as some of the groups in the Olympian pediment, but one can hardly question the high standard of taste of that period and it was very likely perfect from all standpoints. The figures known as "The Fates" with their wonderful draperies are marvellous, beautifully designed and yet solid and monumental, and surely make a superb shape in the spaces for which they were designed. The two connected figures of the three "Fates" are infinitely superior in workmanship to and more beautiful than the detached third figure. It seems that only here and there one sees the touch on this figure of the master hand that did the other two. The group of two is so marvellously massed in plane and volume, and yet so perfectly drawn and designed that the layman might look at the group without realizing its geometric shape. It is made with three broad planes, practically flat, with the carving extending in and out in a very slight degree. Michelangelo has used this same method, cutting a block into triangular shapes, making a group of figures by drawing them on the three surfaces of the plane and carving into those surfaces, but leaving parts of the figure (draperies, etc.), to touch the surfaces in all the planes. This is particularly noticeable in his group, "Descent from the Cross." All great sculpture seems to have this feeling of volume, mass and geometric shape. It would seem that "Ilissos," "Theseus" and "The Fates" were the work of one man, but it is difficult to believe that they were done by Phidias, the several works known to be done by Phidias having a much more rigid character. There is a replica of a sketch which is called "Athene of the Parthenon," and was evidently a working model. This is tremendously robust and powerful in volume, but lacks that wonderful beauty which the previously mentioned figures have to the last degree. The sculpture of the Parthenon pediments varied greatly and must have been the work of numbers of artists.

From that period on, sculpture gradually became less virile and less fitted to architectural settings. Evidently the sculptors felt that they wished more realism and even went so far as to show textures in draperies, an unknown thing until this period. The Romans obtained Greek sculptors and required them to make copies of some of the finest of the Greek works of art. Many discoveries of such figures are still being made in Italy—a fortunate thing for the art of the world.

Italian.—Except for portraits, Roman sculpture was less interesting in every way than the Greek, and there was a lessening interest in architectural sculpture, which again came to the front with the Italian Renaissance period; and here again we have examples of some of the greatest pieces of sculpture known to the world. Such names as Della Robbia, Donatello, Michelangelo, Verrocchio are among the greatest, and the work they produced is close to the high-water mark. At this period, two of the greatest equestrian statues were made, the Colleoni and the Gattamelata. It is extraordinary to relate that undoubtedly these two characters would have been entirely forgotten to the world if Donatello and Verrocchio had not made them live for ever in enduring works of art. The statues, "Night and Day" and "Morning and Evening," on the tombs of the Medici by Michelangelo are among the greatest pieces of sculpture existing.

Gothic.—In all of the periods mentioned, sculpture followed the prevailing type of architecture: the long and low, or horizontal; the Egyptian, Greek or Renaissance type. A direct contrast to this style of architecture is found in that of the Gothic period, which, instead of following the line of the earth, reached into the heavens, and with the architecture the sculpture followed. Gothic sculpture is particularly attenuated and extended, the necks, body and legs of the figures being thin and long, but when viewed from the ground at a height of 50 or 60 ft., the figures seem to reassemble themselves and appear in perfect proportion. Apparently the figures were modelled by men who understood how they would look at a height, or possibly modelled in place, or at least tried in the position in which they were to be seen. In no other period has sculpture played a more important part than in Gothic architecture. It was used to embellish and colour, to give light and shadow to doorways and spires, and, in fact, the most

powerful effects of broken shadows were brought out by sculpture. Figures, animals and gargoyles were used as symbols as well as decorations in the Gothic scheme as they were in the Egyptian or Greek religions. A strange motif was the gargoyle, grotesque, with a sense of humour and a realism in spite of the fact that it is perfectly architectural in ensemble.

As an example of fine description of Gothic architecture, the following is quoted from Victor Hugo on the Cathedral of Notre Dame:

> Its front showed in succession and together: three ogive carved-in great doors; the embroidered and lace-worked ribbon-band of its twenty-eight niches for the statues of kings of Israel and Judah; an immense rose window flanked by two side-windows, as a priest is by his deacon and subdeacon; the high, frail gallery of trefoil arcades carrying a heavy platform on its slender colonnades; and finally, the two black, massive towers with their sloping roof-sheds. All these were the harmonious parts of a magnificent whole, piled up one above the other in five gigantic storeys, broadening out before the eye without confusing it with all their countless details of statuary, sculpture and carving, all powerfully "drawn in" to help along the quest of grandeur of the whole building. It was a vast symphony in stone, so to say, the colossal work of one man and one people, a complete composite whole like the "Iliad," whose sister it is. The prodigious product of a union of all the forces of an age, on whose every stone we see stand out in a hundred ways, the fancy of the workman disciplined by the genius of the artist. In a word, it is a human creation as strong and as fruitful as the divine creation from which it seems to have borrowed its double nature; variety and eternity. And what has been said of the whole church, of the Cathedral of Notre Dame, applies to all these Christian churches of the Middle Ages. All is contained in this, developed out of itself, logical and well-proportioned. If you measure the giant's big toe, you have measured the giant!

French.—Apart from French Gothic, we have a wonderful period of sculpture in France related to architecture. For a time there was a decided tendency to keep the sculpture from being at all realistic, resulting in a type that was very wooden in character. It was actually more architecture than sculpture, and there is always a moment when architecture and sculpture clearly meet. Sometimes they overlap; architecture becomes sculpture and sculpture becomes architecture, as in the case of the work of some of our present day modernists. "The Dance," for instance, on the façade of the Grand Opera House in Paris tends toward the realistic, yet it has perfect balance. The other groups on the façade are stiff and wooden in comparison. There is a story to the effect that when "The Dance," by Carpeaux, was put up, it was so hated that acids and ink were thrown over the marble. Discoloration can be seen to the present day.

The two types of sculpture are manifest in the Arc de Triomphe. The marvelous group of "The Marseillaise," by Rude, is very realistic in its movement and modelling, superb and courageous in its design, but it still holds its place in its architectural balance with such perfection that the other groups seem rigid, and so much like architecture itself that the fine, relieving note is lost. Yet, at the time these works were set in place, the less beautiful groups were admired as much as, if not more than, the Rude group. Now, there is no question in the minds of the artists and laymen which group of the Arc de Triomphe is the greatest.

The Louvre has its succession of fine pieces of architectural sculpture, among them some lions by Barye, and a beautiful pediment group by Carpeaux called "Flora." The bridges over the Seine in a later period come in for their share of architectural sculpture, but few of them have the solidity and power of the Rude and Carpeaux groups. They seem to be rather of the explosive type of sculpture, with broken silhouettes and flaring lines which weaken the groups to such an extent that they seem meagre and poor—particularly those of the Pont Alexander III. and also the groups on the Grand Palais near the north end of that famous bridge.

Rodin, one of the greatest French artists, was a superb modeller, with once in a while a sense of power and volume that tended toward making sculpture particularly architectural, but he was more often lacking in the sense of sculpture fitted to architecture. His "Gates of Hell" are famous mostly for the beautiful bits of modelling and design rather than from a sense of their fitness to architecture. It may be said of Rodin that he constantly demands that sculpture shall express moods and conditions which more properly belong to other arts.

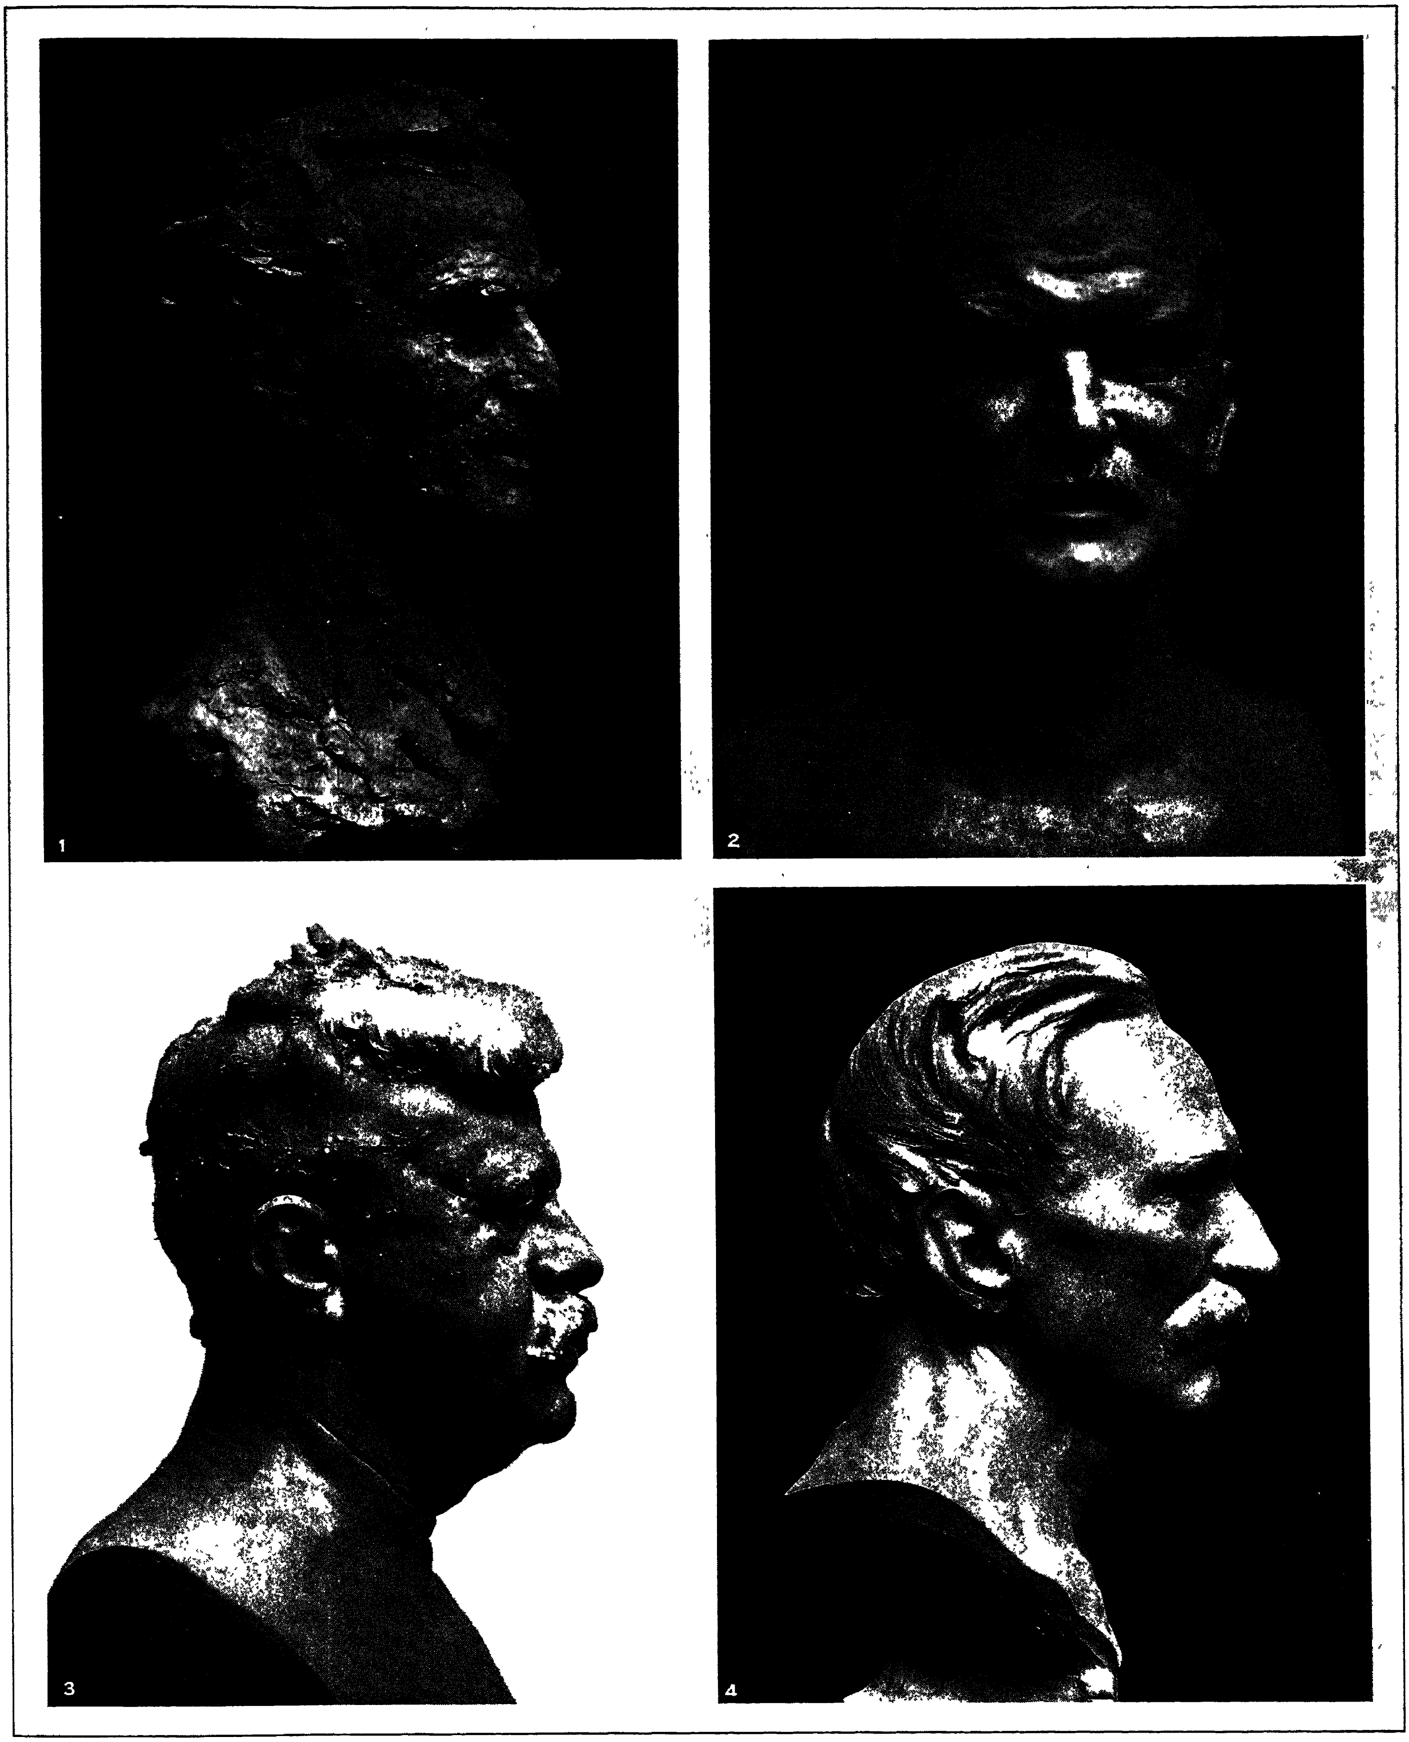
Modern Tendencies.—At the present time a type of sculpture is being used which more nearly forms a unit with architecture than anything that has been done for a long period. In America St. Gaudens had a fine sense of the relationship of sculpture to architecture. He was really a sculptor of monuments before anything else. His Adams memorial in Rock Creek cemetery, Washington, was fitted to architecture, although as a matter of fact it may be said that the architecture is fitted to the sculpture; as a whole it is a perfect combination. In front of the Custom House in New York city there are four fine groups by Daniel C. French. One called "Africa" is original and unusually architectural in its form, and is a high mark in sculpture.

It is interesting to note the changes in types of architecture. This has many causes, such as utilitarianism, climate, religion and geography. In New York it may be attributed to the fact that spaces are small and elevators are used so extensively. The buildings are carried into the air rather than along the ground, and the results have been a new type of sculpture. Other examples are the Nebraska State Capitol, the Kansas City war memorial, and nearly all city buildings. The sculpture seems to grow from the architecture into realistic forms of living things, either plant or animal, tending toward the modernistic types. Bas-relief is being used as much as it was used by the Egyptians. This keeps sculpture and architecture on the same plane, but it thereby loses in richness and a difference of plane which was sought after by architects and sculptors of the past. Even the figures which are supposed to represent sculpture in the round are flattened in parts, with the torso, arms and heads growing into the full round. Other evidences that architecture is meeting sculpture and that sculpture is growing into architecture is shown in the fact that architecture is becoming more fluid and sculpture more rigid. This may lead to something that has never been done before, but more likely this sameness of treatment will be detrimental to both architecture and sculpture.

With the possibilities that concrete brings to architecture and sculpture, there is only the hope that good taste will prevail to such an extent as to prevent art from succumbing to the ease with which this material can be used, making a period approximate to the one after the invention of the jig-saw, when all façades and front porches were made of ginger-bread design, owing to the facility with which the work could be accomplished. This tendency to merge architecture and sculpture presents the likelihood of missing something fine in not adhering to what Shakespeare speaks of as "excellent differences."

Composition is subtle and almost incomprehensible, but there are in all great sculptural pieces certain vital requirements. The first is volume, including shape; the second is the intricate lacing of the parts in rhythm; and the third and most vital is perfect feeling, or the co-ordination of the body into a whole. The brain can think one thought at a time; that thought makes the body one rhythmic gesture under the same central thought control. This follows through groups of people, as shown by the fact that the controlling person in a party is the moving power of all others; otherwise the individuals that compose a group of people are not perfectly harmonious. In an equestrian statue the horse must be dominated and controlled by the spirit of the rider. The great difference between the Colleoni and the Gattamelata is that the rider of the one is filled with verve and energy, which is reflected in the horse, whereas the rider in the other is philosophic, quiet and dignified, qualities also depicted in the horse that he rides. Any one of these vital points left out of the composition would mean that the work was not a masterpiece.

There is no end to the variety of conceptions if these themes are adhered to. What has been done in sculpture, as well as the other arts, is merely a scratch on the surface; those who say that everything has been done cannot visualize the untold possibilities of sculpture in its relationship to architecture. (*See* other sections of this article, such as *Decorative Sculpture; Monumental Sculpture:* also articles under SCULPTURE TECHNIQUE.) (J. E. FR.)



HEADS BY CHARLES GRAFLY ILLUSTRATING SUBTLETIES OF CONSTRUCTION AND COLOUR

1. Sketch showing how a smile affects the construction of all features. 2. Portrait which gives an impression of the size of the man by the careful treatment of the neck and shoulders. 3. Portrait showing treatment of fluffy blond hair. 4. Portrait showing treatment of dark hair turned gray

DECORATIVE SCULPTURE

Under the general heading of decorative sculpture is included all sculpture made primarily as decoration or part of an architectural scheme, or which is so designed as to fit into an architectural setting, or which, though not designed for any particular place, is yet so considered in its form relationships and harmonies of line and mass, that it becomes an abstraction in form of the object or subject represented. Thus it may be a work created in the artist's studio of the expression of some sculptural idea or emotion alone. It may be a large or a small work, a "Perseus Decapitating the Gorgona" by Cellini, a "Narcissus from Pompeii," or a small sculptured work from the Orient. It is rather a question, in the broadest sense, of the consideration of the subject of decorative sculpture, that it is the treatment of the form of the subject represented, the formalization or conventionalization of natural forms, rather than a strict reproduction of the forms of nature themselves that renders sculpture decorative. Thus it follows that all good sculpture is in a certain sense decorative, or at least has a large percentage of this decorative element in its conception. This discussion, therefore, does not involve so much a classification of a certain kind of sculpture as it does an element which should be present in all good sculpture. The sculpture of the Egyptian monument depicting gods, men and beasts is always fundamentally decorative. Each line and form is conceived in its relationship to those about it and to the architecture on the surface of which it is placed. It becomes at a distance a pattern taking its place in detail on the mass of the architecture, yet it may be emotional and dramatic in its intent, depending upon the imagination and the vigour of the sense of visualization of the artist. So, too, with the architectural sculpture of the Greeks. The pedimental groups and the frieze of the Parthenon are so beautifully proportioned to the architectural setting as to become an essential part of the architecture itself, and withal, a nobly expressed idea of high emotional quality, combining a spiritualized representation of natural forms such as has hardly been known in art. Gothic art (*q.v.*) is always decorative, whether it is of carved stone panels, tympana or figures of a 13th century cathedral, or the delicately chiselled bronze or ivory statuette. With Chinese sculpture (*q.v.*) it is practically the same and the carvings of primitive people are a formalized and therefore decorative representation of the chosen subject-matter.

Sculpture Arrangements.—A work of art always looks best when it is properly shown in the correct setting and when isolated and set off by appropriate surroundings. Our modern museums recognize this fact and their curators carefully study the lighting conditions, the texture and general quality of the background, as well as the association of one art object with another. So it is with a small bronze figure done by a sculptor of the Renaissance, not necessarily designed with a definite setting in mind, and though the sculptor did not know exactly what background was going to set it off, still he did so clearly have before him the general type of table, furniture or pedestal of the style of the period on which his sculpture was to be placed, that he could not well go astray. So a painter of that period painted a portrait or a subject piece for a patron without knowing the exact wall or place in which it was to go, yet he was careful to design the frame to surround it and make it in harmony with the picture. The sculptor designed the base or pedestal of his marble or bronze statue or statuette. The painter and the sculptor were generally architects as well, and the artists of this time began their training in what may be termed the applied arts. Thus the great artist was the flowering of natural genius which was to begin with natural craftsmanship and which had been trained in the application or association of art.

Sculpture was rarely created during the Gothic age except for a definite purpose or place and it was only with the period of Italian classical revival of the 15th century that began the flair of what is called "art for art's sake." Princes became collectors of art objects and it was not long before they began ordering painted or sculptured representations of mythological or other subjects and to build galleries to hold their collections. Even after this influence of the collector-connoisseur had been felt, decorative sculpture flourished in Europe through the baroque period and into the 18th century, where it found beautiful expression, especially as applied to garden sculpture, of which that at Versailles in France and of the Villa D'Este and at Frascati in Italy are examples. The decorative tendency continued on during the classical revival of Napoleonic times, but after that comes a period which lasted down to the 20th century, during which nature was copied in a photographic manner rather than formalized and interpreted, and the decorative sense in sculpture was to become almost completely lost.

Schools of Art.—In our own time comes a reaction against the naturalistic school and the beginning of a new classical revival, the Viennese secessionist movement being one of the leaders in this direction, and in Scandinavia, Germany and more recently in France, it is of vital moment. In this connection it would be well to mention the Decorative Arts Exposition held at Paris in 1925 where French decorative sculpture was magnificently shown, and where it revealed the many interesting tendencies and accomplishments in this field. Most other countries were represented by splendid achievements as well. This classical revivalist effort has not been especially coherent as it has lacked the direct traditional tendencies of the former periods of this nature because of the conditions of modern life which surround it and also because of the various other revolutionary tendencies toward which modern art is diverging. Cubism and post-impressionism (*q.v.*) have left their strong influence, and the fact that until recently and since the middle of the 19th century sculpture has been conceived and carried out as the interpretation in stone or bronze of a clay model rather than in the final material itself. Only now is coming the reaction against this tendency and there is an important school of sculptors who are working directly in the final materials of their art.

One of the factors at work in the world of modern art is the wide-spread appreciation of primitive art. Negroid sculpture, Polynesian woodcarving or Alaskan carvings in wood and slate have taken their place beside the ancient art of Egypt, China, India and elsewhere and have created definite impressions on certain schools of modern sculpture. These impressions are the result of the great publicity given lately to the interesting discoveries of what has heretofore been inaccessible. Naturally, in the handicraft of all primitive peoples the decorative element is strong. (*See* ART: *Principles of Art.*) Conservative art museums are devoting space to the exposition of these early decorative objects to a degree formerly unknown. Art dealers are exploiting it and critics are devoting much consideration to its qualities. A multitude of books devoted to the illustration of the objects has appeared within the last few years and the appreciation of primitive art has in some circles seemed to supersede that of the more highly developed classical kind.

There is a tendency toward a certain chaotic condition in some schools of modern art due to many causes, of which may be mentioned the lack of well defined rules of limitation, which bring about a mood of endless personal experimentation. Though sometimes interesting and promising of great things to come, and, in the hands of an artist of great talent, much sought after and appreciated, yet, because of their remoteness to tradition or because of their peculiar qualities, it is difficult to place these creations advantageously and make them fit into settings of modern life and appear in terms of what has heretofore been considered beautiful. For after all, and in the long run, art exists and will survive because it is beautiful, and when the contrary is the case the movement which brought it about will change or be short lived. Other tendencies of this lack of relatedness are caused to an extent by the fact that art is not as essentially a part of the life of to-day as it was in former times. It is a thing apart and not integral to our social order. Machine-made objects take the place of hand-made ones and the development of handicraft is not on the increase. Quantity production and standardization are a bugbear to the man who loves the beautiful artisan-created object. The variety and somewhat accidental qualities of hand-made work have a charm that the machine-made ones cannot reproduce, and a decorative work, though of original beauty of design and of

value as a unique piece, becomes undesirable when reproduced mechanically by the thousands—the Venus de Milo loses her charm as a cigarette advertisement.

Modern Tendencies.—Architecture, termed the parent of the arts, is beginning to arrive at a crystallization of certain well defined styles, more especially in America where restriction laws have dictated many of the new forms, and where the great height of the buildings has made it possible to use ornamentation in a new form. Self-imposed rules are coming into being and decorative sculpture is beginning to feel the influence toward an elimination of unnecessary detail and a reduction to pure line and form.

Other influences are being felt in modern art and sculpture in particular, as in the appreciation of the fleet lines brought into being by the swift moving automobile and the aeroplane lines of speed. It is the reflection of the spirit of our day in the language of the day, and it is ever changing and always fundamentally optimistic.

To sum up, let us say that the elements which are most essential to decorative sculpture are composition involving a pleasing distribution of masses, inherent beauty of line and form, and in which the open spaces between forms are as carefully considered for justness of shape as the forms themselves, and a rhythmic feeling between all associated parts from all points of view. These qualifications are age-old and have been appreciated by men from generation to generation.

Great sculpture is inherently decorative and in a truly great statue the inspirational or imaginative force that impels the artist to create and to give actuality of life to his work is that quality which arrests our imagination and makes us feel the spirit that is contained forever within the form of the marble. It is then that marble holds a throbbing soul and inner force. Afterwards the cold eye of appreciation is turned to the surface of the statue and knows the qualities which go to make up its superficial beauty and harmony, knows why the hand wants to touch it—for one of the primary appeals of sculpture is to the sense of touch and therein is one quality which painting has not as it appeals only to the eye. We conclude that in great sculpture the emotional and inner life quality comes first, then follows the sensuous feeling for form with its outward expression of harmony and decorative rhythms, which is always of secondary importance in the work of art.

MATERIALS

Terra-Cotta.—The sculptor of to-day works with materials very similar to those that have always been used. Terra-cotta or baked clay in one form or another is perhaps one of the earliest substances which man has attempted for artistic expression. Primitive races have made use of small clay figures. In Egypt and Greece, in India and China, the earliest civilizations have known this art and many beautifully modelled figures, glazed or unglazed, have come down to us through the centuries. The early Greeks executed sepulchral figures and sarcophagi in terra-cotta, of which the one in the British Museum is a fine example, and even heroic statues and groups, such as the group in the Villa Pope Julius in Rome from Veii, of Hercules, Apollo, and Hermes. Of these only the figure of Apollo is intact but there are fragments of the others. Terra-cotta or pottery was used in a masterful way by the sculptors of the T'ang and Sung dynasties in China. From Della Robbia all the way down through the ages to that flowering of masterpieces in this art of the 18th century many different styles and schools have brought it to a beautiful perfection. In primitive America the sculptured art of the Aztecs, the Mayas and the Incas was in a large part terra-cotta. (*See* SCULPTURE TECHNIQUE: *Terra-Cotta.*)

Why is it that this substance has persisted throughout the ages and what are its advantages? First of all, it is easily modelled and sculptors who are practising their art of difficult and tedious technique have been anxious to make use of a material which lends facility to their work. Another great advantage which terra-cotta has is that after being baked it becomes, with proper handling, one of the most durable of substances, not subject to erosion or corrosion. Finally, it undoubtedly appeals because of its possibilities in colour. The use of various toned clays and the possibility of the decorative effect arrived at by coating it with a brilliant or soft-toned glaze in a great variety of colours has appealed to many sculptors who feel the limitations of their art as practised in other materials in regard to colour. (*See* POTTERIES AND PORCELAINS.)

Bronze.—Bronze (*q.v.*) is a material which, though not used quite as early as the clays, came into the hands of man thousands of years ago. The Egyptians used bronze in making statues. It was also a favourite material of the Minoan civilization and the Chinese were masters of it in the third millennium B.C. As a material it has advantages similar to those of terra-cotta for the sculptor can make his original model in clay, in the same method as that used for the making of terra-cotta, and the process of casting is very little more difficult than that of firing terra-cotta. Moreover, bronze lends itself to easy and approximately perfect reproductions of the original model so that a number of copies can be made from the original. But perhaps the greatest advantage to the sculptor in the use of bronze lies in its tensile strength which lends itself to certain forms of expression quite impossible in stone, terra-cotta or any other non-metallic material. For instance a running figure may be so modelled as to touch the base with only the toes of one foot. Equestrian statues or figures of deer or other animals with slender legs can be beautifully treated in bronze and are strong and sustaining. An excellent example of this typical treatment may be seen in the statue of "Mercury" by Giovanni di Bologna or in a Quadriga group where the horses' reins and the finest of detail are executed in bronze. In addition to the advantages of this tensile strength are the advantages of finish permitting of the finest detail and considerable range of colour from pale brilliant gold or silver-like tones through the various greens, browns and even reds of the patinas which are natural to this substance.

Stone.—Marble and stones have often been thought of as the natural materials in which sculptors work, perhaps because of the fact that so many great masterpieces have been executed in them. (*See* SCULPTURE TECHNIQUE: *Stone Carving.*) Stone sculpture, though difficult in execution, has the quality of permanence which appeals in itself, and in addition it readily associates with architecture which makes such a considerable use of the same material. To the trained sculptor it is possible to make much more beautiful forms from a resisting material than from a soft one. The very resistance makes it necessary for the artist to have a more complete and well defined mental picture of that which he is executing. Soft material lends itself to the changing of volume but not to the perfection of vital form itself. It is undoubtedly this quality of hardness in jade which has led the Chinese to carve so many beautiful objects from it, and the Egyptians did their most beautiful work in the hard basalt and granite. These materials all have a fundamental structure which impose upon the artist considerations of compactness of mass and unity of form which in the final conception impress with their qualities of beauty.

Marble or stone also exists in many beautiful colours and represents better than any other substance the quality of human flesh. Its surface texture and its translucency as well as its colour make it the natural material in which to execute portraits of women or children where bronze because of its heavy colour would be inappropriate. It is especially too the material for garden groups or figures where it is desirable that the statuary stand out in contrast to a setting of verdure. (*See* section on GARDEN SCULPTURE.)

Wood and Ivory.—Due to the vulnerability of wood and ivory to climatic changes these materials can be successfully employed as a rule in comparatively small and compact arrangements, yet generally in Europe and in India and China, as well as with the primitive peoples, beautiful sculpture has been created in both materials. Of course, though those materials are easier to carve, the grain imposes another difficulty with which the sculptor must contend and it is in the turning of this grain to the purpose of the design and its execution that the artist must think. These substances lend themselves to polychromatic effects and to the application of gilding to their surfaces. (*See* SCULPTURE TECHNIQUE: *Ivory Carving and Woodcarving.*)

EXAMPLES OF EARLY DECORATIVE SCULPTURE

1. Carved prow of a Maori canoe
2. Egyptian lion, 4th century, now in the Vatican Museum, Rome
3. Grotesque aquamanile (water ewer) of bronze representing St. George and the Dragon, 13th century, England
4. Copper figure of Siva (post-Vedic god of Hindu Mythology), 18–19th century, South Indian
5. Bronze griffin, Campo Santo, Pisa, Italy
6. Crozier of carved ivory, French, 14th century
7. Saint Nicaise and the angel called "The Smile of Reims," two of more than 500 statues that form part of the decorative sculpture in the 13th century cathedral of Notre Dame at Reims. The statues are shown in restored condition after having been damaged during the World War
8. "The Descent From the Cross," a group in the Louvre, Paris
9. Ivory statuette "Virgin and Child," Gothic, end of 13th century

PHOTOGRAPHS, ALINARI

ITALIAN SCULPTURE, FROM THE 14TH TO THE 19TH CENTURY

1. St. John the Baptist by Donatello (1386?–1466). In the Museo Nazionale, Florence
2. Bronze fountain figure of boy holding a dolphin, by Andrea Verrocchio (1435–88). In the Palazzo Vecchio, Florence
3. Statue of Victory by Michelangelo (1475–1564). In the Palazzo Vecchio, Florence
4. Mercury by Giovanni Bologna (1524–1608). In the Museo Nazionale, Florence
5. Pauline Bonaparte by Antonio Canova (1757–1822). In the Museo della Villa Borghese, Rome
6. Perseus with the head of Medusa, by Benvenuto Cellini (1500–71). In the Loggia dei Lanzi, Florence

DECORATIVE SCULPTURE OF THE 20TH CENTURY

1. "Mare and Foal," bronze statuette group by Herbert Haseltine, English animal sculptor
2. "Deposition," wood relief by Ivan Mestrović (1883–). Yugoslavic
3. "Horse" by Carl Milles (1875–). Swedish
4. "Danae," bronze figure by Aristide Maillol (1861–). French
5. "Black Panther," by Mateo Hernandez (1888–), Spanish animal sculptor
6. "Hounds," by Wilhelm Hunt Diederich (1884–). American
7. "Woman at Her Toilet," bronze statue by Jane Poupelet. French
8. "Heracles Drawing His Bow Against the Stymphalian Birds," a group in bronze gilt by Emile Antoine Bourdelle (1861–). French
9. "Diana," bronze statuette (24 in. high) by Charles Despiau (1874–).

Polychromy in Sculpture.—One of the important elements in arriving at decorative effects in sculpture is the application of colour to its surface. In ancient times sculpture was generally polychromed. The savage people of practically all countries have liked to apply colour to statues of their deities, to the carvings used in connection with their religious rites, and to the masks worn in their ceremonials as well as to their architecture in general. The polychromy was usually in the nature of opaque earth colours, the principal tones used depending upon the country where found and the substances available, but with red and black dominating and white, yellow and green or blue used. The colour was applied in flat tones with usually no attempt at mixing or blending, and the quality of the vivacity of the idol or mask or other object was heightened by its use and the decorative effects of the ensemble intensified.

In Egypt, colour was generally applied to sculpture, and in particular was a feature of relief work. It was rather the colour effect that dominated in the picture than the shadow of delineation of the carving. In fact, one is inclined to consider the relief rather as a painting in which the drawing was made permanent by the carved and rounded outline. Here, too, unmodulated colours were used and often patterns and ornamentation were picked out with the brush rather than carved with the chisel. The sculptors of Greece followed the tradition of Egyptian polychromy and until Hellenistic times used colour in their statuary. Ornamentations in architecture were also painted but it was in the great chryselephantine statues by Phidias that the art of the use of coloured matter in sculpture reached its greatest expression. Here flesh parts were executed in ivory while an intarsia of gold and silver and ebony made up together with other materials the rest of the statue or group. It is master craftsmanship in the hands of genius of artistic expression. Early Greek bronze statuary was oftentimes gilded and silver was inlaid in the ornamentation of a robe or a fillet around the head of a statue. The eyes were generally done in colour of inlaid materials, giving an expression of great liveliness. With Hellenistic times in Greece and the increased tendency towards naturalism in sculpture, painting gave way and the Romans made less use of polychromy than the Greeks, although many statues have come down to us composed of different coloured marbles. The Gothic sculptors liked to paint their statues and the interiors of churches of that period were generally rich in colour. This tendency towards painting of statuary was maintained until the time of the Renaissance. But after the finding of excavated marbles from ancient times in Rome, which were usually without colour, and the general popularizing of collecting of antiques, sculptors gave up the practice which had formerly been usual. Chinese sculpture has always been characterized by its use of colour. One is sometimes inclined to think that they preferred to a greater extent the use of colour on their statuary than on their paintings themselves.

With the general influence on the moderns of the primitives in art it remains to be seen how and what will be the reaction. Indications are that interesting use will be made of the lessons learned and the ways indicated. And hand in hand with the most ancient of methods come those of the most modern. Chrome steel, nickel and aluminium are metals, the use of which has considerable decorative value. New methods of applying glazes and paints are in use in the industries of to-day and new paints and enamels influence our artists. New materials are being frequently invented which find beautiful use in the automobile industry, in the making of radio apparatus, and in many fixtures and objects of utilitarian purpose. Those serving the use of artistry and in the hands of the new school of craftsmen sculptors, it is to be hoped, will give to the coming age a brilliant addition to the use of polychromy and coloured materials in our art. (P. MAN.)

SCULPTURE TECHNIQUE. The following articles treat upon all the various mechanical techniques involved in the art of sculpture including Wood-Carving, Stone Carving, Ivory Carving, Terra Cotta. Further material will be found under the separate articles on BRONZE AND BRASS ORNAMENTAL WORK, LEAD IN ART, IVORY CARVING, WOOD-CARVING, TERRA COTTA, as well as the shorter articles on REPOUSSÉ, ENGRAVING, etc.

The theory of technique is treated under the general article TECHNIQUE IN ART and under the other individual articles preceding this section: Garden, Portrait, Monumental, Architectural and Decorative Sculpture; and it is necessary for the student to consult these articles as the techniques vary somewhat according to the application of the sculptor's work.

Further study of technique may be pursued in the articles or sections of articles on Greek Art, Chinese Sculpture, Japanese Sculpture, Indian Art and Archaeology, etc., as many of these articles, though written from an archaeological viewpoint, do nevertheless treat upon the techniques involved in the practice of these ancient arts.

WOOD-CARVING

Wood-carving consists entirely in a sort of elimination of parts obscuring the desired image. Although the mechanical process is simple, the training required by the carver before he can put it into practice is by no means simple. Firstly, the carver must have a clear idea of what he is about to carve; its shape and form have to be studied before he makes a cut. He must have long practised the use of his various tools; he must know how to conquer the very serious difficulty which the grain of the wood presents in every inch of his work. Many years of laborious practice at last enable him to master all these problems. Of course there are many cases in which such skill and knowledge are neither to be found nor expected, as for instance in the case of primitive work, where a kind of child-like naïveté compensates for the lack of skill. The more sophisticated carver is not content to stop at this stage; he experiments with new forms, invents new tools, and slowly builds up a coherent manner of work which embodies both knowledge of form and skill in the use of his tools. From beginner to master, from generation to generation, this goes on, and so shapes itself into a dignified art—an art which demands a keen love of beautiful form and a constant pleasure in the use of the creative faculties.

Acquiring Technique.—Two kinds of knowledge therefore are essential to the wood-carver. A knowledge of form and a knowledge of and skill with his tools. The beginner must learn to cut before he invents anything for himself. The grain of all kinds of wood runs in a fairly straight direction, but the cuts made by the tools go in every possible direction. This difficulty has to be cunningly mastered by subtle movements of the tools; it takes at least two years of constant practice before one has thoroughly mastered the art of "cutting."

When a carver begins to learn the use of beautiful forms those forms are to him never the precise counterpart of nature's forms. He has been long enough at his craft to have learned that purely natural shapes and forms are inexpressible in wood, and that his only chance of making his subject readable is to adopt the traditional "convention" in his treatment, wherein he must simplify all his forms, arrange them in agreeable groups and make the very most of the strong contrast between light and shade of which his subject may admit.

Up to this stage the carver has been learning what may be called the technicalities of his craft, and perhaps exercising his mind in getting a useful knowledge of form. In this respect there is probably no difference between the education of a mediaeval and a modern carver, but here the modern carver is often expected to remain satisfied, and to go on carving, not what he would himself like to do, but what he is told to do by others. An architect, "builder," or some patron of art may give him a "design" to follow—none of them, probably, knowing anything about the use of carving tools. A handicap like this puts a full stop to the progress of the craftsman; he ceases to think of his craft in any other way than as a source of livelihood, and thus the innate talent of our wood-carvers is lost. This was not so in the case of the mediaeval carvers. There can be no doubt that there was someone to guide the work going on in the shop. This would be in all probability the master carver who controlled but did not fetter. This will be clearly seen by a reference to the illustrations, showing work of 14th and 15th century carvings. Such work could not have been done by fettered hands. Here fancy is seen to play within well kept bounds—the best treatment for a given position

has been decided by actual experience, be it under a *miserere* seat, on a stall division, or the orderly arrangement of a rood screen. This delightful playfulness of fancy has disappeared from our workshops, and instead of invention, spontaneous and living, we get miles of some stupid kind of "ornament" generally copied mechanically. It would be rash to look for an early change for the better in this respect, but there are some signs of improvement.

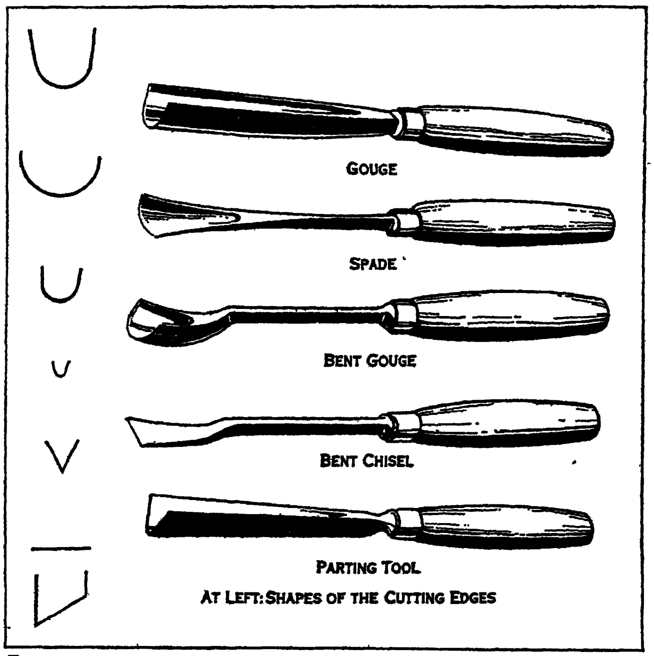

FIG. 1.—A FEW OF THE MORE COMMON SHAPES OF CARVERS' TOOLS WHICH ARE MADE IN MANY SIZES AND SWEEPS OF EDGES

Many architects are now trusting their carvers with more liberal freedom in the execution of their instructions, a movement which must have a good effect on all the workmen in the shop, where, as a rule, the manual dexterity of the carvers is in every way equal to that of their ancient predecessors, but where they seldom find much encouragement for their inventive faculties.

The Wood-carver's Tools.—The tools most commonly in use consist for the most part of chisels and gouges. They vary in size and shape. The gouges may run from $\frac{1}{16}$ in. to over an inch in width and have a variety of "sweeps" or curve of cutting edge: the chisels likewise are of different widths, and they are in three or four different forms, "straight," "bent" and "corner" (*see* fig. 1). The number of tools which may be used by a carver varies of course in accordance with the work he is doing; sometimes he will use half-a-dozen, sometimes more, these being a selection from his whole set which, in itself, may amount to several hundred. When the tools are in use, they are laid beside the carver with their cutting edges towards him in order that he may quickly pick up the one he wants.

These tools have to be kept very sharp and this requires great skill and care on the part of the carver. Blunt or mis-shapen tools cannot be used with effect. The stones he uses for this purpose are of various kinds. Some use "Turkey," some "Washita," but there are many more, including artificial stones such as Carborundum. For the inside of gouges "slips" of these stones are used shaped to the curves required, and for fine or very small tools a slip of "Arcansas" is used, a thin slip of very close texture. As a rule, soft wood like pine, requires a sharper tool than the hard woods like oak. Therefore tools used for this kind of wood are sharpened with a more acute edge. Both sides of a carver's tools are rubbed to a bevel, that which rests on the wood being the longest bevel. The inside only receives enough rubbing to produce a clean cutting edge. Some other tools are shown in fig. 2. The mallet is used for the heavier kind of work, where forcible blows are wanted, but mostly, for the lighter use of his tools, the carver uses the palm of his hand as a mallet when such is required. The bench screw is passed through the top of the bench and screwed into the lower side of the wood, which can thus be turned about on the bench; the use of the cramp is obvious, but there is a larger one known as a "bench holdfast" for thick wood which cannot be cramped to the bench. A carver's bench must be of very firm construction to remain steady under blows and sideway pressure. It is generally about 3 ft. 2 in. high and of a length and width suitable to the space he has at command: it should have the light in front of it, never over it. The benches in a carver's shop are often of considerable length as much room is required for long pieces of wood.

Woods Used in Carving.—The woods in common use are oak, yellow pine, and limewood, but many others are used in a less degree such as mahogany, walnut, chestnut, and for small articles box, pearwood and cherrywood. Teak is sometimes carved but it does not compare well with oak. The choicest kind of oak for the carver is English oak, as its texture is hard and close and its colour is beautiful. Next to this comes the Austrian oak which cuts freely but is not so close in its grain. The American variety is not so good for the carver's purpose; it is caney in texture and unpleasant in colour. Chestnut is not much used for carving but it might have a wider acceptance because it is very like oak and cuts well under the tool. This, of course, is the "Spanish" or "sweet" chestnut, variety. Mahogany likewise is not much used, except for very inferior work, where it is always French-polished. Mahogany, though, may be very useful wood if properly treated; if it is left unpolished, or simply waxed, it in time takes on a very beautiful colour but passes through stages of unpleasantness before that arrives. It is a good wood for figure carving which is intended for painting and decorating. For furniture or other work which comes close to the eye there is no better wood than Italian walnut; the most delicate carving may be done upon it. The "American" walnut and "French" walnut are much used for smaller work, but are not very amenable to the more delicate touches of the carver. Limewood is mostly used for figure work which is intended for decoration, although sometimes left in its natural state, as in the work of Grinling Gibbons.

Methods.—Having drawn the outline of the work in hand upon the wood the carver proceeds to make a groove all round this outline with a gouge of small size called a "fluter." Then he takes up a fairly large gouge of quickish curve and with it digs out all the wood between the standing parts until he approaches the depth he

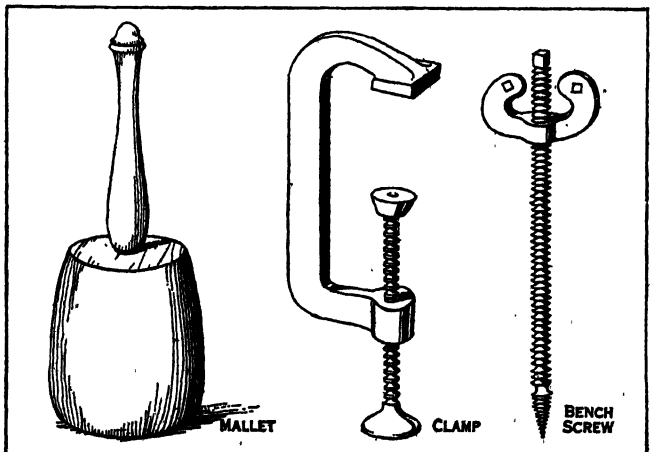

FIG. 2.—WOODEN MALLET, USED ONLY FOR HEAVY WORK; CLAMP AND BENCH SCREW USED TO HOLD WORK FIRMLY ON BENCH

requires. Then with a gouge of flatter curve he cuts down the sides of the projecting parts until they are nearly upright. His next movement is towards a more complete realization of his design. He begins to indicate the positions of veins, lower parts to their respective planes, and in general tries to put in the first stage of any detail such as the articulation of a leaf, berries, tendrils, etc., but all in a tentative way, leaving sufficient wood around every part to allow of little amendments as the work develops. This process, up to the point he has reached, is called "bosting in," that is, getting his work into a rough state of readiness for the "finishing." This is considered the most important part of

the work of a carver. The work, when it has been through this process of "bosting in," should be so suggestive of the final stage that it is not difficult for a skilful carver to realize completely all that is meant by the more or less rough details in it. The "finishing" is the clearing up of details by completing the contours, levelling the ground, making mitred corners, and should, if properly done, include securing a pleasant texture which may display the quality of the wood.

The foregoing applies to work in moderate relief. Low relief carving or very high relief requires a somewhat different treatment. Low relief requires in the carver a very high level of knowledge in the matter of drawing, because it depends so much upon the way in which its leading lines are disposed. Not less important is the management of the surface contours, and as in low relief not one of them can be even approximately true to the real form of the object represented, it follows that the contours must be delicately graduated so as to suggest roundness where it does not exist (at least to the same extent). All this means in the carver good draughtsmanship, and a very keen sense of form. In low relief, therefore, there is very little to do in the way of "bosting in." It is mostly sharp cutting and drawing with the tools.

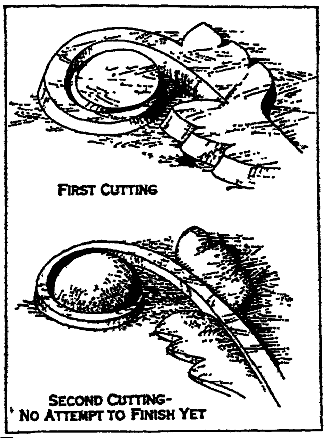

FIG. 3.—STEPS IN CARVING A DESIGN: ABOVE, DESIGN OUTLINED AND WOOD AROUND IT CUT AWAY; BELOW, MODELLING STARTED

High relief carving, or carving in the round, demands much knowledge of form on the carver's part. Let us suppose that he is carving a head; he must know to a nicety and by heart the exact proportions, the position of each feature and he must find these details by a process of clearance which is very confusing. Figure carving in a modern shop is often done as a divided labour: that is to say, one man makes a model and another man carves it. This is done by means of an instrument called a "pointer" which is so made that a measurement can be taken on any part of a modelled surface and transferred to the wood in exactly the same relation to a registered mark on each. By this means little points are made all over the surfaces which have previously been "blocked out," that is, carved down to within a quarter of an inch of the true surface. When some hundreds of these points have been made the whole surface is carved true between them. Such mechanical workmanship cannot have the most interesting results, but it saves time and eliminates the chances of failure and so is much in favour.

A word or two may be said here as to figure-carving in general. There can be little doubt that when figures were being carved for the decoration of churches in ancient days they were carved with the full intention of completing them by covering them with paint and gold. That this was so, many examples testify and often where the painting has disappeared traces of such still remain. So many met with this misfortune that it gradually became the custom for carvers to copy them as they saw them, that is, without decoration, so that in modern times figures have seldom been decorated in the old way. The result is that they are not often seen in such a good light that their lines or features can be properly distinguished. Wood always has a way of hiding itself if the lighting is not very strong, but the moment it is covered with gold and paint it reappears in all its details even in a dark recess. Nearly all the carved woodwork of ancient times was decorated with paint and gold, that is, of course, in all cases where it was safe from rubbing. Stalls or other church fittings which were liable to rubbing were never painted.

Modern Decline.—The outlook, from a wood-carver's point of view, cannot be said to be very encouraging at the present time. Ever since the beginning of the 19th century, the output from the carver's shop has steadily declined. It has ceased to be used on household furniture, and for domestic architecture such decoration is no longer required. Shops, railway stations, restaurants and some public buildings still make use of wood-carving, but of no artistic merit. The church seems to be the only sanctuary of the art, and there a better kind of carving may be seen, though never on the scale of importance which it once had. No doubt the cause of the decline is to be found in the increasing use of machinery and the enormous advance in the cost of labour. It is difficult to see in the face of these formidable facts what can be done to preserve the craft. It is not an art that can stand by itself; detached pieces of wood-carving, however good, are no more than toys. The danger in making such a use of wood-carving lies in the fact that it is under no restraint; there is no necessity for discipline, and such unlimited freedom leads mostly to a mere seeking after novelty, both as to motive and execution.

(G. JA.)

STONE CARVING

To a sculptor, in the true sense of the word (*sculpere*, to carve), a knowledge of the nature of marble is essential, for in marble he visualizes his finished work. However, it often happens that he is ignorant through lack of previous training of the very corner stone of his education as a sculptor, and has to entrust the execution of his work to men, who, though skilled in the art of carving, may not possess the artistic fire of the creator. There is a distinction in the words *sculptor* and *carver*. Michelangelo was a *sculptor*, because he wrested his creations from the stone with his own hands; the artisan, who copies in stone from the model given him by the artist, is a *carver*, who, often, may not have any knowledge of art, and works to the best of his mechanical ability, upon the work entrusted to his skill.

Marble, because of its texture and consistency, as well as its workable qualities, is the stone best suited to the needs of the sculptor, and for the sake of his art he should be taught early the nature of it, and the way of using it. It is as essential as the academic studies of geometry, perspective, anatomy and form (for Nature herself created it for her glory).

How to Begin a Statue.—In preparation of the finished masterpiece a model of the work on a small scale is essential, either in wax or in plaster. From excavations, years ago, it seems that even the ancient Egyptians made models in plaster, for when a room was unearthed, which seemed to be the studio of an Egyptian sculptor, many sketches in plaster were found in a good state of preservation, as well as casts from life of faces, etc., and all the necessary instruments for the pursuit of his art.

The Etruscans, too, knew and made models in plaster, as well as the Greeks, and certainly, the Tuscan artists of a later day. The model itself, however, is nothing but a sketch, an idea, which must later complete itself under the chisel, upon the marble.

After a little familiarity with the subject it is possible, by means of a few points and measurements, to give form to a marble statue; with the help of a small sketch a life size statue may be executed, or one even larger than life, by beginning with the gradual indication of the lines and principal reliefs. For this indication it will be necessary to use pointed tools. Then with the aid of compasses, measurements are made between the small model and the marble block, to make sure that the finished work will be done in accurate proportion. The statue to be executed is then blocked out in form, always with the help of the pointed tool, taking care to make the indications parsimoniously, though fearlessly. When the pointing is satisfactory, with just regard for reliefs and accurate values, a dented chisel is used, care being taken that the work is done always with due regard for the whole, and avoiding isolating the more fragile details when they are not closely linked with the principal form. This first work on the stone must be maintained at only one value, and care must be taken that no deep cavities are made, which might prevent the making of possible slight changes. When the statue has reached this state, the main plan of the finished work being clearly mapped out, it is placed upon a turning table that is at once manageable and very solidly constructed, so that the blows of the hammer will not cause any oscillations. Approaching the block with

greater precision, the sculptor next begins the main work, starting with the head of the statue. Unlike modelling in clay, wherein from the small one proceeds to the larger and main object, in sculpture one starts with the whole and gradually arrives at the achieved statue as the artist had planned it. For this reason it is necessary upon beginning to work on the model with hammer and dented chisel, to approach with caution and precision toward the release of the final forms. Geometrical working, upon the principles of right angles and squares, has ever been the method of the great masters.

When the head of the statue presents a just value with the whole, and is well allied with the neck, the sculptor proceeds upon the torso and arms, without losing sight of the general plan and construction. Indeed, the whole is ever borne in mind, and no given part is ever dwelt upon at the expense of another. Thus an equal tone is maintained, and harmony achieved in every form and value.

This method seems to have been the one adopted by Michelangelo, Donatello, Jacopo della Quercia, and the brothers Pisano before them, who have left sound traces of their labour.

The Greeks.—Nothing definite has come down to us of the system employed by the Greeks, but all their works show beyond a doubt that they were primarily master carvers on stone. Of course, even they had to make use of sketches in plaster to embody the original form of their creations, but Parian and Pentelic marble, of which the most famous museums are full, was the medium of their divine art, and never was the medium better employed and immortalized. The work of the Greeks was the product of the *bottega.* Every artist's studio was a school; academies with definite programmes did not exist. At a tender age the future sculptor exercised himself in working upon stone and marble, and this was the first step in his art. Then he drew and modelled under the supervision of the master, who, with paternal love guided the hand of the student and developed his intelligence. From the simple plane to the minutest decorations the students advanced. Often they worked hand in hand with the master upon his statue, and thus they developed into artists —carvers and sculptors.

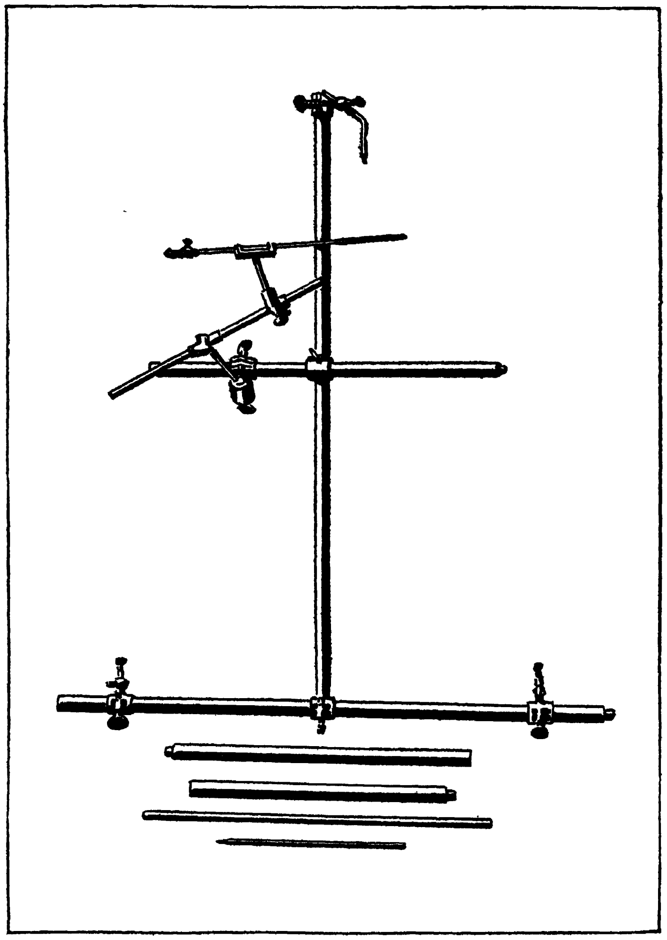
In this fashion were created the masterworks of the past. The Parthenon, in which sculpture and architecture are united in one glorious harmony, is the expression of the highest art. Pheidias, the sculptor, worked hand in hand with Ictinus, the architect, and under them a legion of master carvers wrought on the Parian marble reliefs, statues and groups that are a glory to this day. Take, for example, the great relief that covered the wall of the inner portico; it was the chisel of the carver that glorified it. The artist, indeed, contributed in the conception of the work with sketches and designs in charcoal upon the marble; but, working on relief and background, it was the carver that left his impress upon it. A study of the friezes in the Parthenon shows, by its unequal quality, that the carving was executed by various hands: some groups present all the perfection of the Pheidian hand; others, though still of a high order and holding their own with dignity, are lacking, however, in the precision noted elsewhere. Nevertheless, a small fragment of any Parthenon frieze would be enough to build the reputation of an artist.

Michelangelo.—It is well known how Michelangelo created his *David.* Already the immense block of marble that he used for his statue had suffered sacrilege by the tools of another sculptor. To Michelangelo was granted to create therefrom a miracle of sculpture. The marble was placed upon a pedestal, a house was erected about it, and the artist gave himself up to his task. A sketch was made, smaller by one-tenth, finished in all the minutest anatomical details. From this, with the help of scans and measurements, with carving and reliefs, Michelangelo wrested out of the stone his immortal work, made possible only by the daring of his youth and the supreme mastery he had over his material.

Upon observing the works of Michelangelo it often seems as though the rough and varying form of the raw block of marble as it came from the quarry gave to him the conception of the figure and group. This is more apparent in the four statues of the *Slaves* which were brought to light not many years ago. In two of them in particular are still to be seen the planes and cavities as they were wrought by nature in the marble quarry.

There is also the *Madonna de'Medici,* created in Michelangelo's maturity and which seems to have attained the apex of an artist's and carver's potentiality, both in the largeness of conception and the compactness of form, insuring solidity. No particular of the work is isolated; harmony is maintained throughout. Yet even in this group is to be found the suggestion of the mountain. The principal line has still the imprint of the natural plane, and religiously Michelangelo seems to have maintained it, even though he made it serve the purposes of his group: it is the line that descends from the right shoulder of the Madonna to the sole. It is also to be observed how well allied he kept the foot of the Child in its firmness and strength, making every detail serve toward the ultimate harmony of the finished statue. Only through thorough cognizance of his substance and a mastery of his tools was it possible to the artist to achieve his perfection.

Modern Methods of Carving.—With new times and new civilization have come other methods and ideas in all things, as well as in the method of carving. Under present conditions any young sculptor could become a proficient carver if he devoted a little of his daily time to this art. The problem of his existence would



POINTING MACHINE FOR TRANSFERRING POINTS FROM THE WORKING MODEL TO BLOCK OF STONE

be solved, for if it is too difficult for a young beginner to find in himself statues and monuments to be erected, he can easily manage to gain both experience and a livelihood by learning how to carve marble.

With the help of a pointing machine the present mechanical system of carving is easy to learn and free of responsibility because it is mathematically exact. Let us imagine that a statue is to be carved; the marble block is acquired and brought to the studio, then upon the model is applied a cross with three points, one of which is in the shape of a hook to support the

armature of the cross. The three points are of iron or brass, needle-shaped, which will find a place to receive them, also of metal, in the model or plaster mould. Upon the cross there is a movable armature, easy to manipulate, and revolving to the desire of the carver. At the extremity of the instrument there is a needle, the point of which will be approached to the model. At first, that is, for the primary blocking, the needle will not be made to touch the model, but will be limited to approach within an inch of it. The cross will then be placed upon the marble, and the needle will be guided until it touches the point already marked. For the primary roughing out, given a statue six feet in height, a point every six inches should prove sufficient; for the rest, the good sense and accurate eye of the manipulator will be needed. When the statue has thus been dealt with in attaining its first form, the pointing is done anew. Even this second time it is advisable not to go to the final points; for the beginner it is better to make an approach of approximately one-third of an inch, leaving the rest for the final pointing. (It is also advisable for beginners not to employ too many points or measures, but rather to content themselves with placing these indications upon the highest reliefs, marking each with the maximum of neatness and assurance, each point being given its own proper plane, before designating with the metal needle the final point.)

The tools used are chisels, plain and dented, and points of various sizes. They must always be clean and sharp; clean, too, must be the statue, in whatever stage of work. The marble must be cut in good, clear light, that the forms may always be well defined. The carver then examines his work from different aspects and by various lights, seeing to it that the surface of the statue is free of little undulations, and that the plane is clean, almost smooth, so that it may attain positiveness.

Later, that the true beauty and colour of the marble may be brought to light, the statue is washed with sand and rubbed with burlap or any cloth of rough texture. If a higher polish is desired, the marble is rubbed with either natural or artificial pumice stone for a long time, clear, clean water always being used. The marble is then washed with oxalic acid which has been reduced to the consistency of table salt, applied with a damp cloth to the surface, and rubbed vigorously. Care must be taken that no quantity of the acid remain upon the statue, for it is injurious to marble.

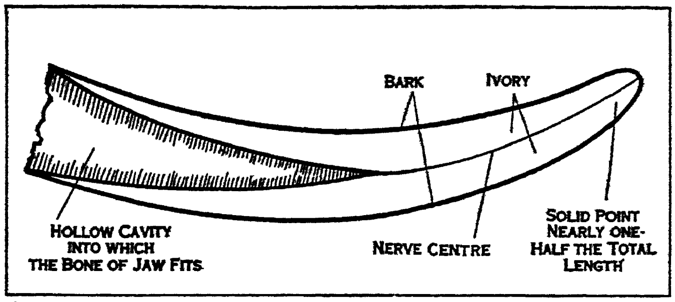
(There is, of course, the danger of refining to a fault, until the stone loses the qualities of its own peculiar nature and seems soft and weak to the eye.)

Bernini was among the first to finish his statues with the maximum of precision and care as to detail. Afterwards Canova, taking advantage of all progress and improvements made in the art of sculpture, was assiduous in giving his work such a quality of refinement that his carvers often went to extremes. Under them the qualities of the past masters were not taken into consideration, so that in the meticulous refinement that resulted from their labour the marble often had the semblance of majolica.

That which is best in sculpture never makes one forget the origin of the art, from *carving* on stone, as the Egyptians carved it, and the Greeks, and the masters of the Renaissance. The most important equipment of a young sculptor should be a knowledge and a love of the mother stone, which immortalizes the artist's greatest dreams. (*See* also SCULPTURE, and other sections of this article.) (A. P.)

IVORY CARVING

The Material.—In approaching the subject of ivory carving it is necessary first to consider the material in so far as it concerns the carver. Ivory, strictly speaking, is the tusk of the elephant: the tusk being the upper incisor tooth. For practical purposes the term must be allowed to include morse or walrus ivory, hippopotamus ivory and even certain kinds of bone and horn. The best ivory comes from tropical Africa. Asiatic ivory is whiter, more opaque and somewhat softer. The tusk is hollow at the end where it joins on to the jaw-bone; the walls gradually become thicker until, at about half the length, the tusk becomes solid; from here to the tip runs a nerve centre which shows in the cross section as a black spot; the tusk is covered with a rough bark of a hard pithy nature, brown on the outside and greenish white within; the thickness of the bark varies with the size of the tusk from $\frac{1}{16}$ in.–$\frac{1}{4}$ in. or so. The whole of the bark must be removed in carving. Seen in cross section the tusk shows a number of minute intersecting tubes radiating from the centre outwards, giving rather the appearance of engine turning on the back of a



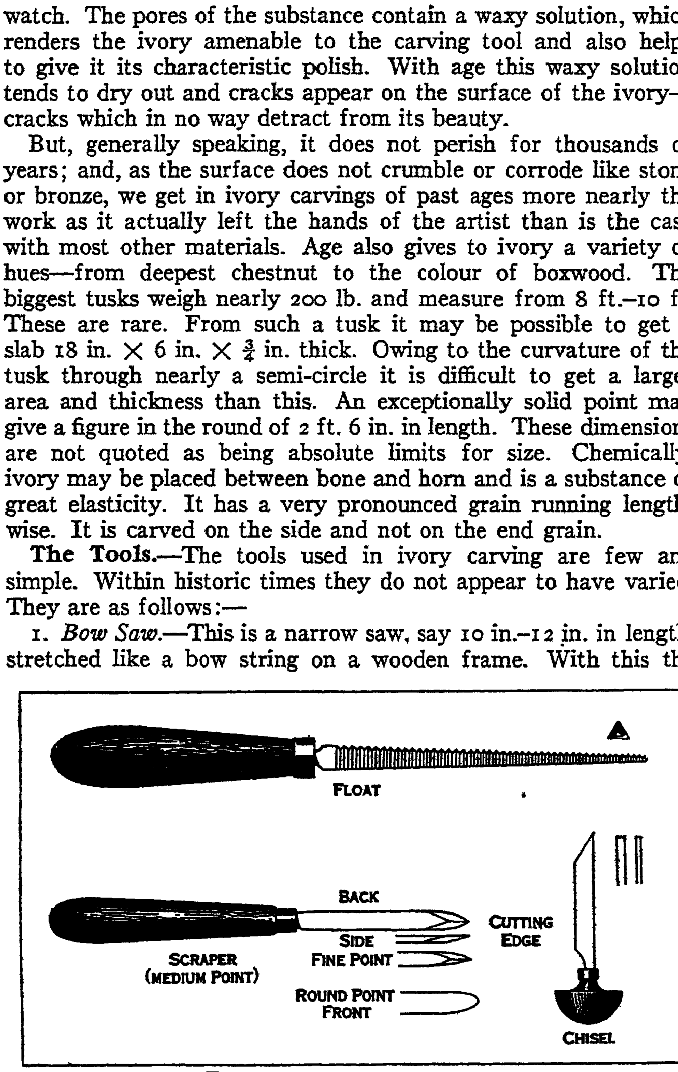
SECTIONAL VIEW OF TUSK; CURVATURE INCREASES WITH LENGTH OF TUSK

watch. The pores of the substance contain a waxy solution, which renders the ivory amenable to the carving tool and also helps to give it its characteristic polish. With age this waxy solution tends to dry out and cracks appear on the surface of the ivory—cracks which in no way detract from its beauty.

But, generally speaking, it does not perish for thousands of years; and, as the surface does not crumble or corrode like stone or bronze, we get in ivory carvings of past ages more nearly the work as it actually left the hands of the artist than is the case with most other materials. Age also gives to ivory a variety of hues—from deepest chestnut to the colour of boxwood. The biggest tusks weigh nearly 200 lb. and measure from 8 ft.–10 ft. These are rare. From such a tusk it may be possible to get a slab 18 in. × 6 in. × $\frac{3}{4}$ in. thick. Owing to the curvature of the tusk through nearly a semi-circle it is difficult to get a larger area and thickness than this. An exceptionally solid point may give a figure in the round of 2 ft. 6 in. in length. These dimensions are not quoted as being absolute limits for size. Chemically, ivory may be placed between bone and horn and is a substance of great elasticity. It has a very pronounced grain running lengthwise. It is carved on the side and not on the end grain.

The Tools.—The tools used in ivory carving are few and simple. Within historic times they do not appear to have varied. They are as follows:—

1. *Bow Saw.*—This is a narrow saw, say 10 in.–12 in. in length, stretched like a bow string on a wooden frame. With this the



TOOLS USED IN IVORY CARVING

tusk may be sawn into lengths or slabs. [*Note:* When available a small-toothed circular machine saw is much quicker, more accurate and less wasteful than the bow saw for the preliminary cutting of ivory.]

2. *Float.*—(*See* Illustration.) This is a triangular tapering tool in a wooden handle. Two of the three faces are cut across into small ridges throughout their length. By holding the handle in the right hand and forcing one of the ridged faces outwards and obliquely over the surface of the ivory, shreds of the substance

may be pared off.

3. *Gouge and Mallet.*—Small gouges, up to about ½ in., tempered as for wood-carving, may be used with a mallet. The carving should always be with the grain and the mallet must not be used with violence. Great care and some experience are necessary as the ivory will break or flake some little distance ahead of the tool.

4. *Rasp* and *File.*—Fine rasps and medium files will be found useful at many points of ivory carving.

5. *Chisel.*—(*See* Illustration p. 221.) After the roughing out has been done, this small tool comes into use. The ball handle is held firmly in the centre of the palm; the blade is held near the point between the thumb and forefinger. Considerable force must be exerted in each cut, pressure being given with the wrist and forearm.

6. *Scraper.*—(*See* Illustration p. 221.) This is the most distinctive tool used in ivory carving. It resembles a wood-carving chisel ground to a point, fine or round as required, with the front face kept flat and the rear face bevelled off into a cutting edge. It is held like a pen in the right hand: the finger tips being about 1 in.–½ in. from the point. Using the thumb of the left hand to give a steadying pressure at the point, the tool is pushed with a short flicking movement over the surface of the ivory, removing the substance in shavings. Fine pointed scrapers can be used for engraving the most delicate lines. Nearly all ivory carving is finished with the scraper.

Polishing the Carving is most effectively carried out by gently applying fine pumice powder with a soft damp cloth. In small interstices, where the finger cannot reach, a piece of wood, such as a match-stick, may be used with the damp powder. Whiting or a white tooth-powder may also be used for a final polish, if this is required.

Methods of Holding.—When carving in the round, ivory is best held in a wooden vice, or between pieces of wood, cork or thick felt inserted into the jaws of an iron vice. Ivory must never be held directly between the jaws of a metal vice, as this will cause a deep bruise. Larger pieces can often be held conveniently in the left hand at certain stages of the carving. Slabs of ivory on which a relief is to be carved should be fixed to a piece of wood of suitable size, 1 in.–¾ in. thick, by means of beeswax. The melted beeswax should be poured on to the centre of the piece of wood, the ivory pressed on to the molten wax. The wax should be in such quantity that a small amount exudes on all sides when the ivory is pressed down. When set, this superfluous wax should be scraped away before the carving is commenced, or it will get on to the hands and tools. When it is necessary to draw upon ivory, as for a relief, an ordinary lead pencil should be used. The pencil lines can be fixed by painting over the whole surface with white spirit varnish. This quickly dries into a hard transparent skin, impervious to moisture, which in no way interferes with the process of the carving. (A. Du.)

TERRA COTTA

Material.—Clay is decomposed felspathic and silicious rock (*see* Clays), varying in composition and colour according to its location. Pure clay or Kaolin, as the Chinese named it, is a residual, non-plastic, white-burning clay, not usable in its natural state but essential in the composition of porcelain and china bodies. In contrast, the impure sedimentary clays, of which all earthenware and most terra cotta sculpture are made, are plastic and in their natural state contain all the requisites for modelling (plasticity, porosity, vitrification). If these are lacking, the clay can be modified to obtain these essentials. Buff and red-burning clays in their green (or raw) state are grey, black, tan and red, but when burned these change to a light flesh colour which ranges to a deep chocolate brown, the tones modified according to the proportions of iron carried and also by the temperature reached in the firing.

A good modelling clay must have: (1) plasticity, with the ability of holding its form both while being worked and during the firing; (2) porosity, or sufficient looseness or openness in the clay particles to enable the moisture to escape in drying without shrinking too much or cracking; (3) vitrification, or the proper resistance to heat, so that it does not warp and crack in the firing or shrink excessively. The open, rather sandy clays are the more desirable.

Uses.—Sculptors have worked in terra cotta since the beginning of history, using it for the modelling of small figures, for the making of moulds and for pressing in the moulds, as well as for architectural details, friezes, tiles, roofing and façades. The amount of terra cotta objects produced is naturally governed by the workable material of the country. In Egypt and Italy it was used extensively because of the scarcity of marble and stone.

METHOD

Preparation.—A suitable clay having been located, it must be mined and cleaned of all foreign substances (stone, twigs, etc.) by washing, blunging, sieving, and then separating from the water. In modern efficient equipment the separating is done by means of a compressor which absorbs the water and leaves the clay in compact workable squares, which in turn are placed in a damp box and kept moist for use by the sculptor when needed. In primitive plants one method is to make a trough of hollow tile; into this trough the liquid clay, or slip, is poured and, because of the porous quality of the tile, the water is absorbed and evaporated, leaving the clay which can be rolled up and stored away.

Construction.—Now it is ready for the sculptor. One method of constructing a figure is to build it up on an armature, with either plasticine or clay. If clay is used, it must be kept wet either by spraying water on the figure from time to time as the work advances, or by keeping damp cloths around most of the surface, and by covering it entirely and keeping it in a damp box when not being worked. If the original is not to be cast, but to be fired directly, no armature can remain in the statue because of the twisting and burning of the wire in the fire. Usually small statuettes are made solid; but for larger figures and groups it is best to build them hollow, keeping the thickness of the clay walls as even as possible. In this method the clay requires definite preparation. It must be thoroughly wedged, which means that the clay is cut in two on a taut wire and vigorously thrown down, one piece on top of the other, to expel the air. This is done repeatedly until the clay is even in texture and uniform in moisture. If a clay is too hard, water can be poured on the clay and then the clay cut and beaten again as before. It is wise to start with approximately as much clay as the size of the figure to be constructed, working as long as possible until it begins to sag on account of the moisture. While working up to this point care should be taken when adding new clay to work it thoroughly into the old clay, making sure that no air has been allowed to enter and that the added clay is securely blended to the old. When the sculptor has worked as long as the clay will permit, the statue is allowed to dry and stiffen just enough to hold its shape, and then the sculptor will proceed as before. When the figure is ultimately accomplished, and the fine details are being developed, it is helpful to spray the figure occasionally with a very fine spray of water.

Should a mould be made, the clay is not allowed to dry but is kept in what is known as leather-hard condition, firm and hard but still moist. From this the mould is cast, and if the piece is not too intricate and has no undercuts, the original may be saved. The clay, shrinking slightly as it drys, separates itself from the plaster mould. In order to cast a difficult mould, one with small passages and many pieces, the clay must be poured. Clay in a dry state, powdered and sprinkled into water and then stirred vigorously or blunged, makes what is known as slip (a liquid clay). Slip needs to be fairly thick to prevent too great shrinkage in the drying. The mould should be dry before the pouring, and the slip free from air bubbles. Pouring the slip very slowly over the mouth of one pitcher on to the mouth of another will break the bubbles. To make the mould ready for pouring, it should be tied together securely and wedges placed between the plaster and the cord to tighten the hold. Then the slip is poured in until the mould is full and shaken gently to raise any bubbles. The slip will adhere to the dry mould, the moisture soaking into the plaster, and as the amount soaks down, more slip is poured in to fill the mould again to the top. This process is repeated until the thickness of the wall can

be seen by scraping across the mouth of the mould with a flat knife, and, if sufficient, the mould is then inverted on two or three small blocks or tiles and allowed to drain. When it begins to pull away from the mould, or is firm enough to stand by itself, it is safe to untie and separate the mould. It is stood on a flat level table, and the sculptor then begins to work over the surface, cutting away the seams which always show where the sections of the mould come together, and refinishing and retouching. The statue is then allowed to dry slowly and is ready for the fire.
